ADVERTISEMENT.

THE kind reception which the authors of this Dictionary have experienced in a book of theirs published some years ago, entitled *Every Man his own Gardener*, of which many thousands have been sold, encourages them to hope for the public favour and approbation in a work of a more extensive nature, but, at the same time perfectly consistent with their former labours.

Gardening and Botany are so nearly allied, that every professor of Horticulture ought to be a Botanist, or at least know the rudiments or principal out-lines of *Botanic Philosophy*, in conjunction with that of practical Gardening; for, as his province is the propagation and culture of plants, it is necessary for him also to know the class, order, and genus to which every plant under his care belongs, agreeable to their botanic characters and systematical arrangement.

It will be readily allowed, that several books of Gardening, from which general instruction was expected, have proved deficient, not only in the most essential parts of Practical Gardening, but also in the Botanic System; from hence it naturally follows, that many practitioners still remain ignorant of the principal branches and operations of Gardening; and the practice of Botany.— On due consideration of the defective state of the different voluminous books of Gardening, heretofore published, respecting their irregular and unintelligible arrangements,

A D V E R T I S E M E N T:

arrangements, and the impracticable and prolix directions, for performing the necessary operations; we humbly conceived, that a system of *Universal Gardening and Botany* united, would be highly acceptable, not only to practitioners, but to all others who delight in those laudable pursuits.

We have, therefore, from the result of many years extensive practice and experience in different parts of these kingdoms, diligently composed a comprehensive System of *Universal Gardening and Botany*, comprised in a moderate volume, on an original plan; comprehending, in botanical arrangement, according to the celebrated Linnæan system, all the known trees, shrubs, and herbaceous plants, natives and exotics, that are cultivated, or merit general culture either for use, ornament, curiosity, or observation; with the names of the classes, orders, genera, and of the different species of plants in each genus or family; together with the description of their general habit and structure, and all the proper botanic terms of art used in discriminating the various parts of plants.

We have also explained the different temperatures of the various trees and plants, hardy and tender, whether for the full ground or the green-house, stove or hot-bed, &c. and described the several uses of the various plants in gardening and for œconomical purposes; their proper arrangement in every department, both in the various hardy plantations, as the Nursery, Pleasure-ground, Flower-garden, Kitchen-garden, Fruit-garden, Woods, and Forests; and in the Green-house, Stove, Hot-beds, Frames, &c. With the practical method of raising or propagating every different tree and plant; and their general method of culture, in every stage of growth, in the several districts of Gardening.

The reader will find full directions, from experience, for managing the Nursery, Pleasure-ground, Shrubbery, Flower-garden, Kitchen-garden, Fruit-garden, Timber-plantations, Green-house, Stove, Hot-beds, Forcing-frames, Common-frames, &c. and also directions for performing the mechanical operations of the different methods of sowing and planting all sorts of seeds, roots, and plants,

A D V E R T I S E M E N T.

plants, in every department of Gardening and Planting. Also the operations of propagating the numerous species of trees, shrubs, and herbaceous plants, either by seed, suckers, slips, off-sets, parting roots, layers, cuttings, grafting, budding, inarching, &c. Together with the best method of performing all other mechanical operations of Gardening; and a description of the proper soils, manures, situations, and exposures for the various garden districts, and respective plants.

Some apology may be necessary for the style; but when it is considered, that perspicuity ought to be preferred to elegance, the good-natured reader will pardon little mistakes in language, if the meaning is clear and obvious.

plans, in every department of Gardening and Planting. Also the operations of propagating the numerous species of trees, shrubs, and herbaceous plants, either by seed, suckers, slips, cuttings, pressing roots, layers, cuttings, grafting, budding, inarching, &c. Together with the full instruction of forming all other mechanical operations of Gardening; and a description of the proper soils, manures, situations, and exposures for the various garden plants, and respective plants.

Some apology may be necessary for the title; but when it is considered that perspicuity ought to be preferred to elegance, the good natured reader will pardon little mistakes in language, if the meaning is clear and obvious.

T H E
UNIVERSAL GARDENER
A N D
B O T A N I S T.

A C A

ACANTHUS, formerly named *Branca Ursina*, i. e. Bears-breech.

This genus retains five distinct species, four of which are hardy herbaceous perennials of the flowery tribe, that obtain three or four feet stature, adorned at top with numerous flowers in erect spikes, and merit esteem as plants of ornament for the embellishment of the pleasure ground. The other is an evergreen shrub, of the temperature of stove exotics.

The *Acanthus* belongs to the class and order *Didynamia Angiospermia*, and its characters are,

The CALIX, three pair of leaves forming a kind of triple cup. The COROLLA, monopetalous and ringent, opening above with a mouth, hath a broad under lip, but the upper one is wanting. The STAMINA, are two short and two long filaments, having compressed antheræ. The PISTILLUM, a turbinate germen supporting a filiforme style, terminated by two acute stigma. PERICARPUM, a roundish capsule of two cells, pregnant with smooth fleshy seeds.

The species are,

¹*Acanthus Mollis*.

Smooth Acanthus.] *Acanthus* with deeply sinuated and indented, smooth, unarmed leaves.

²*Acanthus Spinosus*.

A C A

Thorny Acanthus.] *Acanthus* with deeply jagged many-pointed leaves, having each segment terminated by a thorny point.

³*Acanthus Niger*.

Shining leaved Acanthus.] *Acanthus* with sinuated, unarmed, smooth, shining leaves.

⁴*Acanthus Dioscoridis*.

Acanthus of Dioscorides.] *Acanthus* with spear-shaped entire leaves, having spinous borders.

⁵*Acanthus Illicifolia*.

Holly leaved shrubby Acanthus.] *Acanthus* with a shrubby stalk, and waved, dentated, spinous edged leaves.

The first four species are hardy, herbaceous, fibrous-rooted plants, that produce stalks annually, three or four feet high, perennial in root, but annual in leaf and stalk, they rising in spring, and perish in autumn.

The roots are composed of thick fleshy fibres, which are considerably spreading, and penetrate deep in the earth.

The leaves and flower-stalks rise immediately from the root. The leaves spread near the ground; they are large and long, generally from about ten or twelve to eighteen inches in length, and half as much in breadth. Those of the first, second, and third sorts are variously sinuated, divided, and indented, and spreading in circular clusters, and form a singularly elegant appearance. The flower-stalk

B

stalk rises between the leaves, and attains three or four feet stature, erect, round, thick, fleshy, and decorated upward with numerous flowers. The flowers are universally hermaphrodite, and formed each of one tubular petal, the colour chiefly white, and arrange themselves in a thick spike along the upper part of the stalk, each separate flower occupying a distinct cup. They appear in July and August, continue a month or six weeks, and are succeeded by plenty of ripe seed in autumn.

The *Acanthus Mollis* was greatly celebrated in ancient times for the elegance of its leaf, which attaining a considerable length and breadth, and having its edges curiously scalloped, undulated, and indented in a singularly beautiful manner, is the chief ornament of the plant.

The *Acanthus Spinosus* is also a noble plant, and demands our attention for the singularity of its large many pointed thorny leaves, which form a pleasing variety.

The above two species are the most commonly known and cultivated in the English gardens.

These plants are natives of Italy, Spain, and Portugal, but grow freely here in the full ground, and are of easy culture.

The *Acanthus Ilicifolius* is a low evergreen shrub, a native of South America, and requires the aid of a stove to retain it in this country.

Use in Gardens, Propagation, &c.

With respect to the merit of these plants in gardens; the herbaceous species may with propriety be employed as furniture for the decoration of common large borders, and other similar compartments of the pleasure ground, and they may be introduced in the shrubby clumps, toward the front, between shrubs of moderate growth. Their flowers, though not elegant, are conspicuous; which, together with the pleasing singularity of the leaves, the plants will effect the purpose both of variety and ornament.

They prosper in any common soil, and do not require any particular exposure.

The four herbaceous species may be propagated both by seed and by parting the roots.

The seed grows freely in the common ground, and should be sown in March or April, either in shallow drills, or on the surface, and raked in, or covered with earth half an inch deep. The plants will appear

in six weeks, thin them to six inches, and in autumn or spring following transplant them into the borders, where they will flower the succeeding summer.

The propagation by parting the roots may be effected in autumn or spring: the smallest off-set will readily grow; it however is not eligible to part them too small. See PARTING-ROOTS. Plant them at once where they are to continue.

Their general culture is only to allow support, when necessary, to the flower stalks, and when these decay in autumn, to cut them down.

These plants are retained in most of the nurseries for sale, particularly the Smooth and Thorny *Acanthus*.

ACAULES Plants, i. e. without a caulis, or stem. A term used by botanists expressive of plants that have no visible stalk, but grow close to the ground.

ACER, The Maple Tree.

This genus furnishes a large collection of hardy deciduous trees, being such as cast their leaves in autumn, and remain divested of them during the winter; they claim attention, some as timber trees, others for useful and ornamental purposes in gardening.

The *Acer* belongs to the class and order *Polygamia Monoecia*, and its characters are,

THE CALIX, monophyllous, five-parted, coloured, and permanent. **COROLLA**, five oval expanded petals. **STAMINA**, eight filaments with simple antheræ. **PISTILLUM**, a compressed germen and slender style, having two acuminate stigma. **PERICARPIUM**, two roundish, united, winged capsules, each containing one seed.

The species and respective varieties are,

¹**ACER Campestre.**

Common or Smaller Maple.] Maple with lobed and obtusely emarginated leaves.

²**ACER Pseudo-Platanus.**

False Platanus, Greater Maple, or Sycamore-Tree.] Maple with leaves divided into five lobes, having the edges unequally serrated, and flowers produced in a racemus.

Variety.] Sycamore-tree with variegated leaves.

³**ACER Rubrum.**

Scarlet flowering Maple.] Maple with leaves divided into five slightly indented lobes, white on the under side, and with aggregate flowers.

Variety.] Wager's flowering maple, with the largest aggregate of flowers.

⁴**ACER Saccharinum.**

Sugar

Sugar Maple.] Maple with five-parted palmated leaves, having the edges sharply indented.

¹*ACER Platanoides.*

Platanus-leaved Norway Maple.] Maple with smooth shining leaves, divided into five sharp-pointed and acutely indented lobes, and flowers produced in a corymbus.

Variety.] Norway maple with variegated leaves.

²*ACER Pennsylvanicum.*

Pennsylvanian Mountain Maple.] Maple with leaves having three acuminate and sharply serrated lobes, and flowers produced in a racemus.

³*ACER Negundo.*

Ash-leaved Virginia Maple.] Maple with leaves composed of several distinct lobes, and with flowers produced in a racemus.

⁴*ACER Monsperfulanum.*

Montpelier or French Maple.] Maple with shining leaves, having three lobes with entire edges.

⁵*ACER Opalus.*

The Opalus or Italian Maple.] Maple with large roundish lobated, slightly cut leaves, and flowers produced in a racemus.

⁶*ACER Creticum.*

Cretan or Levant Maple.] Maple with leaves divided into three lobes, having the edges entire, and the under side a little downy.

⁷*ACER Tartaricum.*

Tartarian Maple.] Maple with oblong heart-shaped, slightly lobated, and unequally serrated leaves.

All the above species and respective varieties are of the tree kind, deciduous, and of hardy temperature, that prosper in almost any soil and exposure, in common with other hardy deciduous trees.

Most of the species, except the *Acer Campestre* and *Pseudo-platanus*, are natives originally of distant climates, some of America, and others of different parts of the continent of Europe, and the countries annexed to their names; but most of the sorts are now cultivated in the English nurseries, for the supply of noblemen and gentlemen's plantations.

These trees are of stature from about twenty to forty feet or upward, the Greater Maple frequently exceed that height, and the Norway, Ash-leaved, Sugar, and Italian Maple are likely to attain that height at least in this country; but the other species rarely obtain

more than twenty or thirty feet stature. Most of the species branch out irregularly at first, but in time form pretty full and regular heads, ornamented chiefly with opposite leaves. The leaves are universally simple, except the *Acer Negundo*, and are from about three to six or eight inches broad, and generally divided into three or five lobes, some but slightly, others deeply divided; and some have the edges of the lobes entire, others indented, and some are serrated or sawed, by which distinction the different species may with facility be detected. The flowers arise chiefly from the sides of the young branches, and are produced in a racemus, and some in a corymbus, &c. appearing in spring and early in summer, and are succeeded by ripe seed the beginning of autumn.

Most of the sorts ripen seed perfectly in England, which is remarkably free of growth, as is evident by that which scatters promiscuously from the trees, from which many young plants often rise naturally, particularly the Common and Greater Maples.

The *Common Maple* grows wild in woods and hedges. This tree attains but a moderate stature, and its foliage is small: it is sometimes admitted for variety in extensive plantations.

The *Greater Maple* is a stately tree, of free growth, decorated with luxuriant foliage, that afford a delightful shade, and both the plain and variegated sort effect an agreeable diversity in ornamental plantations.

The *Acer Rubrum* is a tree of moderate growth, the leaves are large, and the flowers have great beauty, particularly those of the second variety, i. e. Sir Charles Wager's Flowering Maple, which arise in numerous large clustering heads, and are extremely conspicuous and ornamental.

The *Acer Saccharinum*, *Platanoides*, and *Ash-leaved Maples*, are all three large growing trees, and are proper to be employed in outward plantations; as their leaves are of different sizes and shapes, and of lighter and darker shades, they afford a pleasing variety: if some trees are dispersed in parks and other extensive places, they will diversify the general scene; the corymbus flowers of the *Acer Platanoides* have singular beauty; and the sort with variegated leaves forms a pretty diversity.

The first of the above three trees, i. e. *Sugar Maple*, obtained the name from the circumstance of its imparting a great quantity of

sweet juice, with which a tolerable good sugar is prepared. This juice is obtained by piercing or tapping the trees, and from which parts the juice continue to issue for several days. This is greatly practised in America, where the trees are large and numerous. The property of the sweet juice is not however limited to this particular species, for even the Greater Maple, and some other large kinds, are found to emit great quantities, little inferior to that of the species under consideration.

The *Pennsylvanian* and *Montpelier Maples* are trees of moderate growth, and the leaves are of a middle size; those of the latter are of a thick consistence, have a shining surface, and continue late in autumn, which render them of esteem for ornamental purposes.

The *Acer Opalus* is a noble tree; it acquires a considerable stature, hath a spreading head, adorned with large and beautiful foliage.

The *Cretan* and *Tartarian Maple* are trees of humble stature, and are very proper for interior plantations.

Uses in Gardening, Propagation, &c.

For purposes in gardening, most of the species are proper to be employed in ornamental plantations and parks, and other extensive departments, in assemblage with other hardy deciduous trees of similar growth; in forming detached clumps, groves, thickets, avenues, shade for spacious walks and rural seats; and in forming running or continued plantations on the boundaries of extensive lawns, parks, &c.

All the sorts may be propagated with great facility by seed, and most of them may likewise be increased by layers and cuttings.

The seed grows freely in the common ground, and the time of year for sowing it is autumn, soon after it is ripe, or early in spring; but the former is generally the most successful season, as that of the spring sowing is apt to rise straggling. Choose a light mellow spot, and after being dug, divide it into one or more beds, three or four feet wide; smooth the surface and sow the seeds thereon, and cover them a little more than half an inch deep. The plants will appear in April or May, and by Michaelmas they will be eight or ten inches high; when, or in the ensuing spring, some of the largest may be transplanted, and in autumn following the whole; planting them in the nursery in rows two feet and half distance.

They should be permitted to have at least four or five years growth in the above nursery, or till they have attained five or six feet stature, when they may be employed in plantations.

The propagation by layers and cuttings may be performed in autumn; choose the shoots of the young branches, and in one year they will be well rooted. See **LAYERS** and **CUTTINGS**.

The variegated kinds are increased either by layers, cuttings, or inoculation, though sometimes the sycamore comes variegated from the seed of the same kind; but the most certain means of obtaining them is by the above methods, when every plant so raised will have the same variegations as the parent tree.

All the varieties of these trees are propagated for sale in most of the nursery gardens.

ACETOSA, Sorrel. See **RUMEX**.

ACHILLEA, Milfoil, Yarrow, and Sneezewort.

The plants of this genus are herbaceous fibrous rooted perennials, of hardy growth; some merit esteem for medical purposes, and some as plants of ornament.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] The **FLOWER** is compound and radiated. **CALIX**, the common cup is oval and imbricated. **COROLLA**, several tubular hermaphrodite florets compose the disk, and five flat female florets the radius. **STAMINA**, five capillary filaments in each hermaphrodite floret. **PISTILLUM**, a small germen, slender style, and obtuse stigma. **PERICARPIUM** none, the seeds being lodged in the calix.

There are twenty species, those that demand attention are,

¹**ACHILLEA Millefolium**.

Common Milfoil or Yarrow.] Achillea with doubly pinnated leaves, the lobes cut into many narrow segments and white umbels.

Variety.] Common Milfoil with purple umbels.

²**ACHILLEA Ptarmica**.

Ptarmica or Common Sneezewort.] Achillea with spear-shaped pointed leaves, having the edges sharply serrated, and white umbels.

Variety.] Ptarmica with double flowers.

³**ACHILLEA Ageratum**.

Ageratum or Sweet Maudlin.] Achillea with spear-shaped obtuse leaves, with the edges acutely sawed, and yellow umbels.

Variety.] Long-corymbus flowered sweet Maudlin.

⁴**ACHILLEA**

A C H

⁴*ACHILLEA Tomentosa.*

Hoary, bright, yellow Milfoil.] Achillea with pinnated, rough, hoary leaves; the lobes very narrow and indented, and bright yellow umbels.

⁵*ACHILLEA Clavenna.*

Pinnatifid hoary Alpine Sneezwort.] Achillea with pinnatifid, plain, obtuse, hoary leaves, and flat white umbels.

⁶*ACHILLEA Nana.*

Dwarf hoary Alpine Milfoil.] Achillea with pinnated and indented downy leaves, and globular white umbels.

⁷*ACHILLEA Ægyptiaca.*

Ægyptian hoary Sneezwort.] Achillea with pinnated hoary leaves, the lobes obtusely spear-shaped, fawed, and indented, and yellow umbels.

⁸*ACHILLEA Abrotanifolia.*

Southernwood-leaved Milfoil.] Achillea with pinnated, supra-decompound, hoary leaves; the segments very narrow, and stand remote, and yellow umbels.

⁹*ACHILLEA Macrophylla.*

Long fever-few-leaved Sneezwort.] Achillea with pinnated, deeply ferrated, plane leaves; the outermost wings the largest, and loose white umbels.

¹⁰*ACHILLEA Pubescens.*

Downy Tansey-leaved Sneezwort.] Achillea with pinnated downy hoary leaves, the lobes spear-shaped, deeply cut and ferrated, and pale yellow umbels.

¹¹*ACHILLEA Nobilis.*

Noble or Sweet Milfoil.] Achillea with doubly pinnated, finely divided, sweet scented leaves, the lower ones plane and naked, the upper obtuse and downy, and a convex white umbel.

Variety.] Noble Milfoil with pale red umbels.

¹²*ACHILLEA Santolina.*

Lavender-cotton-leaved Eastern Sneezwort] Achillea with indented bristly hoary leaves, the denticles almost entire, awl-shaped and reflexed, and large yellow umbels.

Of the above species, the *Purple Milfoil*, *Double Ptarmica*, and *Achillea Tomentosa* are the most commonly known and cultivated.

All the species are hardy herbaceous perennials, that prosper in any common soil, and obtain from six inches to three feet stature, surmounted by flowery umbels.

The roots are fibrous, which in many species creep in a horizontal direction, and multiply exceedingly.

A C H

The leaves and flower-stalks rise from the root annually. The stalks attain different heights, from half a foot to a yard or upward, decorated with leaves, and terminated by the umbels of flowers. The leaves in some are simple, but in the greater part winged or pinnated, and divided into a multitude of minute segments, in the manner of tansey, wormwood, chamomile, &c. which in most species possess different degrees of hoariness, and have an ornamental effect in a garden.

The flowers singly are small, but numerous, many being produced together from the summit of the stalks, in a sort of umbel or rather corymbus, appearing in June, July, August, and September, and are succeeded by ripe seed in autumn.

The two first species grow naturally in England, all the others were obtained from distant parts, as the Alps, France, Spain, Italy, and the Archipelago, &c.

The *Achillea Millefolium* and *Ptarmica* attain two or three feet stature. The common species grow wild in pastures, woods, and sides of banks. They are esteemed for medical uses; and the two varieties, *Purple Milfoil* and *Double Sneezwort* are admitted in gardens as ornamental plants. The roots of the *Common Sneezwort* are remarkable for provoking sneezing; and being acrid, a bit chewed in the mouth, often procures a temporary respite in the tooth-ach.

The *Sweet Maudlin* rises two feet high, the leaves impart a fragrant odour. The common species is cultivated for medicine, and the variety is retained as a flowering plant.

The *Achillea Tomentosa*, *Clavenna*, *Nana*, and *Ægyptiaca*, are of humble growth, seldom obtaining more than from six to twelve inches height, have very hoary leaves, and adorned with moderately large, compact, and very ornamental umbels.

The other five species grow from eighteen inches to a yard high, the leaves chiefly hoary, and the umbels large.

Use in Gardens, Propagation, &c.

For purposes in gardens, the singularity of the hoary leaves of many sorts form a pretty variety, and the flowers being conspicuous, and continue two or three months, render the plants proper furniture for common borders, and the fronts of shrubbery compartments.

All the sorts may be readily propagated by parting the roots any time in autumn or spring, and some also by slips and cuttings of the

the stalks, &c. in a shady border in summer.

Many of the sorts furnish plenty of seed, by which they may likewise be raised by sowing them in March or April, in a bed of light earth, and the plants will be fit to transplant for good at Michaelmas, and will flower the following summer.

ACHRAS, Sapota-Tree,* or Mammee Sapota.

This genus retains but two species, which are of the tree kind, natives of the warm parts of America; their merit here is merely for variety, and require the constant aid of a stove.

Class and order, *Hexandria Monogynia*.

Characters.] **CALIX**, six acute permanent leaves. **COROLLA**, five heart-shaped petals joined at the base. **STAMINA**, six short filaments, having arrow-pointed antheræ. **PISTILLUM**, an oval germen, a short style, and blunt stigma. **PERICARPIUM** is of the apple kind, containing one or two oval hard nuts.

The species are,

¹**ACHRAS Sapota**.

Common Sapota-Tree] Achras with oblong oval leaves, and smooth top-shaped fruit.

²**ACHRAS Mamosa**.

The Mammee Sapota of the West Indies.] Achras with spear-shaped leaves, large oval fruit, both ends terminating in a sharp point.

These trees in America rise thirty feet high, but those cultivated here in our stoves appear as shrubs; the leaves are large, those of the second sort approach near a foot in length, the flowers are of a cream colour, and are succeeded by a kind of apple, consisting of thick succulent pulp, of a luscious taste.

Both the species are propagated here by seed, i. e. the nuts or stones included in the fruit, which must be procured from the West Indies, and as soon as they arrive, planted in pots, and plunged in a hot-bed under frame and glass, or in the bark bed in the stove.

Their culture is the same as other woody exotics, of similar temperature. See **STOVE PLANTS**.

ACHYRANTHES.

The plants are chiefly herbaceous, and somewhat shrubby perennials, exotics, of the temperature of green-house and stove plants, retained more for variety than beauty.

Class and order, *Pentandria Monogynia*.

Character.] **CALIX**, five acute stiff permanent leaves. **COROLLA**, none. **STAMINA**, five filaments with small antheræ. **PISTIL-**

LUM, a single style having a bifid stigma. **PERICARPIUM** none; one roundish seed lodged in the calix.

There are eight or nine species, but possessing little merit, there is but one sort commonly known among gardeners, which is,

ACHYRANTHES Aspera.

Common Sicilian and American Achyranthes.] Achyranthes with erect stalk, oblong pointed leaves, and adpressed spikes of flowers, having reflexed cups.

The plant rises a yard high, decorated with oblong leaves, and long spikes of apetalous flowers, which proceed from the ends of the branches, appearing in July and August, and ripen seeds in September.

This plant should be potted and kept in the stove, or good green-house, in winter.

The propagation of this plant may be effected by seed and by cuttings, assisted by a hot-bed.

The following are some of the other species of less note.

¹**ACHYRANTHES Lanata.**] Woolly cupped African Achyranthes, with whorled spikes.

²**ACHYRANTHES Indica.**] Indian Achyranthes, with oval waved leaves and reflexed flowers.

³**ACHYRANTHES Sanguinolenta.**] Bloody leaved Achyranthes.

⁴**ACHYRANTHES Lappacea.**] Climbing lappaceous fruited Achyranthes.

⁵**ACHYRANTHES Muricata.**] Shrubby prickly cupped Achyranthes, with alternate leaves.

These are chiefly of the tribe and temperature of the common species.

ACONITUM, Aconite, Monk's-hood, or Wolf's-bane.

This genus furnishes several species of hardy herbaceous perennials, esteemed as ornamental garden plants, obtaining in stature from two to six feet, their stems terminated by elegant spikes of flowers.

Most of the plants of this genus possess a poisonous quality.

Class and order, *Polyandria Trigynia*.

Characters.] **CALIX**, none. **COROLLA**, composed of five irregular petals, one placed above, one below, and two sideways, the upper one formed like a hood, and covers the other parts; and in the bottom are two nectariums. **STAMINA**, numerous filaments, having erect antheræ. **PISTILLUM**, three or five germina, as many styles, surmounted by reflexed stigma. **PERICARPIUM**, three or five

five oblong capsules, of one cell, filled with angular seeds.

The species of most note are,

¹*ACONITUM Pyramidale.*

Common Pyramidal blue Aconite.] Aconite with leaves divided into many narrow segments, and very long pyramidal spikes of blue flowers.

²*ACONITUM Lycoctonum.*

Poisonous yellow Aconite.] Aconite with palmated, finely divided, hairy leaves, and yellow spikes of flowers.

Variety.] Large poisonous yellow Aconite, with palmated smooth leaves.

³*ACONITUM Anthora.*

Salutiferous or Wholesome yellow Aconite.] Aconite with leaves divided into many long narrow segments, and sulphur-coloured spikes.

⁴*ACONITUM Napellus.*

Napellus or Large blue Aconite.] Aconite with leaves cut into many linear segments, the upper ones broadest and marked with a line, and large blue flowers.

Varieties.] Rose-coloured Napellus.—White-flowered Napellus.—Variegated blue and white Napellus.

⁵*ACONITUM Pyrenaicum.*

Pyrenaean squamous leaved yellow Aconite.] Aconite with leaves divided into long segments, these deeply jagged into many narrow parts, and lie over one another like scales, and pale yellow spikes.

⁶*ACONITUM Cammarum.*

Wedge-lobed Aconite.] Aconite with leaves divided into many wedge-shaped lobes, these cut into many acute parts, and large violet-coloured flowers.

Varieties.] Wedge-lobed purple Aconite.—Wedge-lobed blueish purple Aconite.—Wedge-lobed deep blue Aconite.

⁷*ACONITUM Orientale.*

Eastern tall white Aconite.] Aconite with palmated leaves, and large white flowers.

⁸*ACONITUM Variegatum.*

Variegating dwarf blue Aconite.] Aconite with many parted leaves, the segments half cut through, the upper ones the broadest, and small spikes of variegating blue flowers.

The above eight species and respective varieties are all of the herbaceous tribe, and have perennial roots, but the leaves and stems are renewed annually in the spring, and perish in autumn.

The roots of the common sorts are thick fleshy tubers, and those of all the species send forth many fibres, and multiply greatly.

The stems or flower stalks rise annually from the root, which in different species attain different heights, from two to six feet, erect, round, firm, and closely ornamented with leaves below, and numerous flowers upward, arranged in a beautiful erect spike, from one to two feet long. The leaves are large and universally simple, but deeply divided in the palmated manner into many long segments; and in some, these again are variously jagged, lacinated, or subdivided into many narrow parts in different arrangements, that in the whole the leaves form a singularly pretty variety.

The flowers arise along the upper part of the main stem, surrounding it in great numbers, and as the top advances in height, it furnishes a daily succession six or eight weeks, and all the sorts afford plenty of seed in autumn.

The season of flowering is from the middle of May until September; the *Aconitum Pyramidale* is the first in bloom.

Use in Gardens, Propagation, &c.

Considered as ornamental plants, they make a tolerable appearance; their flowers continue long, which, together with the diversity of their leaves, afford a source of variety to the curious. They are adapted for large borders, and may be introduced in vacant spaces in shrubbery clumps, the compartments on the boundaries of lawns, or those contiguous to shady walks, &c. as they will succeed between and under trees where the shade is not considerable, particularly the common blue sorts.

Great caution ought however to be used in admitting them in parts of a garden where children frequent.

With respect to the bad quality of these plants; they, taken inwardly, prove a deadly poison, and the effluvia of the flowers communicate their noxious quality in some degree. It is remarkable that the blue Aconites are much more virulent than the yellow kinds. The root of the *Aconitum Anthora* is accounted an antidote to the poison of all the other species, and is the sort that is used in medicine. It is however affirmed, that if this sort grow near any of the others, it attracts their baneful property, and becomes like them poisonous.

Of the bad qualities of these plants, many avail themselves to get rid of vermin. A decoction of the roots destroy bugs; the same part powdered and administered in bread, or any

any other palatable vehicle, to rats and mice soon proves mortal.

All the species, &c. are easily propagated by seed, also by parting the roots, which, of the common sorts, every bit having an eye or bud, will readily grow.

The seed grows freely in a bed or border of common earth, and may be sown early in spring, or rather in autumn, soon after it is ripe, and in April or May following the plants will appear; give occasional weeding and watering until the beginning of August, then prick them three or four inches distant in a shady border, and in autumn or spring after transplant them where they are finally to remain.

The propagation by dividing the roots may be effected any time from October till March.

The chief culture they require is to have their decayed stalks cut down in autumn.

The plants are natives chiefly of the Alps, Pyrenæan, Helvetian, and other mountainous parts of the continent. The common blue sorts have been long inhabitants of almost every garden, and all the others may be had at the nurseries.

ACORN, a kind of nut, and is the fruit of all the sorts of oak, evergreen oak, and cork-trees. See *QUERCUS*.

ACORUS, Sweet Rush, or *Calamus Aromaticus*.

There is but one known species, which is a hardy herbaceous perennial of the flag kind, and grows wild, but having a fragrant aromatic odour, is admitted in gardens.

The class and order, *Hexandria Monogynia*.

Characters.] CALIX none. COROLLA, six concave petals, and the flowers arranged in a sort of amentum. STAMINA, six filaments, having double antheræ. PISTILLUM, a rising germen, no style, but a small prominent stigma. PERICARPIUM, a short triangular capsule, containing oval seeds.

The species is,

ACORUS Calamus.

Calamus Aromaticus, or Sweet Rush]

The plant is a sort of aquatic, it growing naturally in ditches and watery places.

It hath thick jointed roots, long narrow leaves, and flowers produced in a sort of amentaceous spike, supported upon a kind of leaf-like stalk, appearing in June and July.

The plant grows wild in many parts of the kingdom, and the roots may be transplanted in autumn into any moist soil of a garden,

but unless the roots are in water they rarely flower.

The nursery gardeners cultivate the plant for sale.

ACTÆA, Herb-Christopher, or Bane-Berries.

The plants are herbaceous perennials, of hardy temperature, and tall growth, and esteemed as plants of ornament, being adorned with curiously branched leaves, and numerous snow-white flowers, in large spikes.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, four concave blunt deciduous leaves. COROLLA, four large obtuse petals. STAMINA, many filaments, having erect double antheræ. PISTILLUM, an oval germen, no style, the germen crowned by a depressed stigma. PERICARPIUM, one oval globular berry, of one cell, containing four seeds.

There are five or six species, those that claim attention are,

¹ACTÆA *Spicata.*

Common ramose spiked Herb-Christopher, with black berries.

²ACTÆA *Alba.*

White berried American Herb-Christopher.] ACTÆA with a tuberous root, compact oval spike, and white berries.

³ACTÆA *Racemosa.*

Clustered long spiked American Herb-Christopher.] ACTÆA with tallest stalks, and very long reflexed spikes.

The first sort grow naturally in woods in many parts of England, the others were obtained from North America.

The plants are perennial in root, but the leaves and stems rise annually in spring, attain three or four feet stature, flower in summer, and decay in autumn.

The roots are composed of thick fibres, those of the second are tuberous and knobbed.

The stems or flower stalks of the first and second sorts rise two feet and half high, that of the third often four or five; they grow erect, and are adorned below with leaves, and the upper part with numerous flowers, arranged in very ornamental spikes terminating the stalks. The leaves are both radical and elevated on the stalks, they are compound, branched; very long, and composed each of twenty-seven lobes or folioles, the common foot-stalk of each leaf branching or dividing by threes into nine smaller, each of which sustain three lobes, and in some the radical or root leaves, including their folioles, approach two feet in length.

The

The flowers are snowy white, and their numbers in each spike render them very conspicuous and pretty; they appear in May, June, and July, and those of the first and second are succeeded by seed in autumn, but the third rarely produce any in England.

The seed of these plants are contained in small berries, the size of peas.

These berries are supposed to be noxious in their quality. A single berry of the common sort is said to be instant death to poultry and other birds.

As furniture for the pleasure ground, all the three species may be employed in any of the common compartments, and are adapted for shady borders, but not immediately under trees, and may occupy vacant spaces between deciduous shrubs in the most conspicuous parts of shrubberies.

Their propagation may be readily effected by seed in the common ground, which may be sown in the spring or autumn; it however is observable, that when sown in autumn, the plants rise freely the following spring, and those of the spring sowing are apt to rise straggling.

Transplant them in autumn where they are to continue, and they will flower the following year.

ACULEUS, (a Needle.) By botanists it is expressive of a prickle or sharp point, a species of armature with which the stems and branches of several plants are furnished, exemplified in the rose, raspberry, &c.

The prickle here alluded to differs from the spine or thorn, *spina*, as being only a prolongation or detached portion of the outer bark of the plant, as is apparent by such prickles being readily detached from the stem or branch along with the bark; whereas, the spine or thorn is more rigid and protruded from the wood of the plant, such as in hawthorn, buckthorn, three-thorned acacia, &c. and cannot be detached without rending some part of the substance of the wood. See *SPINA*.

ADANSONIA, *Æthiopian Sour Gourd*, or *African Calabash-Tree*.

This genus furnishes but one known species, which is a deciduous tree, of amazing bulk in its native soil, which is Africa, and is retained here in stoves as a curiosity.

Class and order, *Monadelphia Polyandria*.

Characters.] **CALIX** is cup-shaped, five-parted at the brim, and deciduous. **COROLLA**, five roundish petals. **STAMINA**, numerous filaments united below into one body,

and kidney-shaped antheræ. **PISTILLUM**, an oval germen, many-branched style, having as many hairy stigma. **PERICARPIUM** large, oval, membranous capsule of many cells, filled with a fungous sour pulp, containing many seeds.

The species is,

ADANSONIA *Baobab*.

Baobab, or Æthiopian Sour Gourd.]

The tree is a native of Senegal, and other parts of Africa, where it attains an enormous size, adorned with digitate leaves, of three or five spear-shaped spreading lobes.

With respect to its merit in this country, we only consider it merely as a plant of singularity, and requires the indulgence of a stove. It is propagated by seed procured from abroad, which should be sown in pots, and plunged either in a substantial hot-bed, under glasses, or that in the hot-house, in which department the plants must be always retained.

There are some plants now in England twelve or fifteen feet high.

This monstrous tree derives its present name *Adansonia*, given by Linnæus, in honour of Mr. Adanson, an eminent French botanist, who travelled in Senegal, and saw many of the trees growing, and the description he gives of their enormous bulk is truly amazing.

The diameter of the trunk, he says, frequently exceeds twenty-five feet, and its spreading top that of a hundred and twenty, and each branch equal to a monstrous tree in Europe, and the horizontal roots have measured upwards of an hundred feet long, and yet, amazing as these dimensions are, the tallest trees rarely exceed sixty or seventy feet. The age of the tree is perhaps no less remarkable than its enormous size, for as the same gentleman relates, he discovered some trees about five or six feet diameter, on the bark of which were deeply engraved or cut many European names, some of which were dated, which inscriptions he thinks sufficient to determine pretty near the age the trees may attain, as supposing those in question, according to the date, grew six feet diameter in two hundred years, how many centuries must be requisite to give them the astonishing diameter of twenty-five feet!

ADENANTHERA, *Bastard Flower-Fence*.

The plants are of the tree kind, evergreen, and exotics, of the growth of India, and retained here in stoves by way of variety.

Class and order, *Decandria Monogynia*, ten stamina, one style.

Characters.] CALIX monophyllous, and five-parted at the brim. COROLLA campanulated, and formed of five reflexed petals. STAMINA, ten filaments with roundish antheræ. PISTILLUM, an oblong germen, one style, and single stigma. PERICARPIUM, a compressed pod, having many smooth seeds.

The species are,

ADENANTHERA *Pavonina*.] Adenantha with decompound or branching smooth leaves.

ADENANTHERA *Falcataria*.] Adenantha with decompound leaves, woolly on the upper sides.

These trees attain a large size in India. Both species are adorned with large and beautifully branched leaves, the singularity of which are the merit of the plants in this country.

They are raised from seed procured from abroad, and its vegetation must be effected by artificial heat, the plants kept in pots, and continued always in the stove.

ADIANTHUM, *Capillus Veneris*, or Maiden-hair.

The plants are herbaceous and perennial; there are many species, one or two of which are admitted in gardens for variety.

This genus is of the class *Cryptogamia*, flowers imperfectly visible.

Characters.] The plants are of the fern tribe, whose flowers are either entirely concealed or imperfectly visible, see FILICES; which, in the plants in question, are fixed in numerous small spots upon the back of the leaves, the points of which are reflexed.

The species that merit notice are,

¹ADIANTHUM *Capillus Veneris*.

True Maiden-hair.] Adiantum with decompound, alternate, wedge-lobed leaves.

²ADIANTHUM *Pedatum*.

Foot-shaped Canadian Maiden-hair.] Adiantum with foot-shaped pinnated leaves with gibbous lobes, and fructifications in the divisions.

The first sort is a native of France, Italy, and places adjacent; the second of Canada, and both require shelter from frost.

The roots are fibrous and creeping.

With respect to their stems, they are not to be distinguished from the foot-stalks or ribs of the leaves, as is common to most of the fern tribe, see FILICES; they, in both species, divide into many leaves, which, in

the *Capillus Veneris* are like those of coriander, and fragrant and agreeable in taste.

Both these plants are propagated by dividing their roots, which should here be planted in pots of dry soil.

ADONIS, *Flos-Adonis*, i. e. Adonis Flower, sometimes called Bird's-eye.

This genus retains several species of herbaceous plants, of the flowery race; two are annual, the others perennial, of stature from twelve to twenty inches, and with every stalk, branch, and shoot, terminated by solitary flowers.

Class and order, *Polyandria Polygynia*.

Character.] CALIX pentaphyllous, coloured, and deciduous. COROLLA, from five to twelve petals. STAMINA, many short filaments, having reflexed antheræ. PISTILLUM, many germina and stigma. PERICARPIUM none, many naked seeds being attached to the pedicle, forming an obtuse spike.

There are five species; those of note are,

¹ADONIS *Annua*.

Common annual red Adonis.] Adonis with flowers having sometimes eight petals, these red and marked with dark spots.

²ADONIS *Æstivalis*.

Summer flowering yellow annual Adonis.] Adonis with flowers, having generally five petals, of a pale yellow colour.

³ADONIS *Vernalis*.

Spring flowering yellow perennial Adonis.] Adonis with large yellow flowers, having about twelve petals.

The two first sorts are annual, i. e. the plants come up, attain their full growth, flower, perfect their seeds, and perish root and branch the same year. They are of bushy growth, from twelve to eighteen inches high, branching every way from the bottom, decorated with abundant foliage, finely cut or divided, and the ends of all the branches and lateral shoots are adorned with flowers, which stand singly.

These two flower in May, June, and July, and the seeds ripen in autumn.

The third sort is perennial in root, which is fibrous, but the stalks are renewed annually.

The stalks of this rise eighteen or twenty inches high, several arising from the same root, each of which is surmounted by a large yellow flower, which appear in April, and the seeds ripen in autumn.

All the three species are proper furniture for

for common borders, or to adorn the fronts of the shrubby compartments, in assemblage with other herbaceous plants.

Their propagation is by seed in the common ground, sown in autumn, or early in the spring, i. e. February or March. The third sort also by off-sets of the roots.

The two first sorts should be sown in the places where it is designed the plants are to flower, for they do not succeed by transplantation; it is most eligible to sow them in small patches, see **HARDY ANNUALS**, covering the seed near half an inch deep; when the plants are two inches high, thin them, leaving only three of the stoutest in each patch; their farther culture is occasional weeding and watering.

If the seed of these two are sown in autumn, i. e. September or October, the plants flower earlier by a month or two than those of the spring sowing, as is evident by the plants arising from the scattered or self-sown seeds.

The following are also of this genus.

ADONIS Apennina.] Apennine Adonis with large flowers, having fifteen petals.—**ADONIS Capensis.**] Cape Adonis with doubly ternate leaves, the lobes cut and indented.

ADOXA, Tuberous Moschatel, or Hollow-root.

There is but one species, a tuberous rooted, hardy, herbaceous perennial, of diminutive growth, esteemed as a flowering plant.

Class and order, *Oelandria Tetragynia*.

Character.] **CALIX**, monophyllous, bifid, and permanent. **COROLLA**, monopetalous, divided into four acute segments. **STAMINA**, eight filaments with roundish antheræ. **PISTILLUM**, the germen resting upon the calix, supporting four styles. **PERICARPIUM**, a round berry of four cells, containing four seeds.

The species is,

ADOXA Moschatellina.] Moschatel or Muls-smelling Adoxa, with a bulbous fumitory leaf.

The plant grows wild in woods and shady places, and is admitted in gardens more for variety than beauty.

It grows five or six inches high, the root is tuberous and pointed, from which rise small leaves, having many minute lobes, the stalk is slender, and adorned at top with four or five small whitish flowers, which appear in April, and the berries ripen in May.

The propagation of this plant is by the off-

sets of its root, when the leaves decay in summer.

It prospers best in the shade.

ÆSCHYNOMENE, Bastard Sensitive Plant.

There are six species, three or four of which are annual, the others perennial, of somewhat shrubby growth, natives of hot climates, and preserved here in stoves for variety.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX** monophyllous, cut into two parts, the upper segment bifid, the lower trifid. **COROLLA** is *papilionaceus*, or butterfly-shaped, the standard large and heart-formed, the wings short and oval, and the keel long and moon-shaped. **STAMINA**, ten filaments; nine united, one separate. **PISTILLUM**, an oblong germen, arched style, and simple stigma. **PERICARPIUM**, an oblong deeply-jointed pod, each articulation having one seed.

The species that merit notice are,

¹**ÆSCHYNOMENE Aspera.**

Rough stalked Æschynomene.] Æschynomene with rough herbaceous stalks, and deeply jointed rough pods.

²**ÆSCHYNOMENE Arborea.**

Tree Æschynomene.] Æschynomene with a tree-like smooth stem, smooth jointed pods, with the articulations half heart-shaped.

³**ÆSCHYNOMENE Grandiflora.**

Great flowered Æschynomene.] Æschynomene with a tree-like stem, large flowers, and long slender pods.

⁴**ÆSCHYNOMENE Sesban.**

Egyptian obtuse lobed Æschynomene.] Æschynomene with a smooth stem, leaves having obtuse lobes, and cylindrical equal pods, not jointed.

The first species is chiefly annual in this country; the others are perennial both in root and stem in their native soil, and may be continued so here by the aid of a stove.

They obtain in height from four to seven feet, the stem of the first is herbaceous, and attain four feet height; that of the others is woody, and rise seven feet high, erect, and divide into branches upward, where all the species are closely adorned with leaves, which are universally winged, and composed of many folioles or lobes, arranged along each side of the middle rib. The flowers issue from the angles of the leaves; they are composed each of four petals, and are of the pea-bloom form, arise two or three together, the colour chiefly yellow,

yellow, those of the fourth sort in long pendulous spikes, and assume a copper colour, appearing in summer, and are succeeded by long legumense pods in autumn.

The propagation of these plants is by seed, assisted by a hot-bed in March or April; when the plants are two or three inches high, transplant them into separate small pots, and plunge them in the hot-house.

ÆSCULUS. The Horse-Chestnut-Tree.

There are but two species and some varieties, all of which are hardy deciduous trees, esteemed principally for purposes of ornament in gardens and parks, &c.

Class and order, *Heptandria Monogynia*.

Characters.] **CALIX** is monophyllous, and five-parted at the brim. **COROLLA**, five roundish petals inserted into the calix. **STAMINA**, seven declinated filaments, having erect antheræ. **PISTILLUM**, a roundish germen, single style, and pointed stigma. **PERICARPIUM**, the calix becomes a large round prickly capsule of three cells, including one or two nuts.

The species and varieties are,

¹**ÆSCULUS** *Hippo-castanum*.

Common Horse-Chestnut.] **Æsculus** with digitate leaves, having seven entire lobes, seven stamina to the flowers, and prickly capsules.

Varieties.] Common Horse-Chestnut with gold striped leaves.—Common Horse-Chestnut with silver striped leaves.

²**ÆSCULUS** *Pavia*.

Pavia or Scarlet Horse-Chestnut.] **Æsculus** with digitate leaves, having five or six sawed lobes, red flowers, having eight stamina and smooth capsules.

The first species is originally a native of Asia, the second of America, but both sorts are extremely hardy, and prosper here in any common soil or exposure.

The Common Horse-Chestnut and varieties grow thirty or forty feet high. The trees assume a formal growth, the branches extending regularly on every side, and diminish so gradually in length from the bottom upward, as to give the head a beautiful conic form, which in summer is abundantly furnished with luxuriant foliage, and adorned with innumerable large spikes of white flowers, tinged with red, arising in erect position at the extremity of almost every shoot, which are very conspicuous at a considerable distance.

The second species, Scarlet Horse-Chestnut,

obtain twelve or fifteen feet stature, the branches moderately spreading, the flowers are of a red or scarlet colour, grow in spikes like those of the common sort, though not so large, but make a pretty appearance.

The leaves of both species are digitate or fingered, and very large; those of the common sort have seven long, broad, obtuse lobes; but the scarlet kind have rarely more than six, which in both sorts unite at their base, where they are attached to the foot-stalk, and expand like the fingers of a hand.

The flowers of the Common Horse-Chestnut appear in May and beginning of June, and those of the other in July.

The nuts of the common sort ripen plentifully in autumn, but those of the second do not always ripen perfectly in England: they are useful only for propagation; deer and swine will eat them greedily.

Abroad the nuts of the common sort are made into meal and given to horses, hence they derive the name.

The Common Horse-Chestnut has been long cultivated for purposes of ornament in extensive gardens, lawns, parks, &c. It was formerly much employed to form avenues and shady walks, but the mode of planting these trees in long continued lines or ranges, as was the former practice, affords no variety; nor do the trees appear to advantage in that order of arrangement. They have a fine effect placed singly and considerably detached, their natural form of growth adapts them for this, and may be employed in extensive places, to form detached clumps of two, three, four, or more trees together, and in some places grouped with others of similar growth, placing them in different forms of arrangement to effect variety.

In large ornamental plantations, some trees may be interspersed to advantage toward the front.

If required to adorn avenues, it should always be in assemblage with other trees, such as the lime, greater maple, common or Spanish chestnut, and other formal trees with large foliage.

For purposes of shade the trees are properly adapted, but not as thickets, because when they stand close they do not retain their leaves.

The timber of these trees being of no value, they do not merit culture on that consideration.

The Scarlet Horse-Chestnut merits a place in

in all ornamental plantations, where they should occupy spaces toward the front, and their scarlet flowers will effect an agreeable variety.

Propagation.

The common sort may be raised plentifully by planting the nuts, and the best time is in February, as if planted in autumn many may rot in winter; but until the season of planting arrive, it is necessary to preserve them in sand, to prevent mouldiness.

The nuts may either be bedded in, or planted in drills, two or three inches deep; the plants will appear in April or beginning of May; by the end of summer they will be eight, ten, or twelve inches high, and in autumn or spring following they may be transplanted in the nursery way in rows thirty inches distant, and half that distance from one another in each row.

In this nursery let them remain four or five years, when, as the plants are of very quick growth, they will be six or seven feet high, and may then be employed in plantations.

The two varieties with striped leaves may be increased by layers, and by budding or grafting them upon stocks of the common sort.

The scarlet sort may also be propagated by planting the nuts; those of American growth are generally the most perfectly ripened; however, as the nuts are sometimes difficult to be procured, the trees may likewise be readily increased by budding or grafting them upon stocks of the common horse-chestnut.

If it is however intended to raise them from nuts, the aid of a hot-bed will greatly facilitate their vegetation.

Plant them in pots in the spring, and plunge them in the hot-bed. When the plants appear, indulge them with the free air daily, and in a month remove the pots to the full air to remain till October, then place them to have occasional shelter from frost, and in spring transplant them in rows in the nursery.

ÆTHUSA, Fool's Parsley, or Lesser Hemlock.

As this is a common weed of noxious quality, we only mention it by way of caution, the leaves of which, while young, are so like those of common parsley, as not to be distinguished without some attention, and has often been inadvertently gathered with it, to the fatal experience of many.

To remove all suspicion, it is most eligible

to cultivate only the curled leaved parsley, which may with facility be distinguished from the weed in question.

AGAVE. Great American Aloe, or Agave.

This is the genus of aloes, of which the common opinion prevails that the plants do not flower until they are a hundred years old. They are herbaceous perennials of the succulent tribe, exotics of the temperature of the green house and stove departments, and retained by the curious as plants of singularity.

The *Agave* belong to the class and order *Hexandria Monogynia*.

Characters] CALIX none. COROLLA, one large funnel-shaped petal, divided at the brim into six segments. STAMINA, six long filaments with narrow antheræ. PISTILLUM, an oblong germen placed below the corolla, supporting a long style, having a three-cornered stigma. PERICARPIUM, the germen becomes an oblong triangular capsule of three cells, pregnant with compressed seeds.

There are eight or ten species; those of most note are,

¹AGAVE *Americana*.

Common great American Agave.] Agave with large widely indented leaves, all the denticles ending in a sharp spine, and branching flower stem.

Varieties.] Common American Agave with gold striped leaves.—Common American Agave with silver striped leaves.

²AGAVE *Virginiana*.

Great Virginian Agave.] Agave with large widely indented spinous leaves, and simple flower stem.

³AGAVE *Vera Cruz*.

Veracruzian broad-leaved Agave.] Agave with large closely indented leaves, all the denticles armed with black spines.

⁴AGAVE *Rigida*.

Stiff narrow-leaved Veracruzian Agave.] Agave with very narrow stiff entire leaves, terminated by a black spine.

⁵AGAVE *Vivipara*.

Viviparous, or Childing Agave.] Agave with reflexed slightly indented leaves, and with young plants succeeding the flowers.

⁶AGAVE *Fœtida*.

Stinking Childing Agave.] Agave with narrow stiff entire leaves, and with young plants succeeding the flowers.

All the species are natives of America, the first three grow freely here, indulged with the shelter of any common green-house in

in winter, but the other three sorts succeed best in a moderate stove during that season.

These plants in general are herbaceous, perennial, succulent, and evergreen, and of large and singular growth, consisting entirely of very long, erect, thick, fleshy leaves, the same leaves continuing many years, and all the species have this singularity, they never flower but once, which is rarely till they are upward of fifty, and frequently sixty, or near an hundred years old, when the flower stem is of such amazing rapidity of growth, as in one season to attain the height of twenty or thirty feet, supporting an enormous pyramid of flowers, continuing several months; after which succeeds the dissolution of the whole plant; stem, leaves, and root totally perish.

The roots of all the sorts are thick, fleshy, and fibrous, sending forth innumerable small fibres every way.

The plants are acaulis, having no stalk or trunk to elevate the leaves, they rising immediately from the crown of the root in a vast cluster, and attain considerable length and substance, grow erect, and embrace one another at the base; those of the centre are closely enveloped from bottom to top, which, in different species, obtain different heights, from eighteen inches to six or eight feet, and from one to six or eight inches in breadth, and three or four thick, decreasing gradually in substance to the extremity, where they terminate in a thorny point; and from between the centre leaves is produced the flower stem, which rises from fifteen to twenty-five feet high; in most species branching out on every side pyramidally, and all the numerous shoots closely adorned with considerable clusters of yellowish flowers growing erect, the whole assuming a beautiful pyramidal form, of a singularly grand appearance, continuing three or four months, and when the flowers fade, they in some are succeeded by seed, in others, instead of seed, by young plants, in the place of proper seed vessels.

The seed however never comes to maturity in England, but the young plants attain it fully.

The first, second, and third species, and varieties, obtain considerably the largest growth, their leaves often growing five or six feet high and upward, particularly the two former; the second is distinguishable from the first by the leaves being of a paler green, and much narrower upward; and the third from both these by the leaves being broad, thinner, and the

indentings on the edges more frequent and slight, and the armature or spines very black.

The *Common great Agave* and *Agave Virginiana*, have flowered frequently in many parts of England; the stem of the former always branches pyramidally, and that of the latter is simple, and supports its flowers entirely at its summit in a vast cluster.

The two varieties of the *Common Agave* with striped leaves are plants of singular beauty, and merit particular attention.

The fourth species, *Agave Rigida*, is of moderate growth, the leaves rarely exceed an inch and half in breadth, and eighteen or twenty in length, they are of stiff texture, the outward ones spreading horizontally.

The fifth and sixth sorts, *Agave Vivipara* and *Fœtida*, hath great singularity, that in the former, though the plant itself rarely exceeds eighteen inches or two feet, it produces a flower stem ten or twelve high, and in the latter, though it is seldom more than a yard high, the flower stem often attains six or seven times that height; and what is still as remarkable, the flowers, instead of being succeeded by proper seed vessels, are productive of young plants, hence they derive the name Childing Aloe.

Both these have flowered in England, and produced numbers of young plants on their flower stems as above, which being planted, readily grow.

Of the flowering of all these plants, it is the common opinion that they do not effect it until they attain the age of a century; the time of their flowering however is not limited, but depends upon the growth of the plant, which is particularly affected by heat and cold, for as the flower stem being produced from the centre of the leaves, and these closely embrace one another, it is evident, that until they are fully expanded, the bud of the stem is not at liberty to advance; and in this climate, by reason of cold, the growth of the plants being remarkably slow, it is often near an hundred years before they effect that expansion; when the stem however begins to appear and advance, it makes surprising progress, as in the space of three or four months it acquires its full stature.

Propagation and Culture.

The first and second species and varieties are productive of abundant off-sets or suckers from their base, by which they may be propagated with great facility. These suckers may be taken off any time in summer, and planted

planted singly in small pots of light sandy earth; give a little water, and they will take root freely without trouble.

The third and fourth being sparingly productive of suckers, they, in default of which, may be increased by planting pieces of their large roots in pots, and plunge them in a moderate hot-bed, they will put forth fibres in the earth, and shoots above, and form proper plants in three months. The fifth and sixth sorts are as sparing of suckers as the two former, but in lieu of which they produce young plants on their lofty flower stems; but until they flower, those cannot be obtained, their propagation therefore may also be tried by pieces of the root and leaves as above.

It is to be remarked, that in respect to soil, all the sorts require a dry light sandy earth, because the plants themselves being very succulent and humid, a soil that retained moisture would rot the roots in winter.

With respect to their general culture, they must always be retained in pots or tubs. The first, second, and third sorts, and varieties, succeed in the full air from May until the end of October, when they should be placed in the green-house, but the fourth, fifth, and sixth sorts are of the most prosperous growth when they have the constant protection of a stove. And it is to be particularly observed, that as all these plants are extremely succulent and replete with moisture, they require very little water in winter, particularly those in the green-house; but in hot dry weather in summer should have moderate waterings twice a week.

According as the plants advance in growth they should be indulged with larger pots, but never any too large, except the great sorts which, when they attain a large size, should be shifted into tubs for the convenience of moving them. See SHIFTING PLANTS.

It is necessary to shift all the sorts once in two years at least into fresh earth, see SHIFTING PLANTS.

When the plants make an effort for flowering, it is discoverable by the centre leaves expanding, and the bud of the future stem appearing, which, if it do not advance freely, it may be forwarded by artificial heat; a deep trench or pit filled with hot dung or tanner's bark, or a mixture of both, raising it two or three feet; into which plunge the pot or tub, containing the plant, and supply it with water, observing if the plant is at this time in any place of shelter, way must be made upward,

if necessary, for the stem to advance; and if the weather is cold, it must not be exposed, so that a temporary awning should be erected to shield it occasionally.

As some of these plants acquire a very considerable size, and take up much room in a green-house, and being troublesome to move, a few should only be cultivated to grow large.

Sometimes the great sorts grow so very large and weighty before they arrive at a flowering state, that the tubs containing them are obliged to be fixed upon strong frames with low wheels, for the convenience of moving them out and in to the green-house.

The following are the other less common species of Agave.

¹AGAVE *Karrata*.] Karrata Agave with long erect dark green leaves, edged with brown, and slightly sawed.

²AGAVE *Tuberosa*.] Tuberous rooted Agave with long narrow indented spinous edged leaves.

³AGAVE *Serrata*.] Serrated green Agave.

AGERATUM, Bastard-Hemp Agrimony.

The plants are herbaceous, there are three or four species, one of which only claim esteem, which is a hardy perennial, that attains three or four feet stature, terminated by snowy heads of flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] The flower is compound. CALIX, the common cup is oblong and scaly. COROLLA, composed of several hermaphrodite tubular florets. STAMINA, five filaments with the antheræ united. PISTILLUM, an oblong germen, slender style, and two small stigma. PERICARPIUM none, each germen becomes a seed crowned by a minute five parted cup, placed in a naked receptacle.

The species that merit attention is,

AGERATUM *Altissimum*.

Tall Canadian Ageratum.] Ageratum with a tall smooth stalk, oval heart-formed rough leaves, and alternate flower branches.

This plant is perennial in root, but the stalks rise annually in spring, flower in the end of summer, and perish in autumn.

The roots are fibrous and spreading.

The stalk rises four or five feet high, furnished upward with many side-branches, decorated with leaves, and terminated by large tufts of white flowers, appearing about Michaelmas, and continue three weeks, and are sometimes succeeded by ripe seeds.

It

It is proper furniture for such compartments where tall plants are required.

The propagation of this plant is by seed, and by parting the roots; by the latter it encreases considerably, and may be performed in autumn, or early in spring.

AGGREGATUS Flos. An Aggregate Flower.] This consists of a number of smaller flowers or florets, collected into one head by means of some part common to the whole, such as one common receptacle and calix or cup; that in the proper aggregate flower each separate floret or fructification are erected on a short foot stalk, standing on the receptacle or base, which is extended in breadth for that purpose; and in many aggregate flowers, the florets, besides the common calix, are each furnished with a proper cup.

From the different structures, disposition, and other circumstances of these common parts, the receptacle and calix arises a seven-fold division of aggregate flowers, viz.

¹The **AGGREGATE** Flower, properly so called; such as scabious, globularia, cephalanthus, thrift, &c.

²The **COMPOUND** Flower; such as sunflower, marigold, African marigold, milfoil, eupatorium, &c. See **COMPOSITUS Flos.**

³The **UMBELLATE** Flower; such as fennel or fennel-giant, bupleurum or hare's-ear, eryngium, parsley, angelica, lovage, &c. See **UMBELLATÆ.**

⁴The **CYMOSE** Flower; such as honeysuckle, gelder-rose, laurustinus, elder, &c. See **CYMA.**

⁵The **AMENTACEOUS** Flower or Catkin; such as that of the pine-tree, poplar, beech, birch, walnut, cypress, hazel, willow, &c. See **AMENTACEOUS FLOWER.**

⁶The **GLUMOSE** Flower; such as that of wheat, oats, reed, Turkey wheat, and all the grasses. See **GLUMOSE FLOWERS.**

⁷The **SPADICEOUS** Flower, protruding their heads of flowers from a spatha or sheath; such as the narcissus, amaryllis, colchicum, snow drop, asphodel lily, blood flower, sea-daffodil or pancratium, garlick, onion, leek, &c. See **SPADICEUS, SPADIX, &c.**

For a particular description of each of the above species of aggregate flowers, see each in its proper place.

AGRIMONIA, Agrimony.

This genus furnishes five herbaceous perennials, that obtain from eighteen inches to three feet stature; two or three proper

for ornament, the others for medical purposes.

Class and order, *Dodecandria Digynia.*

Characters.] **CALIX**, one leaved, cut into five acute parts, and sits on the germen. **COROLLA**, five plane petals inserted into the calix. **STAMINA**, twelve filaments with double antheræ. **PISTILLUM**, a germen placed under the flower, supporting a double style. **PERICARPIUM**, the germen becomes two roundish seeds attached to the calix.

The species are,

¹**AGRIMONIA Eupotaria.**

Common officinal Agrimony.] Agrimony with winged cauline leaves, having small sawed lobes and rough seed.

²**AGRIMONIA Repens.**

Creeping-rooted Eastern Agrimony] Agrimony with thick creeping roots, winged, cauline leaves, having narrow lobes, short spikes, and hairy seeds.

³**AGRIMONIA Odorata.**

Odoriferous Agrimony.] Tallest Agrimony with pinnated cauline leaves, having many oblong sharply-sawed lobes.

⁴**AGRIMONIA Agrimonoides.**

Agrimonoides, or Three-leaved Agrimony.] Agrimony with cauline leaves, having three lobes, and smooth seed.

The plants have fibrous roots, which are perennial, from which arise several branching leafy stalks annually in spring, and decay in autumn, after they have flowered and perfected seed.

The first sort grows wild in woods and uncultivated shady places, but is retained sometimes in gardens as a medicinal herb.

The stalks of the second sort rise near two feet high; the third, double that height; and the fourth, near a yard; and the stalks of each sort are branching, and closely adorned with small winged leaves, and terminated by spikes of flowers. The third sort is in much esteem for the odoriferous property of its leaves and flowers. All the three species may be retained as furniture for common borders, and such places where many plants of easy culture are required, as they succeed in any exposure, and will effect an agreeable diversity in assemblage.

The propagation of all the sorts is effected by seed, and by parting the roots in autumn, or early in spring, but as they multiply exceedingly by roots, that is the most expeditious method.

AGROS-

A G R

AGROSTEMMA, Wild Lychnis, or
Campion, Rose Campion.

The plants are herbaceous perennials, there are three or four species, one of which produce beautiful garden flowers, the others have no merit.

Class and order, *Decandria Pentagynia*, ten stamina, five styles.

Characters.] **CALIX**, monophyllous, tubular, five-parted at the brim, and permanent. **COROLLA**, five broad expanded petals. **STAMINA**, ten filaments, five of which are inserted alternately into the base of the petals. **PISTILLUM**, an oval germen, five styles, having single stigma. **PERICARPIUM**, an oval capsule of one cell, having five divisions pregnant with seeds.

The species and its varieties are,

AGROSTEMMA Coronaria.

Coronated Agrostemma, or Common Rose Campion.] Agrostemma with ovate, spear-shaped, woolly leaves, and coronated undivided petals.

Varieties.] Single Rose Campion with pale red flowers.—Single Rose Campion with deep red flowers.—Single Rose Campion with white flowers.—Single Rose Campion with white and red flowers.—Double Rose Campion with a large crimson flower.

All the above varieties are extremely hardy fibrous-rooted perennials, that succeed in any common soil of a garden, and are of easy culture.

They grow eighteen inches or two feet high, the leaves are hoary and whitish, and rise from the root in a great tuft, and remain all the year; and from the centre is produced the flower-stem annually in the spring, which rarely exceeds two feet stature, divides into many branches, all of which are terminated by the flowers in July and August, which, in the single kinds, are succeeded by numerous seeds, but the double sort produce none.

The flower of the common single kinds have only five petals, but those of the double sort are numerous, even to the exclusion of the parts of fructification, so that they consequently produce no seed.

The Double Rose Campion is a most elegant flower, and the single kinds, though of inferior beauty, form a pretty variety.

The single kinds rise plentifully from seed sown in a bed of common earth, in spring or autumn; when the plants are two or three inches high, prick them into another bed or border, six inches distance, giving occasional watering; and in autumn or spring following

A I R

transplant them into the borders for flowering, which they will effect the ensuing summer.

As the old plants are apt to grow straggling, it is proper to raise a supply of young ones every year.

They also rise plentifully from scattered seeds.

The double sort, producing no seed, can only be propagated by parting the roots, they generally afford plenty of off-sets, which should be parted in autumn as soon as the flower is past; plant them in a bed of common earth, six inches a-part, to remain until spring; then transplant them where they are to flower.

Some plants may with propriety be cultivated in pots, to adorn court-yards.

AIR. In vegetation, air, heat, and water, are its principal agents: Air abounds with vegetable substances, necessary to the growth and welfare of all seeds and plants; and it has been proved by numerous experiments, that without a certain portion of Air, no seeds can germinate, nor plants grow freely, nor seeds and fruits attain due perfection.

Air enters into the bowels of the earth to a certain depth; thence into the pores of seeds, roots, and veins of the very trees and herbs, carrying along with it those vegetable substances contained either in itself, or lodged in the earth; and even enters through the bark and body of the trees, and materially effects their branches, leaves, flowers, and fruit.

The humidity of the Air alone often makes many sorts of seeds rise, and roots and plants shoot, that are exposed to it; seeds and plants too are often observed to vegetate in water, without the intervention of earth; but either of these without Air is insufficient. Many succulent plants, by the assistance of Air only, will retain their growing quality several months; and some sorts of aloes will live without earth and water some years, if secured from frost, particularly exemplified in the *Aloe Barbadosis*: and the branches of some sorts of *Sedum* and *Sempervivum*, being cut off in summer and exposed to the Air, have been observed to emit roots without the aid of earth and water, and live several months; the *Sempervivum Arboreum* particularly furnish examples.

Air in a certain degree is most necessary to preserve the vegetative faculty of seeds, previous to their being committed to the earth;

as for example, if seeds are put into phials or bottles, close stopped, and sealed down, and retained therein several months, they, for want of air to nourish and preserve health in the germ, lose their germinating quality.

Thus, for want of a due portion of Air, seeds which are buried to too great a depth in the earth, either thrive but indifferently, or do not grow at all.

They frequently preserve, however, their germinating virtue for many years in the bowels of the earth; and it is not unusual upon a piece of ground being newly dug to a considerable depth, to observe it soon after covered with plants, which had not been seen there in the memory of man. How the vegetative property is so long maintained in seeds so deeply immersed in the ground, is hard to account for; but certain it is, that there have been instances of seeds having been buried several feet deep upwards of thirty years, and when turned up again to the air, they germinated like new seeds; and soil that have been taken out of the bottom of wells, vaults, and sewers, and spread in the Air, have produced many unknown weeds or plants.

It is observable of trees and plants, whose roots are planted a considerable depth, that being out of the reach of the proper influence of Air, sun, and showers, they do not prosper.

The same is also very obvious in plants growing in garden-frames under glasses, and in green-houses and stoves: if they are kept too close, they do not prosper; and if deprived of a proper current of Air, they draw up feeble, become meagre, dwindle, and die before their usual time. Great attention ought therefore to be at all opportunities observed, to admit the fresh Air to plants retained in those departments. Common hardy plants, that require only protection of frames from frost in winter, should be fully exposed every mild day, by taking off the covers: those of tender quality, that need artificial heat, and continual shelter of frames and glasses, such as early cucumbers, melons, and tender annuals, &c. although they are unable to endure the full Air till June, should be indulged with a due portion thereof every day, even in frosty weather, if there is heat in the beds; which is effected by raising on props one end of the lights, from half an inch to three in height, according to the temperature of the beds, and that of the outward Air. Green-house plants,

during the winter season, should be allowed free air every mild calm day, by opening the windows less or more: and stove plants should also have the indulgence of fresh Air in mild, sunny, calm days; even occasionally in winter, when the sun shines warmly.

Plants in general prosper best where they enjoy the full Air in as great a degree as their respective temperaments will admit. All hardy kitchen-garden vegetables attain the greatest perfection in a free exposure: as for example, if peas, beans, cabbages, &c. are planted under spreading trees, or in any close or shady place where they are deprived of a proper current of Air, they draw up weak without taking the proper consistence, and do not attain half the perfection, neither in quantity nor quality, as those that are more exposed.

Fruit likewise that are produced in orchards where the trees and branches are so crowded as to exclude the proper circulation of Air, never attain due perfection, neither in size, colour, nor relish.

AJUGA, Bugula, or Bugle.

The plants are herbaceous perennials, of the ornamental kind, of stature from six to twelve inches, adorned at top with many flowers collected into whorled spikes.

Class and order, *Didynamia Gymnospermia*.

Characters] CALIX is one-leaved, cut into five segments. COROLLA, monopetalous, tubular, and labiated, the tube long and incurved, the upper lip short and bifid, the under one large, and three-parted. STAMINA, two short, two long filaments, and double antheræ. PISTILLUM, four germina elevating one style, having two stigma. PERICARPIMUM none, four seeds lodged in the calix.

There are seven or eight species, those that demand notice are,

¹AJUGA *Reptans*.

Creeping common blue Bugle] Bugle with obovate crenated leaves, half embracing the stalk, creeping side shoots emitting roots, and blue flowers.

Varieties.] Common Bugle with purple flowers.—Common Bugle with white flowers.

²AJUGA *Decumbens*.

Declinated Alpine Bugle.] Bugle with oblong oval leaves, reclining stalks, and the whorls of flowers remote.

³AJUGA *Pyramidalis*.

Pyramidal blue Bugle.] Bugle with a simple stalk, oval bluntly indented leaves, and close pyramidal blue spike.

Varieties.]

Varieties.] Pyramidal red Bugle.—Pyramidal white Bugle.

¹*AJUGA Genevensis.*

Geneva Bugle.] Bugle with oblong woolly leaves, hairy calix, and flesh coloured flowers.

Variety.] Geneva white Bugle.

²*AJUGA Orientalis.*

Eastern inverted white Bugle.] Bugle with oval, indented, hairy, close fitting leaves, and inverted white flowers.

Variety.] Eastern inverted blue Bugle.

They are all of humble growth, the roots fibrous and creeping; the stalks rise from six to twelve inches high, emitting trailing, rooting shoots, and decorated with small, simple, ovate leaves below, and many small flowers upward, collected into whirls round the stalk, in some forming a close spike.

They flower early in summer, and yield plenty of seed.

The *Common Bugle* grows naturally in woods in England, the next three on the Continent, and the fifth in the Levant.

The former four succeed in any common shady border, the fifth should be potted and shielded from frost.

The propagation of all the sorts is by off-sets, or side shoots, which root in the earth, and may be separated at any time, or may be raised from seed.

ALATERNUS. See RHAMNUS.

ALBUCA, Bastard Star of Bethlehem.

This genus furnishes two species of bulbous-rooted herbaceous perennials, of the flowery tribe, whose flower-stalks rise from eight to fifteen inches high.

Class and order, *Hexandria Monogynia.*

Characters.] CALIX none. COROLLA, six oblong oval petals, three of which expand, and three standing inward and connected. STAMINA, six long trigonous filaments, three of which are alternately castrated, the others are crowned with moveable antheræ. PISTILLUM, an oblong triangular germen and style, surmounted by a conic triangular stigma. PERICARPIUM, the germen ripens to a three-cornered capsule of three cells, containing many small seeds.

The species are,

¹*ALBUCA Major.*] Greatest Canadian Albuca, with spear-shaped leaves.

²*ALBUCA Minor.*] Least African Albuca, with narrow awl-shaped leaves.

Both these species have moderately large bulbous roots, from which the leaves and

flower-stem rise annually; the leaves rise first, which are long and narrow, and the stem rises in the centre of them, ornamented with yellowish flowers of the liliaceous tribe, appearing towards autumn, but rarely ripen seeds in England.

In the first species the stem rises twelve or fifteen inches high, decorated with many drooping flowers, forming a loose spike.

The second grow eight or ten inches high, surmounted by a few erect flowers, forming a sort of corymbus.

Both the species require protection from frost, so the roots should be retained always in pots, and placed in a frame in winter, to have occasional shelter.

Their propagation is by off-sets from the roots, when the flower is past in summer.

ALCEA, Hollyhock, or Rose Mallow.

This genus furnishes many curious varieties of hardy herbaceous perennials, of the flowery race, whose flower-stem obtains a lofty stature, adorned with numerous large and elegant rose-like flowers.

Class and order, *Monadelphia Polyandria.*

Characters.] CALIX, two monophyllous cups, the inner slightly five-parted, the outer six, and expands. COROLLA, five large expanded petals. STAMINA, numerous filaments united below, with the styles like a column, and kidney-shaped antheræ. PISTILLUM, a round germen, a short style, many-parted at top, having as many stigma. PERICARPIUM, the germen ripens to a round, depressed, jointed capsule of many cells, each containing one seed.

There are only two distinct species, but of which are many beautiful varieties, of various colours, such as whites, all the tints of red and purple, and almost every degree of yellow, and of each variety there are single and double flowers.

The species and principal varieties are,

¹*ALCEA Rosea.*

Common Hollyhock, or Rose Mallow.] Hollyhock with rounded and angularly sinuated leaves.

Varieties.] Hollyhock with white flowers.—Cream coloured Hollyhock.—Flesh coloured Hollyhock.—Red Hollyhock.—Flaming red Hollyhock.—Blackish red Hollyhock.—Purple Hollyhock.—Pale yellow Hollyhock.—Deep yellow Hollyhock.—Variegated Hollyhock.

²*ALCEA Ficifolia.*

Fig-leaved or Palmated Hollyhock.] Hollyhock with palmated or hand-shaped leaves.

Varieties.] Several of different colours, as those of the former.

Both these species and respective varieties are hardy perennials, that prosper in any common soil and situation; they are perennial in root, but the stalks are annual, they rising in spring attain six or eight feet stature, flower in July and August, perfect seeds in September, and soon after perish.

The roots are fibrous, white, long, and spreading, but not furnished with many small fibres.

The leaves are both radical and elevated on the stem, simple, and from three to eight or nine inches broad, the radical or root-leaves rise in a great cluster.

The stem rises between the radical leaves, immediately from the root; is round, erect, and grows two or three yards high, ornamented on every side with leaves and flowers, forming a spike from three to five feet in length, the flowers making their first appearance when the stalk is about a yard high, and as that advances, furnishes a daily supply of more new flowers, for six or eight weeks, which make a fine appearance.

All the varieties, both single and double, afford plenty of seed for propagation.

The flowers in their single state have but five petals, but those of the doubles are numerous, and the flower equal in bigness to the largest double Provence rose; in some, the outer petals are large and spreading, those within small, and form a globular body in the middle.

There are different degrees of doubleness, with respect to the quantity and disposition of the petals, but those fully double have singular elegance.

Use in Gardens, Culture, &c.

All the varieties of these plants are very ornamental to the pleasure ground, although they are often disregarded by the incurious, but we know very few herbaceous plants that equal them in beauty as garden flowers for ornament, especially when their tall stems are duly supported and trained in erect position.

The propagation of all the varieties is easily effected by seeds sown in a bed of common earth, in March or April; the plants appear in a few weeks, and will be fit to transplant in autumn.

The first year the plants produce only ra-

dical or root-leaves; the second, they shoot up their stalks and flower.

In sowing these seeds, it is eligible, as they are pretty large, to draw flat shallow drills for their reception, half an inch deep, and six asunder; sow the seed thin and regular, rake the earth over them, and trim the surface smooth: the plants will appear in a month; and in July, when they will have several leaves, transplant them into a nursery-bed, nine inches distance, and give occasional waterings for a fortnight.

In October, November, or spring following, transplant them into the borders and other open compartments of the pleasure ground, shrubbery, &c.

We observed formerly that the plants are perennial in root, but we would be understood, that although the same individual continues many years, it never flowers so strong, nor are the flowers so large, double, and lively in colour as the first and second year. Persons that are curious should therefore raise a supply annually from seed.

Always, if possible, have regard to procure seed saved from the best double flowers.

ALCHEMILLA, Ladies-Mantle.

This genus retains several species of hardy herbaceous perennials, some of which merit culture for the singularity of their leaves, which are curiously scalloped, waved, and plaited.

Class and order, Tetrandria Monogynia.

Characters.] *CALIX* is monophyllous, eight-parted, spreading at the brim, and permanent. *COROLLA* none. *STAMINA*, four filaments attached to the brim of the calix, having yellow antheræ. *PISTILLUM*, an oval germen, long style, and globular stigma, and the germen ripens to a single seed.

The species are,

¹*ALCHEMILLA Vulgaris.*

Common Ladies-Mantle.] *Alchemilla* with roundish, lobated, sawed leaves.

²*ALCHEMILLA Minor.*

Least Ladies-Mantle.] *Alchemilla* with roundish, lobated, plaited, sharply sawed, silvery leaves.

³*ALCHEMILLA Pentaphylla.*

Five-leaved fimbriated Alchemilla.] *Alchemilla* with five-lobed leaves, the lobes finely cut like fringes.

⁴*ALCHEMILLA Alpina.*

Alpine digitate Alchemilla.] *Alchemilla* with digitate or fingered, hoary, sawed leaves.

All four species are hardy, fibrous-rooted, herbaceous perennials, that prosper in any common

common soil and exposure, have perennial roots, but the leaves and stalks are renewed annually.

The leaves are the principal merit of the plants, for purposes of ornament in gardens; they rise immediately from the root on long foot-stalks, those of the first and second are roundish, broad, and scalloped into several lobes, which are waved and plaited, hence the plants derive the name Ladies-Mantle.

The flower-stem rises between the leaves, ten or fifteen inches high, very branching, having all the branches terminated by clusters of flowers, which being apetalous, make no figure.

The *Common Alchemilla*, second and third sorts, grow wild in meadows and mountainous places, and are admitted in gardens for variety.

The propagation of all the species is by parting the roots, and by seed sown in a shady border.

The *Alchemilla Vulgaris* is a medicinal plant.

ALETRIS, Guinea Aloe, &c.

The plants of this genus are herbaceous, succulent evergreens, of the aloecaceous tribe, natives of hot climates, and retained here in stoves for curiosity.

Class and order, *Hexandria Monogynia*, six stamina, one style.

Characters.] CALIX none. COROLLA, one oblong oval liliaceous petal, six-parted at the brim. STAMINA, six long filaments inserted in the corolla. PISTILLUM, an oval germen, awl-shaped style, and trifid stigma. PERICARPIUM, a trigonous capsule of three cells, and angular seeds.

There are five or six species; those of note are,

¹ALETRIS *Hyacinthoides*.

Hyacinth-flowered Guinea Aletris.] Aletris without stalk, spear-shaped fleshy leaves, and flowers proceeding by pairs.

²ALETRIS *Zeylanica*.

Ceylon dwarf Aletris.] Aletris without stalk, and spear-shaped, plane, erect leaves.

³ALETRIS *Capensis*.

Cape undulate Aletris.] Aletris without stalk, spear-shaped undulate leaves, and oval spike of nodding flowers.

⁴ALETRIS *Fragrans*.

Fragrant stalky Aletris.] Aletris with an erect stalk, elevating a head of spear-shaped leaves, embracing it with their base.

These plants have the appellation of aloes

among gardeners, derived from their similarity of growth, particularly the two first, i. e. Guinea Aloe, and Ceylon Aloe.

The roots of all these plants are thick, fleshy, fibrous, and creeping.

The first three sorts are acaulous plants, i. e. having no stem nor foot-stalk to elevate the leaves, they rising immediately from the root, and without any visible foot-stalk of their own; are narrow, stiff, fleshy, and grow from six to eighteen inches in length, and the flower-stem rises between the leaves, also from the root, attaining the same height, decorated with many bright white liliaceous flowers, of the hyacinth form, arranged in a sort of spike.

In the former, the leaves and stem rise a foot and half high, and produce many flowers; the second rise but six or eight inches, and rarely flower here; and the third attain a foot in height, and flowers annually.

The fourth sort is furnished with an erect, succulent, jointed stalk, that obtains three or four feet stature, elevating a cluster or head of thin reflexed leaves at top, and from their centre proceeds the flower-stem, arising two feet high, branching each way, and beautifully decorated with numerous fragrant white flowers.

All these plants, being exotics of delicate temperature, must be constantly kept in pots, and retained always in the stove.

The propagation of all the sorts is by offsets or suckers, which in the two first arise plentifully from the root, in the fourth from the sides of the stem, and may be taken off in summer, planted in small pots of sandy earth, and plunged in the bark-bed.

ALLEYS, in Gardening, Alleys are narrow paths between beds, borders, and other garden compartments, designed principally for the convenience of going between such compartments, to do what is necessary to the plants, and gather their produce: Alleys are also sometimes intended both for use and ornament in flower gardens.

In kitchen gardens, where a border is carried round next the main walks, it should be divided from the quarters by a two feet Alley, for the convenience of carrying in dung and water; and the large quarters should also be divided by one or two cross Alleys for the same purpose.

The proper width of Alleys between beds, is from one to two feet; as, for example, Alleys between asparagus beds should be two feet wide; those between strawberries, a foot and

and half ; and between beds of aromatic herbs, fifteen inches : but between beds of onions, leeks, carrots, parsnips, lettuce, endive, and other small crops, ten or twelve inch wide Alleys is sufficient ; the same also between beds of seedling cabbage, favoys, and cellery, for the convenience of going in to draw the plants for transplantation.

In flower gardens, Alleys are often designed both for use and ornament. Between beds of tulips, hyacinths, ranunculas, anemonies, and other flowers that are bedded, the Alleys should be eighteen inches wide ; and to have them ornamental, the beds should be edged with box, and the Alleys filled with the best high-coloured fine gravel ; or in default of that, with sand or shells.

ALLIUM, Garlick, Onion, and Leek, &c.

By the laws of Linnæan botany, the onion and leek are retained as species of Allium, or garlick, and we shall treat of them accordingly ; but, for distinction sake, shall first proceed with the garlick kind ; then with that of the onion, *Allium Cepa* ; next with the leek, *Allium Porrum*.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, is a spatha serving as a general cup, protruding many flowers. COROLLA, each is composed of six oblong erect petals. STAMINA, six subulated filaments, elevating as many oblong antheræ. PISTILLUM, a trigonous germen, simple style and stigma. PERICARPIUM, a triangular capsule of three valves, and cells pregnant with roundish seeds.

Of the garlick kind there are upwards of thirty species, but many of them being plants of no merit, we shall only notice those proper for æconomical purposes, and for ornament in gardens.

The species are,

¹ALLIUM *Sativum*.

Common officinal Garlick.] Allium with compound bulbs, and plane cauline leaves.

²ALLIUM *Scorodoprasum*.

The Rocambole.] Allium with plane, indented, cauline leaves, two edged vagina, and stalk terminated by a head of bulbs.

The above two are officinal plants.—The following are of the flowery kind.

³ALLIUM *Moly*.

Common yellow Moly] Allium with broad, spear-shaped, radical leaves, a naked and nearly cylindrical stalk, and flat yellow umbels.

⁴ALLIUM *Subhirsutum*.

Hairy white Moly of Dioscorides.] Allium

with plane cauline leaves, hairy below, awl-shaped stamina, and white umbels.

⁵ALLIUM *Sphærocephalon*.

Spherical headed purple Moly.] Allium with a taper stalk, half-taper cauline leaves, long three-pointed stamina, and round purple umbels.

⁶ALLIUM *Roseum*.

Rose-coloured Montpelier Garlick.] Allium with linear radical leaves, naked stalk, short pedicles, oval petals, short stamina, and rose-coloured umbels.

⁷ALLIUM *Flavum*.

Straw-coloured pendulous Moly.] Allium with taper cauline leaves, oval petals, long stamina, and pendulous pale yellow flowers.

⁸ALLIUM *Magicum*.

Great purple Moly.] Allium with plane cauline leaves, simple stamina, and bulbs growing in the branches of the umbel.

⁹ALLIUM *Victoralis*.

Victoralis, or Elliptical Garlick.] Allium with elliptical, plane, cauline leaves, spear-shaped stamina longer than the corolla, and a round umbel.

All these species are of the bulbous rooted tribe ; some have very large bulbs, others not bigger than peas : they are perennial in root, but annual in leaf and stalk.

They are all extremely hardy, will prosper in almost any exposure and soil of a garden, and multiply exceedingly.

Most of the sorts have a strong scent like the common garlick.

The first sort, *Common Garlick*, hath a large, round, white, bulbous root, composed of many smaller bulbs called cloves, each of which being planted, grow, and in one season attain the size and structure of the parent bulb ; the leaves are cauline, or form a kind of stalk, which, in this species, seldom spindles, except when the same roots remain in the ground two or three years, when they run up and bear a flower, and small bulbs at top.

This sort merits culture in every garden for its roots for kitchen and other domestic uses.

The *Rocambole* hath very small bulbs, which grow in clusters ; the stalk generally spindles two or three feet high, bearing many small bulbs at its summit, and these are commonly used instead of the root.

With respect to the flowery kinds, the flower-stems rise immediately from the root, grow erect, and attain different heights, from twelve to thirty inches ; in some the leaves are radical, in others cauline, i. e. elevated with

with the stalk; some are broad like those of a tulip, others long and narrow like a daffodil, and some taper and rush-like; and in all the sorts the stems are terminated by a spatha or sheath, from which is protruded an aggregate of many small flowers, forming a sort of umbel. The flowers singly are composed each of six petals, which, though separately small, many being collected into large heads, are very conspicuous.

The *Allium Moly*, *Subhirsutum*, *Sphaerocephalon*, *Roseum*, and *Allium Flavum*, grow from twelve to fifteen or eighteen inches high, and their umbels continue a month in bloom.

The *Allium Magicum* and *Victorialis*, rise about a yard in height, and produce large and very ornamental umbels.

They flower in May, June, and July, ripen plenty of seed, and in some many small bulbs on the stalk and umbel.

Propagation, &c.

All the sorts may be propagated with the utmost facility by off-sets of the root, and many of them by seed, and the small bulbs on the stalk.

The Common Garlick is always propagated by the small bulbs that compose the main root, which may readily be divided into many separate cloves; these are to be planted in the spring, in beds four feet wide, in rows length ways six inches distance, four inches asunder in each row, and two or three inches deep, planting them either with a blunt dibber, or draw drills, and place the cloves therein, and cover them with the earth.

Being thus planted, they will shoot up their leaves in a month or six weeks; and all the culture they require is occasional small hoeing to kill weeds.

In the end of July or beginning of August, the bulbs will be full grown, as will be discoverable by the yellow hue and withering of the leaves; then take them up, clean and dry them in the sun, and tye or plait them in bunches to be hung up for use.

The Rocambole may be propagated either by the off-sets of its roots, or by the cloves produced on the stalks, which should be planted in autumn, by which, both the root and stalk bulbs will be considerably larger than if planted in spring.

These are to be planted as directed for the garlick, and they will be fit for use in July or August.

It is however to be observed, the roots never acquire a large size.

All the flowering kinds propagate very fast by off-sets, which may be separated any time after the decay of the flower, taking only the largest and plant them at once in the borders, and they will flower the following summer.

The propagation by seed is in a shady border in spring, and in autumn the plants will be fit to transplant.

ALLIUM-CEPA. The Onion.

We before noticed that the Onions are species of *Allium*, and under which genera we now range them; but to render the different species of that kind, and their culture more immediately conspicuous and intelligible for practice, we judge it eligible to adopt this mode of separate arrangement.

The characters, &c. are the same as the garlick already described.

The species are,

¹*ALLIUM-CEPA, Cepa.*

The Common Onion.] *Allium* with a great bulbous root, fistular taper leaves, the flower-stalk naked, and with the lower part bellied.

Varieties.] Strasburg or Common oval Onion.—Spanish silver-skinned large flat Onion.—Spanish red-skinned large flat Onion.—Portugal great oval Onion.

²*ALLIUM-CEPA Major Perenne.*

The Ciboule or Welsh Onion, or Major Perennial bulbless rooted Cepa.

³*ALLIUM-CEPA Schaenoprasum.*

Cives, or Minor Perennial bulbless rooted Onion.

⁴*ALLIUM-CEPA Ascalonica.*

The Escalot or Shallot, or Perennial bulbous Cepa, with oblong bulbs growing in a cluster.

The first species and varieties have large bulbous roots, the plants are biennial, i. e. being sown, one year come up and arrive at perfection in the root, next year shoot up into stalk, flower, and ripen seed, when the stalks quickly die, and the individuals are at an end.

The second and third species never form any bulbs at bottom, they are hardy and perennial, and may be continued many years by the roots. See their *Culture*.

The fourth sort is bulbous rooted, perennial, and multiply exceedingly by off-sets. Vide the *Culture*.

Propagation and Culture; and first of the Common Onion.

Of the four varieties of Common Onion, the Strasburgh is the best for general culture; it is a handsome bulb, generally assuming an oval

oval shape, is of firm growth, and keeps well for winter service.

The Spanish Onions are large and flat, the white sort is of mildest flavour. Both the varieties generally turn out very profitable crops, and none excels them for culinary purposes, but they rarely keep so well after Christmas as the Strasburgh or oval Onion.

The Portugal Onion is a very large handsome bulb, of somewhat oval shape, although they rarely attain the size here as in Portugal, &c. as is obvious by those imported annually from that kingdom by the orange merchants. If, however, seeds saved in Portugal are sown here, the bulbs will arrive at a much larger size than from seeds saved in England, especially if saved two or three years successively, which will often be so far degenerated, that the bulbs become flat, and not larger than the common onions.

This sort being very mild, is greatly esteemed for sauces, and other uses in cookery.

All these sorts are propagated by seed sown annually; which, for the general crops, the proper season is from about the twentieth of February until the latter end of March, observing however, in cold, wet, stubborn land, it is proper to defer sowing entirely until towards the middle of the last named month. It is likewise to be remarked, that in cases of omission in sowing at the times abovementioned, it may be performed in moist rich soils, with tolerable success, any time before the fifteenth of April; but remembering that the crops of the February or March sowing always bulb more freely, and acquire a much larger growth than those sown later.

The proper situation and soil for these crops should be an open exposure, and the land moderately light and rich; choosing however a spot of the best mellow ground in the garden, with the addition, if possible, of a good coat of rotten dung, which should be dug in, one spade deep, see *TRENCHING*, &c. observing to preserve a level surface; and while it is fresh stirred let the seed be sown, which is of particular importance. Do not however sow it when the surface is so wet or moist as to clog to the feet, or rake.

The proper quantity of seed is about an ounce to every rod or pole of ground, but if it is not required to have them thick for cullings, two ounces for three rods is sufficient.

Be particularly careful to procure fresh seed; for of that which is more than one year old, not one in fifty will grow.

The seed may either be sown all over the piece or plat of ground, and raked in; or the ground may first be divided into beds of four or five feet, allowing foot-wide alleys between; then sow the seed with a regular spreading cast, and immediately tread the surface over evenly; then pare the alleys an inch or two deep, and cast the earth over the beds, and directly proceed to rake them length ways, keeping an even hand, and trim off all stones, &c. See *SOWING SEED*.

The sowing them in beds is certainly the most eligible practice, when it is designed to draw or cull the young onions from time to time, for market or family service, because in such cases a person can stand in the alleys without treading at every turn upon the beds, which renders the surface hard, to the detriment of the crop, as well as unavoidably trampling upon the plants themselves; and it is likewise very convenient to stand in the alleys to weed, thin, or hoe the crop.

It is a common practice in the general culture of onions to sow them thick, to allow for culling or drawing out the superabundant plants by degrees as they are wanted. We, however, advise to sow a piece particularly for general culling, exclusive of the main crop, for by a daily thinning out the superfluous plants, there is no avoiding treading upon, disturbing, and loosening the remaining ones, and the plants thereby become of stunted growth.

Another very common practice is, the mixing of other crops, such as leek, lettuce, radish, carrot, &c. with the crops in question, a practice we declare against, as introducing confusion in general, and obstruction to the chief crop, without producing any considerable advantage; nothing therefore should be admitted, except, if thought convenient, a thin sprinkling of coss lettuce.

In fifteen or twenty days after the seed is sown, the plants will appear; and in a month or six weeks after that, they will be three or four inches high, and weeds will be numerous, when they should be cleaned from weeds, and thinned to three or four inches distance. The weeding and thinning should be began in due time, before the weeds branch and spread, which may either be performed by hand or small hoeing; the latter is the most expeditious method, as one man may do as much as three, and is also the most beneficial to the plants, for by stirring the ground about them with the hoe, it will greatly facilitate

litate their growth, as will be obvious in a few days after the operation; a small hoe two inches broad is the proper size; chuse dry weather, cut up all weeds, and where the plants stand close, cut them out to two or three inches distance; but if they are not wanted for culling, use a broader hoe, and cut them out to about four inches distance each way, having regard to leave the strongest and most promising plants.

In a month after run over them again with the hoe, and cut up weeds, and any superfluous plants that escaped you the first time; after this they will require no farther culture than pulling out straggling weeds.

In July the plants will begin to swell greatly at bottom, and in August the bulbs will be fully grown.

Towards the middle of August, therefore, examine the crop in general; when the necks shrink and fall, and the leaves wither, it may be presumed the bulbs are arrived at maturity, and are done growing, and should be pulled up, cleaned, dried, and housed for use: this should be done in dry weather; at the same time hoe and rake a piece of the ground clean, and as you pull the onions, spread them thereon to dry and harden. Here let them lie about a fortnight, turning them every day or two, when, if the weather proves dry, they will be duly prepared for keeping, then take the first opportunity to house them before wet weather prevails. Let the bulbs be first divested of all adhering earth, loose skins, and the grossest parts of the leaves and neck, rejecting all infectious and bruised ones; and carry them into any dry upper room out of the damp, spreading them on the floor not more than a foot thick, but if room to lay them thinner, it will be an advantage:

Being now housed, the closer the room is kept the better, observing to turn them over once in three weeks, and clear out such as have any tendency to infection, which they would soon communicate to others in their neighbourhood, and it would become general.

Observations.] In the culture of onions it often happens that, through badness of seed, many are disappointed of a crop, by waiting long in expectation of the plants rising, till it has been too late to sow again. In this case recourse may be had to transplantation from other gardens, either from a neighbouring one, where there are superfluous crops, or may purchase a bed, or such part of one as is ne-

cessary from a market gardener; this should be done in May, or early in June, and if possible in moist weather: having a spot of well-dunged ground prepared, take up the plants with good roots, and plant them in rows six inches distance, and four inches asunder in each row, giving directly a hearty watering.

Repeat the waterings occasionally for a week or fortnight, and the plants will grow freely, and you will not be disappointed; they will form handsome bulbs.

Onions for pickling are in great request. Those proper for that purpose should not be bigger than common round buttons; to procure which in due quantity, some seed should be sown late in a spot of light poor land; about the middle of April is the proper time: sow it moderately thick, and the plants need not be thinned except they rise in very thick clusters. They will bulb in June and July, and be fit to take up in August.

Right pickling onions sell well in the markets; those that are cleaned and trimmed ready for the pickling tub fetch from eight to twelve shillings per bushel.

In the spring many of the keeping onions will unavoidably grow as they lie in the house, these may be planted out in rows six inches distance, and will serve to draw up by way of escallions.

Of the Autumn or Michaelmas Crop.

This crop is generally sown in August, and the plants arise before Michaelmas, stand the winter, and are intended principally for spring service, to draw up young for sallads, &c. and likewise, if the Strasburgh or any other variety of the Common Onion are sown, they, if permitted to stand, will bulb to a tolerable size in June, and supply the kitchen or market as headed onions till those of the spring crop are bulbed.

But as the Common Onion is liable to be cut off in severe winters, it is necessary always at the same time to sow some beds of Welch Onions, which bid defiance to the most rigorous frost. See their *Culture*.

We observed above, that August is the season for sowing these crops; it is to be remarked, that in warm rich land, from the fifteenth to the twenty-fifth, is the proper period; but in cold or poor ground, always sow in the first or second week of that month, observing to sow them in beds four feet wide, with twelve inch alleys between; do not spare seed, and tread and rake it in as directed in the spring crop.

The plants will appear in a fortnight, and with them numerous weeds, to which early attention must be had to clear them out by hand before they begin to spread, but the plants of this crop are not now to be thinned.

In November and December however, if they stand very thick, some of the largest may be thinned out occasionally for use.

Of saving Seed of this Species.

February is the proper time to plant onions for seed, though this is often done in October by those that save great quantities for sale.

For this purpose make choice of a due quantity of the largest and handsomest bulbs, rejecting all blemished ones, and such as have already made any effort to grow, and having made choice of a spot of ground well exposed to the sun, which being dug, proceed to plant the onions; strain a line, and with a hoe or spade open three drills, twelve inches asunder, and six deep, place the bulbs therein nine inches distance, and rake the earth over them; measure off two feet for an alley, and plant three more rows as above, and in that manner proceed to the end; the wide spaces of two feet is by way of alleys to go between to hoe and clear off weeds, as well as to stake and support the stalks of the plants when necessary.

In June the flower stalks will be shot to their full height, and the flower heads will be formed at top, to secure which in erect position, drive some stout stakes in the ground along each row, at two yards distance, and from stake to stake fasten double lines of pack-thread, and if these are tied together in the intervals between the stems of each plant, it will effectually secure them.

About the latter end of August the seed will be ripe, which is very discoverable by the capsules opening, and the black colour of the seed; cut the heads in a dry day, and spread them upon cloths in the sun, but remove them under cover at night; and in a week or fortnight beat or rub out the seed; clean it from the rubbish, and put it up in bags for use.

Observation.] Good onion seed is a very material article to be attended to: it is to be remarked that this seed never germinates freely after the first year, but notwithstanding this, seeds-men are very apt to mix more than half old seed with their new, to the great loss and disappointment of many; to try its goodness, some, before they venture their general crop, sow a little in a pot, and place it in a moderate hot-bed, or near a fire; but the most expeditious

method is this, tye about a thimble-full of the seed loosely in a piece of linen rag, and put it into a vessel of boiling water, suspended by a thread; in ten or fifteen minutes pull it out, and if the seeds are good, they will in that short space of time be germinated or chipped, perhaps a quarter of an inch in length.

Leek and other seed of similar nature may be tried by the same experiment.

Culture of the second Species, Ciboule, or Welch Onion.

The *Ciboule* or *Welch Onion* is a perennial plant; this never forms any bulb at bottom, so merits culture only to draw as young green onions for fallads, &c. in spring, but on account of its strong temperament of taste, is greatly inferior to those of the Common Onion. However, as the plants being so extremely hardy as to survive the severest winter, that although their blades are generally cut off, the roots remain sound, and shoot forth with great vigour early in spring, and furnish a seasonable supply till May, when they generally run to seed, for which singular merit they demand general attention.

We noticed above of their being perennial; they are so in root, which encrease by off-sets into great clusters; but they are not to be propagated thereby for general use; their propagation is by seed, the same as the former sorts.

These are cultivated principally to stand the winter for spring service. The season for sowing them is in August. See *Michaelmas Onions*.

The plants will appear in twelve or fifteen days, and toward Michaelmas let them be carefully hand-weeded.

It is peculiar to this species to lose their tops in November or December, and remain divested thereof till towards Candlemas, when the roots shoot forth again; at this period it will be good culture to dig the alleys, and spread about an inch depth of the earth evenly over the surface of the beds; it will add vigour to the roots, the plants will rise strong, and all that part within the earth will be blanched white, which will be more agreeable to the eye, and the whole will be more tender and mild to eat, either alone or in fallads.

If the sowing of a Michaelmas crop has at any time been omitted, you may sow some seed of this sort toward the end of January; the plants will rise in February, and being hardy,

hardy, will continue growing, and be fit to draw in April.

To save plenty of seed of this species, it is proper to retain some plants for stools. In the end of March put out a parcel of strong young plants, nine inches distance, which will produce seed in August; let the roots remain, and in the following years will produce treble the quantity; but as they encrease into great bunches, the stools should be removed and separated every third year.

Culture of the third Species, the Cives.

This is the smallest of all the onion kind, it rising but a few inches high; but its roots are perennial, and encrease considerably into clusters, from which rise large tufts of slender awl-shaped leaves, which are the only part used, the roots never forming any bulb, at least not bigger than small peas.

This little hardy plant merits a place in every garden: its clusters of leaves rise early in spring, which being of an agreeably mild temperature, is very proper as a salad ingredient; and the method of gathering it is to cut the leaves off near the ground, and a fresh supply is soon produced from the bottom.

It is easily encreased by dividing the roots in spring, and plant eight or ten together in holes six inches distance, and by autumn they will be multiplied into large bunches.

Culture of the fourth Species, Escalot, or Shallot.

This species of onion is bulbous-rooted, which encrease greatly by off-sets, the largest of which are the proper parts of the plant for use.

The bulbs of this plant are oblong, irregular, and seldom grow large, because they generally encrease into clusters, that they cannot swell like roots that grow singly; from the root is produced many long, narrow, infirm leaves, coming up in spring, and wither in August, when the roots are full grown.

The propagation of this plant is by the smaller roots or off-sets; these may be planted in autumn, or early in spring; November is the proper time for the autumn, and February for the spring plantation; those of the former generally attain the largest size, particularly in light soils; they are to be planted in beds four feet wide, the off-sets to be planted singly in holes six inches distance, and two or three deep.

All the culture the plants require is to be small hoed occasionally, to destroy weeds.

Towards the end of July, or beginning of

August, the bulbs will have attained their full growth, as will be determined by the withering of the leaves; take them up in a dry day, and spread them in the sun to harden, then clean and bunch the largest for use, and reserve the smaller off-sets for propagation.

ALLIUM-PORRUM, the Leek, being the third and last division of the genus ALLIUM.

The general characters are the same as the Allium before described.

The species and varieties are,

ALLIUM PORRUM, *Porrum*.

The Leek.] Allium with an oblong tunicated root, plane cauline leaves, flowers gathered in close heads, and triple-pointed stamina.

Varieties.] Broad leaved or London Leek. — Narrow leaved Leek — Striped leaved Leek.

These plants may be deemed biennial; for although the roots often survive after perfecting seeds, yet the plants always attain perfection the same year they are sown, and next year they run up to stalk, and become unfit for use.

The seed-stalk of this does not belly like that of the onion.

The first of these three varieties is the sort proper for general culture, which attains a large growth, the neck acquiring a thick substance, in length from six to nine or ten inches, dividing upward into many large, long, thick leaves, arranging themselves fan fashion.

The second sort runs up with a long thin neck, and narrow thin straggling leaves, which, being a degenerate variety, do not merit culture.

The striped leaved kind is retained for variety, which may be continued by suckers arising from the old roots.

Propagation, Culture, &c.

The Common Leek is raised annually from seed sown in the spring; the proper time for sowing the general crop for autumn and winter service, is the same as advised for the onion, i. e. from the twentieth of February to the end of March; but for latter crops to stand for spring use, may sow any time in April.

It is a common practice with many, out of a false notion of making the most of their ground, to sow Leeks along with their crops of onions, which is what we would not recommend, having experienced it to be considerably

ably the best culture to keep them separate, though it is often practised by the market gardeners, when intending to cull out the onions from time to time for market, so that by a daily thinning they are often all cleared off by the end of July, and those being gone, the same ground remains occupied by a crop of Leeks; but this cannot be practised to advantage in the main crops of onions that are to stand to grow to full size for keeping.

The best culture therefore we would recommend for the general crops of Leeks, is to sow them pretty thick in a spot by themselves, to be afterwards transplanted.

The same situation, soil, and method of sowing, is to be observed as directed for the onion.

In June, July, and August, the plants will be of due size for transplanting: make choice of an open spot of the best ground, and if dunged it will be of much advantage, digging in the dung one spade deep; then draw a parcel of the largest Leeks, and trim their tops and the extreme parts of their fibres, and proceed to plant them by line and dibber in rows, which for the early crop should be twelve inches distance, and eight inches a-part in each row, and for latter crops nine inches between the rows, and fix the other way is sufficient, putting them three or four inches in the ground, or nearly to the length of their necks, and directly let them be watered.

All the culture they require is to be kept clean from weeds, which may be done with the utmost facility, by applying a sharp hoe in dry weather.

Leeks thus cultivated will be finer than those that remain where sown; their necks, which is the principal esculent part, will be much longer, and all that part within the earth will be finely whitened, and rendered mild and tender, which is a desirable property in the Leek.

The general season of Leeks for use, is from September until May, when they shoot up their stalks for flower and seed.

To save Leek seed, mark a quantity of the finest plants, and in February transplant them into a sheltered sunny border, under a wall, pale, hedge, or reed fence; this is necessary, because the seeds ripen late in autumn, and unless assisted by such situation and shelter, they do not ripen freely in England.

It would be of particular advantage to plant some in a row close along under the fence,

at ten or twelve inches distance in the row.

They will shoot up their stalks considerably in May, and in June will attain two or three feet stature, when they should be supported, and continued close to the fence. In July the flowers will be protruded from their sheath at the summit of each stalk, and form a large globular head or aggregate; and in September the seeds will begin to ripen. When that is effected, cut the heads with part of the stalk, tie them in bunches by threes, and hang them across lines in a dry airy apartment, two or three months, when the seed will be hardened, and the capsules will readily break by threshing or rubbing, to discharge it from the cells.

ALOE, the *Aloe Africana*, or African Aloes.

The number of Aloes is very considerable, many of them of singular beauty and curiosity; they are universally perennial, succulent, and evergreen, chiefly natives of Africa, and consequently require shelter here in winter, though the major part need only that of a green-house.

Former botanists, before Linnæus, having conjoined this genera and the Agave or American Aloe, on account of their conformity of habit, are now ranged as distinct genera, principally from this circumstance, that in the former the seed-bud or germen is placed within the corolla; in the latter, below it. There is also obvious differences in the growth of the plants; in the Agave the centre leaves are closely infolded, inclosing the flower-stem, and never flower but once, and that not till they have attained a great age, then perish, see AGAVE. In the Aloe the leaves are open quite to the centre, and the flower-stem is protruded from one side thereof, and the plants survive and continue flowering annually.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX none. COROLLA, one long tubular petal, six-parted, and spreading at the brim. STAMINA, six filaments, and simple antheræ. PISTILLUM, a germen placed within the corolla, a single style, and trifid stigma. PERICARPIUM, the germen succeeds to an oblong capsule of three cells, furnished with angular seeds.

The species are,

*ALOE *Mitriiformes*.

Mitre shaped Aloe.] Aloe with an erect stem, elevating, broad, erect, spinous edged, converging

verging leaves, and drooping flowers, in a nearly cylindrical corymbus.

²*ALOE Arborescens.*

Tree, or Sword Aloe.] Aloe with an erect shrubby stem, elevating, long, narrow, reflexed, indented, spinous leaves, embracing the stem with their base, and pyramidal spike of red flowers.

³*ALOE Ferox.*

Ferox, or Fierce-like Aloe.] Aloe with a shrubby stem, supporting broad, dark green leaves, embracing it with their base, and having every side armed with robust spines.

⁴*ALOE Plicatilis.*

Plaited, or Fan Aloe.] Aloe with a shrubby stem, supporting heads of long, compressed, sword-shaped, unarmed leaves, standing two ways, with the edges lapping over one another, and loose spikes of reddish flowers.

⁵*ALOE Vera.*

True Succotorine Aloe.] Aloe with an erect stem, long, narrow, spinous edged, succulent leaves, collected into diverging heads, and a long spike of red flowers.

⁶*ALOE Disticha.*

Horizontal, or Soap Aloe.] Aloe with a short stalk, broad, spotted, spinous edged leaves, spreading horizontally every way, embracing the stem with their base, and red flowers in umbels.

⁷*ALOE Variegata.*

Variegated, or Partridge-breast Aloe.] Dwarf Aloe with triangular, short, thick, variegated, white and green, slightly-fawed leaves, turning back at the ends, and ranged three ways; and flowers in loose clusters.

⁸*ALOE Linguiforme.*

Tongue-shaped Aloe.] Dwarf Aloe with short tongue-shaped, close growing, slightly spotted leaves, and drooping flowers.

Varieties.] Tongue Aloe with longer and deeply spotted leaves.—Tongue Aloe with broad, faintly spotted leaves, ranged closely together.

⁹*ALOE Verrucosa.*

Warted Tongue Aloe.] Dwarf Aloe with long tongue shaped leaves, concave above, and carinated below, ranged two ways, closely warted or studded with white tubercles, and drooping red flowers.

Varieties.] Warted keel-shaped Aloe, having broad, thick, keel-shaped leaves, and spread every way.—Warted coral Aloe, having broad, short, thick leaves, standing two ways, and coral coloured flower-stalks.

¹⁰*ALOE Margaritifera.*

Pearl Aloe.] Dwarf Aloe with clustered,

thick, short, triangular-pointed leaves, the points long and turn up, closely covered with pearly tubercles, and flowers having two lips, the upper one erect, the under one spreading.

Varieties.] Smaller Pearl Aloe, having very short leaves.—Least Pearl Aloe, having extremely short thick leaves.

¹¹*ALOE Arachnoides.*

Cobweb Aloe.] Dwarf Aloe with flat growing, short, plane, fleshy, triangular-pointed leaves, the edges closely set with numerous hair-like spines.

Variety.] Cobweb Aloe, with cylindrical, based, triangular-pointed leaves.

¹²*ALOE Retusa.*

Retuse-leaved or Cushion Aloe.] Dwarf Aloe with short, thick, swelling leaves, having triangular compressed ends; and trigonous flowers, having two lips, the under one rolled back.

¹³*ALOE Humilis.*

Humble, or Hedge-hog Aloe.] Aloe with short, erect, broad-based, taper leaves, triangular at the ends, and both surfaces closely set with spines.

¹⁴*ALOE Spiralis.*

Spiral upright Aloe.] Aloe with a short stem, closely set round with oval, sharp-pointed, imbricated leaves; and oval crenated flowers, without foot-stalks.

Varieties.] Pentangular Upright Spiral Aloe, having the leaves ranged five ways.—Triangular Upright Spiral Aloe, having triangular leaves, and these standing three ways, like a triangle.

¹⁵*ALOE Uvaria.*

Flag-leaved, or Iris Uvaria Aloe.] Aloe with very long, narrow, triangular leaves from the root; and a clustered spike of close-fitting, reflexed, imbricated, yellow flowers.

All these plants obtain different statures, from three inches to three yards, and are of various singular growths, producing leaves of many different sizes, shapes, and determinations. Some rise with erect stems, supporting leaves two or three feet in length at top; others are composed entirely of dwarf leaves, standing in a cluster on the crown of the root, of which, some grow flat to the earth, others grow erect, some spread every way, others range in two, three, and five different directions, and various other positions, that in the whole they afford a great source of variety.

The roots of all the sorts are fibrous and perennial.

The

The first six species rise with an erect stem, elevating the leaves; the others are chiefly of low dwarfish growth, with the leaves rising immediately from the root. The stalks and leaves are also perennial, at least the same leaves are of several years duration, and continue encreasing in size, attaining, in different species, from three inches to three feet in length, and from one to six inches broad at the base, and end in a point, and those of all the sorts are thick, succulent, and of fleshy substance. The flower-stems in all the sorts rise among the leaves, and attain from eighteen inches to three feet in height, the flowers standing in a spike at the top, each flower formed of one tubular petal, the colour chiefly red, and some are of a white and greenish hue, appearing at different times, but mostly in autumn.

All the sorts flower annually in their native soil, and most of them do the same here, especially if they are wintered in a stove.

The *Mitre Aloe* is so termed from the figure of its leaves; the stem is erect, and by degrees attain four or five feet stature, surrounded by broad, erect, dark green leaves, eighteen inches long; those at top form a head, and converge towards their extremity in form of a mitre.

The *Aloe Arborefcens*, *Aloe Ferox*, and *Aloe Plicatilis*, rise each with a strong naked stem, which, in many years growth, attains eight or ten feet in height, and supports the leaves at top, which attain two feet or more in length.

The *Succotorine Aloe* advances with an erect stem, gradually rising three or four feet high, supporting the leaves in heads at top, grow two feet long, and diverge every way.

The *Soap Aloe* rises with a short stem, eighteen inches or two feet high, adorned on every side with horizontal leaves, of a dark green colour, spotted with white, somewhat resembling the colour of soft soap, whence the plant derives the name.

The *Aloe Variegata*, *Aloe Linguiforme*, *Aloe Verrucosa*, and *Aloe Margaritifera*, are plants of humble growth, have no stalk, the leaves standing in a cluster on the crown of the root, and growing from six to twelve inches high.

The *Cobweb Aloe* rises but a few inches high, the leaves sit close to the earth.

The *Arachnoides* and *Aloe Humilis* rarely rise more than five or six inches high; the leaves stand in a cluster on the head of the root, and grow nearly erect.

The *Aloe Spinalis* rises ten or twelve inches

high, having a short erect stem, closely set with short thick leaves on every side, from bottom to top, placed one above another.

The *Aloe Uvaria* hath great singularity; the leaves rise in a great cluster from the crown of the root, very narrow, erect, and three or four feet long; the flower-stalk rises in the centre a yard or more in height, supporting a vast clustered spike of yellow flowers.

This is the hardiest of all the species, as it will sometimes succeed in a warm border.

Culture, Propagation, &c.

All these plants are natives of Africa, and other warm countries, and in this climate require the shelter of a green-house, from the end of September until the beginning of June, so must always be retained in pots. It is however to be remarked, that although these plants may be wintered very well in a green-house, yet if they are indulged with the temperature of the stove during that season, they more certainly produce flowers annually.

With respect to the general culture of all these plants, they may be placed in the full air from the beginning of June until the middle of September; but observing, if immoderate rains prevail, they should have occasional shelter, otherwise, they being very succulent, it would rot them. In summer, when the weather is hot and dry, they will need moderate watering twice a week, but in winter, in a green-house, once in two or three weeks is sufficient.

The plants in general should be shifted into fresh earth every year or two, and they will occasionally require larger pots, either of which operations may be performed any time in summer. See SHIFTING PLANTS.

When any of the leaves are decayed, broken, or bruised, they should be cut off close.

The propagation of the greater part of these plants is effected by the off-sets or suckers, which most of the sorts yield abundantly; and those that furnish none may be encreased by cutting off their leaves, which, with the aid of a hot-bed, emit roots freely.

The time of year for either of the above methods of propagation, is from the middle of June until the end of July.

The method is as follows.

In the first place prepare a compost of light sandy loam from a pasture, using the top spit, and almost an equal portion of sea sand; or in default of which, road soil; and if these are previously mixed and exposed in the full air and sun several months, it will be an advantage.

A L O

vantage : then, at the season above-mentioned, slip off the suckers from the parent plant, and observe if their bases are very moist ; lay them in a dry shady place three or four days, till they become dry and firm ; this done, get the pots, which should be forty-eights, or sixty-twos for the small sorts, and fill them with the compost ; plant one sucker in each pot, and directly give water, and place the pots in a green-house, or in a common frame, to be screened occasionally from the sun and violent rains, and in three or four weeks they will be firmly rooted ; and may then be fully exposed, but defending them however from excessive wet, which is apt to rot these succulent plants.

The propagation by leaves is necessary for such that afford no suckers. In June cut off some fresh under-leaves, and lay them on a shelf a few days, till their succulent bases are healed over, then plant them in small pots as above, and plunge them in a hot-bed, giving occasional shade, water, and fresh air.

The *Aloe Uvaria*, producing plenty of seeds, it may be propagated thereby at pleasure, which may be sown in autumn in pots, and sheltered occasionally in a frame till spring, when the plants will appear ; and in July plant them singly in pots, to be moved to shelter in winter ; for although the plants, when they have obtained a year's growth, will succeed in a warm border, it is nevertheless proper to retain some in pots, to be protected from frost.

The following are also of this genus.

¹*ALOE Barbadosis.*

Barbadoes, or Hepatic Aloe.] Aloe with broad, thick, erect, subulate, indented, sea-green leaves, and a loose spike of hanging yellow flowers.

²*ALOE Glauca.*

Glaucous, or Sea-green Aloe.] Aloe with a short stalk, the leaves embrace it, and stand two ways.

Variety.] Short, spreading leaved, glaucous Aloe.

The first sort requires the constant shelter of a stove in winter.

The substance known among druggists by the name of Aloes, is the inspissated juice of the *Aloe Vera* and *Barbadosis* ; the finest is that of the Succotorine Aloe, and is greatly used in medicine ; that of the other is commonly called *Hepatic Aloes*, and is used chiefly for horses.

The above juice is drawn from the plants

A L T

by expression or incision ; that of the Succotorine Aloe is yellow, bitter, and smells like myrrh.

ALTHÆA. Marsh-Mallow.

The plants are herbaceous perennials, of hardy growth, obtaining an annual stature of four or five feet, adorned on every side with large, roundish, velvety leaves, and mallow-like flowers.

Class and order, *Monadelphia Polyandria*, many stamina united in one body.

Characters] *CALIX*, two monophyllous cups, the outer one nine, and the inner five-parted at the brims. *COROLLA*, five heart-shaped petals expanding above. *STAMINA*, numerous filaments united in a pillar. *PISTILLUM*, an orbicular germen, many pointed style, and many stigma. *PERICARPIUM*, the calix becomes a round depressed capsule of many cells, containing kidney-shaped seeds.

The species are,

¹*ALTHÆA Officinalis.*

Common officinal Marsh-Mallow.] *Althæa* with angulated, pointed, and sharply indented downy leaves.

Varieties.] Common Marsh-Mallow with roundish angulated leaves.—Common Marsh-Mallow with deeply sinuated leaves.

ALTHÆA Cannabina.

Hemp-leaved Hungarian Marsh-Mallow.] *Althæa* with the lower leaves palmated, those above more deeply fingered.

The first species and varieties succeed in any common soil and exposure ; the second requires a dry soil.

The roots of all the sorts are fibrous and perennial, from which are produced strong, erect, tall growing stems, which, in the common sorts, are herbaceous and annual ; in the second somewhat woody, and of two or three years duration.

The stems of each sort rise four or five feet high, emitting side branches, adorned with simple leaves, in alternate arrangement, which, in the common sorts, are velvety ; in the other a little hairy, and from the angles of the branches and leaves proceed the flowers, which are reddish, composed each of five petals, shaped like those of the Common Mallow, but smaller, appearing in June and July, and seeds ripen in autumn.

All the varieties of the first grow wild in marshy places in many parts of Britain ; the second in Hungary.

The Common Marsh-Mallows are esteemed principally as medical plants, but are also admitted

mitted in gardens by way of variety; the second sort is also retained in the gardens of the curious.

Culture.

All the sorts may be propagated plentifully by seed sown in the spring, and the common sorts also by parting the roots at that season, or rather in autumn, when the stems decay, observing, if they are to be cultivated for medicinal uses, to plant them in beds fifteen or eighteen inches distance.

ALYSSUM, *Alysson*, or Madwort.

This genus retains many species, most of which may be deemed shrubby, herbaceous perennials, of the ornamental flowery kind, which attain from one to two feet stature, adorned with hoary leaves, and flowers in clusters at the ends of all the branches.

Class and order, *Tetradynamia Siliculosa*.

Characters.] CALIX is four-leaved, and deciduous. COROLLA, four petals disposed like a cross. STAMINA, two short and four long filaments, having broad antheræ. PISTILLUM, an oval germen, single style, and blunt stigma. PERICARPIUM, a round compressed pod, containing flat seeds.

There are many species, those of most note are,

¹ALYSSUM *Saxatile*.

Common yellow Rock Alysson.] Alyssum with a shrubby branching stalk, spear-shaped, entire, waved, soft leaves; and yellow flowers in panicles.

²ALYSSUM *Halimifolium*.

Sea Purslane-leaved Alysson.] Alyssum with shrubby trailing stalks, narrow, spear-shaped, pointed, entire leaves; and white flowers in clusters.

³ALYSSUM *Montanum*.

Mountain dark yellow Alysson.] Alyssum with shrubby trailing stalks, and diffused branches, spear-shaped, obtuse, hoary leaves; and dark yellow flowers in clusters.

⁴ALYSSUM *Deltoidium*.

Deltoid-leaved Alysson.] Alyssum with shrubby trailing stalks, lanceolate-deltoid leaves; and violet coloured flowers in loose spikes.

⁵ALYSSUM *Spinosum*.

Prickly Alysson.] Alyssum with erect branches, armed with spines; and white flowers disposed in clusters.

⁶ALYSSUM *Incanum*.

Hoary erect Alysson.] Alyssum with erect stalks, spear shaped, hoary, entire leaves; and white flowers in a corymbus.

⁷ALYSSUM *Creticum*.

Cretan yellow Alysson.] Alyssum with an erect herbaceous stalk; hoary, spear-shaped, entire leaves, and swollen seed pods; bright yellow flowers in clusters.

All these species are natives of France, Spain, Portugal, &c. but succeed here in any common soil of a garden, where moisture is not copious.

They have somewhat shrubby succulent stalks and branches, growing from one to two feet high, which, in the first six species, become woody and abiding; in the other, they being more herbaceous and succulent, seldom continue above two or three years: all the sorts are adorned with hoary leaves, and flowers produced in clusters at the end of all the shoots; each flower is composed of four cross-shaped petals, which, though small, being numerous on each plant, are very conspicuous, appearing at different times in summer, and succeeded by ripe seed in autumn.

The *Common yellow Alysson* produces erect stalks a foot high, dividing into many low spreading branches, each of which is terminated by loose spikes of flowers in May, and continue a month.

The *Alyssum Halimifolium*, *Montanum*, and *Deltoidium*, spread their branches each way upon the surface of the earth, having every shoot terminated by the flowers, which, in the former, continue five or six months.

The *Alyssum Spinosum*, *Incanum*, and *Creticum*, are of erect growth, the two former attaining two feet stature, the latter about eighteen inches, branching out upward, adorned with clusters of flowers, proceeding from the extremity of each branch, appearing in June, July, and August.

Culture, Propagation, &c.

As all these plants in their native climate prevail chiefly in rocky, dry, gravelly, and rubbishy places, the same should be imitated here in their culture; let them therefore occupy places in dry warm borders, &c. because in rich moist soils they become very succulent, and the frost affects them in winter.

All the species may be propagated by seed, and most of them also by slips and cuttings of their shoots.

The seed should be sown in April, in a bed of dry light earth, and the plants will be ready for transplantation early in autumn. The propagation by cuttings, &c. may be effected

fect in April, May, and June, in a shady border, assisted by occasional waterings.

AMARANTHUS, Flower-Gentle, Love-lies-bleeding, Prince's-Feather, &c.

The number of *Amaranthus* is very great; they are universally herbaceous and annual, some of which are curious ornamental plants, of singular beauty and elegance, attaining in stature from three to seven feet; some grow pyramidally, others branch out tree-fashion, &c.

Class and order, *Monoecia Pentandria*.

Characters.] **CALIX**, three or five coloured permanent leaves. **COROLLA** none, the leaves of the calix supply its place, and the flowers are monoecious. **STAMINA**, five filaments in each male flower. **PISTILLUM**, in each female flower an oval germen, three styles, and three simple stigma. **PERICARPIMUM**, an oval capsule of one cell and one seed.

The species that demand attention are,

¹**AMARANTHUS Tricolor.**

The Tricolor, or Three-coloured Amaranthus.] *Amaranthus* with an erect stem; oval, spear-shaped, three-coloured leaves; and roundish heads of flowers embracing the stem.

²**AMARANTHUS Melancholicus.**

Bicolor, or Two-coloured Amaranthus.] *Amaranthus* with an erect stalk; spear-shaped, pointed, two-coloured leaves; and flowers collected in a roundish head, sitting close to the stem.

³**AMARANTHUS Maximus.**

Tree Amaranthus.] *Amaranthus* with an erect tree-like stem, branching horizontally, and large, hanging almost cylindrical spikes.

⁴**AMARANTHUS Caudatus.**

Trailing spiked Amaranthus, or Loves-lies-bleeding.] *Amaranthus* with an erect stem, branching horizontally, and very long, hanging, and trailing cylindrical spikes.

⁵**AMARANTHUS Sanguineus.**

Bloody-leaved Amaranthus.] *Amaranthus* with erect stalks and branches, oblong oval leaves, compound erect spikes, and the lateral ones spreading.

⁶**AMARANTHUS Hypochondriacus.**

Dark purple Amaranthus, or Prince's Feather.] *Amaranthus* with erect stalks and branches; oval pointed leaves, and clustered erect spikes.

The first five species are tender exotic annuals, that require to be raised in a hot-bed, and the sixth is an annual of hardy growth. See their *Culture*.

These plants rise with erect stems, from two to seven feet high, rising annually in the

spring from seed; attain their full height, flowering state, and general perfection, in July; continue in beauty three months, perfect seeds in September and October, and in November the whole individual perishes.

The flowers of all the species are devoid of petals or flower-leaves; the leaves of the calix or cup, which are of a purple colour, and permanent, supply their place.

The *Amaranthus Tricolor* and *Bicolor* grow four, five, or six feet high, and assume a beautiful pyramidal growth, adorned with large and elegantly variegated leaves, which, in the former sort, are green, yellow, and bright red; in the latter, a dark purple, and deep crimson, very conspicuous, and appear with great lustre, and are the principal ornament of the plants.

The flowers of both these species sit close to the stalks in small round heads, and make no appearance.

The *Tree Amaranthus* is an annual of stately growth, and grand appearance; it rises with an erect substantial stem, seven feet high, at every ten or twelve inches sending forth many horizontal branches, ornamented with luxuriant, rough, green leaves; and large, long, roundish, purple flower-spikes, proceeding from the extremity of every shoot, and hanging loosely downward.

The *Amaranthus Caudatus* obtains three or four feet stature, branching out every way horizontally, adorned with large pale green leaves, and very long, pendulous, purple spikes, at the joints and ends of all the branches and shoots, some in clusters, others advance singly a yard in length, hanging down like a tail, and often trail on the ground, hence the plant obtained the old name, Love-lies-bleeding.

The *Bloody Amaranthus* rises a yard high, the stem and branches erect, terminated by large clusters of short cross-placed spikes, with an upright spike terminating each cluster; and the whole plant is of a blood-purple colour.

The *Amaranthus Hypochondriacus* grows three feet high, dividing into many erect branches, adorned below with dark liver-coloured leaves, and terminated by large clustered, erect, purple spikes; this, being an old resident in almost every garden, we admit it in the collection for variety: it is so hardy, that from the scattered or self-sown seeds many plants continue rising annually.

Use in Gardens, &c.

The first four species, when raised in their ultimate perfection, are great ornaments to the

the pleasure garden, and the *Tricolor* and *Bicolor* are the greatest beauties of the annual tribe. These two species are always cultivated in pots, and disposed with cock's-combs, &c. to adorn court-yards, and other conspicuous compartments contiguous to the main habitation, grand walks, lawns, and ornamental garden buildings. The other four sorts are choice furniture for large open borders, and other compartments that verge principal walks, and home lawns, &c.

Propagation.

The propagation of all the species is by seed annually in the spring, assisted by artificial heat.

The two first sorts particularly require the aid of different hot-beds, and constant shelter of frames and glasses, until the latter end of June, otherwise the plants cannot be obtained of due stature, which, if less than three or four feet, they make no figure.

The general season for sowing these two species is March, but to obtain them in early perfection, and forward enough to perfect seeds, it is adviseable to sow them in the first or second week in that month.

To raise these two curious annuals in their fullest lustre, it is necessary to be furnished with new hot dung, sufficient for two or three different hot-beds, together with as many different sized garden frames and glass lights. See ANNUAL PLANTS. The first of these hot-beds should be made for a one-light frame, and covered with light rich earth, four inches deep, in which sow the seed, see ANNUAL PLANTS, and raise the plants an inch or two high, admitting air in the day, and cover the glass at night with a garden-mat; then, when the plants have obtained the above size, prepare a second hot-bed, and prick the plants therein four inches distance; give moderate waterings, and occasional shade from the sun, till they have taken root, and admit fresh air daily by raising one end of the light, and continue the night-covering, and when the plants have grown here a month, they will meet and require more room, when a third and final hot-bed, of larger dimensions, should be made; place a frame thereon, and lay in four or five inches thickness of earth; then take up the plants with balls of earth about their roots, and plant each in a twenty-four sized pot; give water, and plunge the pots immediately in the earth of the bed, managing as above; observing, that according as the plants reach the glasses, the

frame must be as often raised or deepened, see ANNUAL PLANTS, continuing the lights always on, and tilt them at one end daily to admit air, giving water every day or two, and by the end of June the plants will have nearly attained their full stature, and the weather will be settled, when they should be brought forth and placed where they are to remain, observing to support each with a handsome strait stake.

The plants are to be continued in the pots, and their principal culture, after being placed abroad, is to supply them duly with water, which they will need every day in dry hot weather.

For more particulars on their culture, see ANNUAL PLANTS.

To obtain good seed of these two sorts, place some plants in a deep frame in September, to have occasional shelter of the glasses from wet and cold.

The propagation of the third, fourth, and fifth sorts, is also to be effected by the aid of artificial heat; the time to sow them is towards the latter end of March, or beginning of April. These three sorts however, being hardier, do not require the aid of but one or two moderate hot-beds; that is, to be sown and raised in one till they are two or three inches high, then transplanted into a new one, which will forward them greatly, and in which to remain until the beginning of June, then taken up with balls of earth to their roots, and planted where it is designed they shall remain to flower. Some may be planted in pots, but the principal part in the border, &c. giving water directly, and repeat it occasionally for a week, till they have taken root.

The sixth sort will rise freely in the common ground; but to obtain it in more early and greater perfection, manage it as the last three sorts.

The seed of the last four sorts ripen towards the latter end of September, when some of the largest spikes should be gathered and spread in the sun, in a dry airy room, for a fortnight.

AMARANTHUS, the Cock's-Comb. See CELOSIA.

AMARANTHUS, the Globe. See GOMPHRENA.

AMARYLLIS, Lily-Daffodil.

The plants are of the bulbous rooted tribe, and produce large liliaceous-like flowers, of extreme beauty and elegance.

Class

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, a spatha or sheath. COROLLA, six oblong spear-shaped petals. STAMINA, six filaments, with incumbent antheræ. PISTILLUM, a round germen, single style, having a trigonous stigma. PERICARPium, an oval capsule of three cells, enclosing round seeds.

The species of note are,

¹AMARYLLIS *Lutea*.

Yellow Autumnal Amaryllis.] Amaryllis with one equal flower from each sheath, having declinated stamina.

²AMARYLLIS *Atamusco*.

Atamusco Amaryllis.] Amaryllis with one equal flower, and declinated style.

³AMARYLLIS *Sarniensis*.

Guernsey Amaryllis, or Lily.] Amaryllis with many flowers in each scabbard, having revolute petals, and erect stamina and style.

⁴AMARYLLIS *Regina*.

Bella-donna Amaryllis, or Lily.] Amaryllis with many bell-shaped equal flowers in each sheath, and drooping stamina and style.

⁵AMARYLLIS *Bella-donna*.

Mexican Bella-donna Amaryllis.] Amaryllis with two or three bell-shaped equal flowers from each scabbard, and declinated stamina and style.

⁶AMARYLLIS *Zeylanica*.

Ceylon Amaryllis.] Amaryllis with a taper two-edged stem, many bell-shaped equal flowers in each scabbard.

⁷AMARYLLIS *Formosissima*.

Most handsome Amaryllis, or Jacobæan Lily.] Amaryllis with one large, irregular, nodding flower, and the stamina and style drooping.

⁸AMARYLLIS *Orientalis*.

Oriental Amaryllis, or Brunswigia.] Amaryllis with numerous irregular flowers in each sheath, and tongue-shaped leaves.

All these plants produce very pretty flowers; some are of singular beauty, and merit places in every curious garden, where there are conveniences for their culture. The two first are hardy, the third and fourth require shelter from frost; the other four need the aid of a stove.

General Description.

The roots are universally bulbous, mostly very large, and commonly oblong.

The flower-stem rises annually from the root, in most sorts naked and unattended by leaves, and attain different heights, from three inches to two feet, and at the termination or summit of each stem, is produced the

flower-bud, which is a sheath or scabbard, that bursts and protrudes the flower or flowers, which are large, and composed each of six oblong petals, of the liliaceous form, appearing chiefly in autumn, and when they fade the leaves come up, which are generally long and narrow, some large and flaggy, and which, together with the main bulbs and off-sets, continue growing until May or June, when the leaves decay, and is the time to remove or transplant the roots, and separate the off-sets for propagation.

The *Yellow Autumnal Amaryllis* attains but three or four inches in height, several stems rising in succession, each supporting one large yellow flower, in September and October.

The *Amaryllis Atamusco* sends up one stem, six inches high, elevating one large beautiful flower, carnation-coloured, changing almost white, appearing in summer or autumn.

The *Guernsey Amaryllis* is one of the finest flowers that can be seen. The stem rises a foot and half high, terminated by an oblong scabbard, from which bursts forth the cluster of flowers; the colour a bright shining red, spangled with golden specks, and a deep red vein running along the middle of all the petals. It flowers in October, and continues a month in full lustre.

The *Amaryllis Regina* sends up an erect firm stem, two feet in height, supporting an umbel of six or eight very large reddish purple flowers, in October.

The *Mexican Amaryllis* rises a foot high, crowned by two, three, or four large flame-coloured flowers, in March or April.

The *Ceylon Amaryllis* demands esteem both for its beauty and delightful fragrance. The stem attains two feet in height, surmounted by six or eight snowy white flowers, having all the petals beautifully streaked with lines of purple.

The *Jacobæan Amaryllis* is a flower of superior beauty, and singularity of form. The flower-stalk obtains fifteen inches stature, crowned by the flower, there being only one, which is very large; the colour a beautiful scarlet, with crimson filaments, and yellow antheræ; the petals are irregular, and their determination is curious, three of which droop, two stand horizontally, and one erect; the whole nods on one side of the stalk. The plant flowers in spring, autumn, or winter; and it is peculiar to the species, that after having sent up a flower-stem on one side of the bulb, it frequently sends up one or two more,

more, in successive order, from the other sides.

The *Oriental Amaryllis* sends up a robust stem a foot high, terminated by a large swelling scabbard, which protrudes a considerable spherical cluster of fine red flowers, each of which have five of its petals turned inward, and the sixth stands outward. It flowers late in autumn.

Culture, Propagation, &c.

The bulbs of all these plants may be purchased at most of the nurseries, and planted in August and September.

The two first sorts may be planted in any dry warm border, especially the first, where they will flower annually; the other being somewhat impatient of severe frost, it is also necessary to plant some in pots, to have occasional shelter in winter.

The *Guernsey Lily* requires protection from excessive wet and frost, so should be planted in pots to be moved to occasional shelter during their bloom, and from the rigour of winter.

Great numbers of these bulbs are imported hither annually from the Isle of Guernsey, for sale; they generally arrive in July, which if procured and planted before the middle of August, some of the large roots will probably flower the following October. The proper sized pots wherein to plant these bulbs are twenty-fours, which fill with rich, light, sandy earth, plant one root in each pot three inches deep, and place the pots where they may be screened from the mid-day sun during the hot weather, giving occasional moderate waterings, and about the middle of September, when the flower-bud will begin to make its appearance, remove them to the full sun, to remain till their flowers begin to expand, then place them to have occasional protection from rains and boisterous winds, either in a green-house, garden-frame, or any airy room.

When the flower fades, remove them into a garden-frame for the winter, to have occasional shelter of the glasses in times of violent rain, frost, snow, &c.

As it is peculiar to this species to flower somewhat reluctantly, inasmuch, that probably not five roots in twenty will perform that office the same season; therefore, permit the bulbs to remain unremoved three years, managing them as above, and they will afford a more considerable bloom the succeeding autumns. It is however always eligible

culture to transplant the bulbs once in the above period into fresh earth, and separate the off-sets, which plant either in pots, or in a bed of light dry soil, giving occasional shelter in winter, and in three years they will attain a flowering state, when they are to be treated as already directed.

The *Bella-Donna Amaryllis* is tolerably hardy, and will succeed in a warm dry border, with occasional shelter from frost. It is however advisable to plant some also in pots, and manage them as directed for the *Guernsey Lily*. If it is indulged with a stove, it generally flowers with greater lustre.

The *Mexican, Ceylon, Jacobæan, and Oriental Amaryllis*, are of tender temperature, which, though they may be preserved through the winter in a warm green-house, they rarely flower, unless the pots are plunged in a good hot-bed, under frames and glasses, towards the time of their respective seasons of flowering. All these sorts, however, succeed best in a stove, and where there are such conveniences, it is eligible culture to indulge the plants with that temperament of heat, when they will not fail to produce their beautiful flowers annually, and the *Jacobæan Amaryllis* often two or three times in that period of time.

All the sorts are propagated by the off-sets, or smaller bulbs, that arise annually from the sides of the main roots, which should be transplanted when their leaves decay, and the off-sets separated for propagation, and planted by themselves, and in two or three years they will attain a due size for flowering, when they are to be managed as above directed.

AMBROSIA.

The plants are chiefly herbaceous. There are six species, of which two only merit consideration.

Class and order, *Monoecia Pentandria*.

Characters.] CALIX, a monophyllous common cup. COROLLA, many male monopetalous florets in the same calix, and female apetalous flowers in different cups. STAMINA, five filaments in each male floret. PISTILLUM, in each female flower a germen, and style having two long stigma. PERICARPIUM, a leafy capsule of one cell, and one seed.

The species of most note are,

¹AMBROSIA *Elatior*.

Taller, Mugwort-leaved, Annual Ambrosia.] Ambrosia with doubly-pinnatifid leaves, and branches terminated by paniculated spikes.

²AMBROSIA

**AMBROSIA Arborefcens.*

Tree-like Peruvian Ambrosia.] Ambrosia with a shrubby perennial stem, pinnatifid, winged-like, hairy leaves, and the branches terminated by simple spikes.

The first sort is a hardy annual, that obtains three or four feet stature, and is of branching growth, producing clustered spikes at the end of every branch.

The *Tree Ambrosia* is a shrubby perennial, which grows eight or ten feet high, branching out upwards; the whole becomes woody, and of several years duration, and flowers annually; the flowers collected in simple spikes, proceeding from the end of all the branches.

The spikes in both sorts are amentaceous, and support both male and female flowers.

Both these species are exotics; the first is of Virginia, &c. and the second comes from Peru. The former succeeds in the common ground, and may be admitted in the collection of hardy annuals, in decorating the flower-borders; and the second is tender, so must be potted and placed among the green-house exotics.

Their propagation may be effected by seed in a moderate hot-bed or warm border, in March; and the *Tree Ambrosia* may also be raised with great facility by cuttings, which grow freely in a shady border in May or June.

AMENTACEOUS FLOWERS, from *Amentum*, having that species of calix or cup called *Amentum*. All Amentaceous Flowers are aggregate, and consist of a great number of minute flowers, and squamæ or chaffy scales, mixed alternately, and dispersed along a slender thread-like receptacle, which hang loosely down like a tail, and from the resemblance of some sorts to a cat's tail, has obtained the name of catkin. See **AMENTUM**.

The following genera are of the Amentaceous kind.

Birch, beech, hazel, horn-beam, walnut, oak, pine, poplar, juniper, cypress, arbutus, willow, &c.

AMENTUM, Catkin; defined to be a composition of scaly calix and flowers, disposed along a thread-like receptacle. The squamæ or scales that form the Amentum, mix alternately with the flowers, and resemble the chaff in an ear of corn.

AMOMUM, Ginger.

The plants are herbaceous exotics, of the East and West Indies, and are cultivated here in stoves for curiosity.

Class and order, *Monandria Monogynia*.

Characters.] **CALIX** is indented into three parts. **COROLLA** is monopetalous, tubular, and three-parted at the brim, and a nectarium in its bosom. **STAMINA**, one filament, and thick antheræ. **PISTILLUM**, a round germen under the receptacle, a single style, having a hairy stigma. **PERICARPIUM**, a trigonous capsule, having several seeds.

The species are four, those that merit notice are,

**AMOMUM Zinziber.*

Common Ginger.] Amomum with naked flower-stems, and an oval spike of flowers.

A²AMOMUM Zerumbet.

Zerumbet, or Broad-leaved wild Ginger.] Amomum with naked flower-stems, and oblong blunt spikes.

The plants grow three or four feet high, are perennial in root, but the stalks and leaves rise in spring, and perish in autumn.

The roots are thick, fleshy, jointed, and spread each way in the earth.

The stalks are reed-like, and grow erect; those of the first rise two feet and half high, the second above a yard; many such stalks often proceed from the same root, ornamented with leaves placed alternate, their bases embracing the stalks; those of the first are long and narrow, and in the second they are oblong and broader. From one side of the stalks arise the flower-stems immediately from the root, each terminated by the flowers, which are arranged in close, scaly spikes; those of the Ginger are blue, the other white.

Both sorts flower in autumn, and in November the whole decays to the ground.

The dried roots of the first species is that well known aromatic called Ginger, being much used for kitchen and medical purposes.

Their propagation is effected by parting the roots early in spring, before they shoot forth new stalks, planting the off-sets in pots of light rich earth, and plunging them in the bark-bed in the stove, giving occasional waterings, which, after they begin to shoot, they will need twice a week.

AMORPHA, Bastard Indigo.

There is but one species, which is a hardy, deciduous, flowering shrub, of tall growth, with long winged leaves, and butterfly-shaped flowers.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX** is monophyllous, tubulose, and five-parted at the margin. **COROLLA**

ROLLA is papilionaceous, but the wings and keel are wanting. STAMINA, ten filaments connected at their base, and simple antheræ. PISTILLUM, a roundish germen, single style, and stigma. PERICARPIUM, a moon-shaped leguminose pod, containing two kidney-shaped seeds.

The species is,

AMORPHA Fruticosa.

Shrub Amorpha.] *Amorpha* with false acacia leaves, and purple flowers.

This shrub rises ten or twelve feet high, advancing generally with several stems, which branch out irregularly, and produce large soft shoots, ornamented with long winged leaves, composed of many pair of lobes, and numerous small papilionaceous, dark purple flowers, in long spikes, proceeding from the extremity of the young shoots in summer, but it rarely ripens seed in this country.

It is a native of America, where, of its young shoots, was formerly prepared an inferior sort of Indigo.

For uses in gardening, this shrub may be employed to good advantage in composing large shrubberies.

The propagation of this plant is by seed, and layers of the young branches. The seed is procured from America, and sown in a bed of common earth in spring; the laying may be performed in that season, or in autumn, and by autumn following the layers will be fit to transplant.

AMYGDALUS, The Almond-Tree, which comprehends also the Peach and Nectarine.

According to the Linnæan system of botany, all the sorts of Peaches and Nectarines are retained as species of *Amygdalus*, under which genus we shall also range them; but to render the whole more intelligible for common practice in their cultivation, shall proceed in three divisions, the first division to contain those commonly considered as Almonds; second, the Peach-Tree, *Amygdalus-Persica*; and third, the Nectarine, *Amygdalus-Nucipersica*.

Class and order, *Icosandria Monogynia*.

Characters.] CALIX is monophyllous, tubular, and obtusely five-parted above. COROLLA, five oval concave petals inserted into the cup. STAMINA, twenty, or more filaments, and as many antheræ. PISTILLUM, a roundish germen, simple style, having a round stigma. PERICARPIUM, the germen becomes a large oval downy pulpy fruit, en-

closing a hard nut or stone, containing one seed or kernel.

First Division.

Of the Almond kind, the following are the principal species and varieties.

¹AMYGDALUS Communis.

Common Almond Tree.] Almond-Tree with foot-stalked, sawed leaves, and reddish flowers, in pairs, having the petals emarginated.

Varieties of this are,] Common Almond with bitter kernels.—Common Almond with a tender shell, and bitter kernels.—Common Almond with sweet kernels.

The following are also supposed to be only varieties of the Common Almond.

²AMYGDALUS Sativa.

Manured, or White flowered Almond-Tree.] Almond-Tree with linear-lanceolate, sharp-pointed, crenated leaves, and white flowers.

³AMYGDALUS Dulcis.

Sweet, Tender-shelled, Jordan Almond.] Almond-Tree with petiolate, short, broad, crenated leaves, and pale red flowers no longer than the calix.

⁴AMYGDALUS Orientalis.

Eastern Silvery-leaved Almond.] Almond-Tree with spear-shaped, silvery, short, foot-stalked leaves, continuing great part of the year.

⁵AMYGDALUS Nana.

Dwarf Almond.] Almond with low slender stems and branches, and petiolate leaves, narrowed at the base, and sawed on the margin.

Varieties of this are,] Dwarf Almond with single red flowers.—Dwarf Almond with double red flowers.

All these species and respective varieties are deciduous, and of hardy temperature, that prosper in any common soil of a garden. They are considered principally as plants of ornament, for the beauty of their early flowers, which surround all the young branches and shoots in great numbers, and are extremely conspicuous; they come out before the leaves, composed each of five small petals, and are universally hermaphrodite, appearing early in spring, and which, in the *Amygdalus Communis*, and *Sativus*, are frequently succeeded by plenty of ripe fruit in autumn, which, in all the varieties, obtains an oval form, and large size, is downy, and has a thick tough pulp, enclosing a large oblong nut or stone, containing a large kernel, which is the Almond, and the only esculent part of the fruit, many of which are extremely sweet and palatable.

The

The tree kinds flower early in March, and the fruit ripens in September; and the dwarf sorts flower the end of March, and beginning of April.

The *Amygdalus Communis* and varieties obtain about fifteen or twenty feet in height, and divides low into many spreading branches, which shoot strongly, but in time forms regular spreading heads, adorned in spring with innumerable flowers, arising closely all along the sides of the young branches and shoots, and in a manner covers them, continuing a fortnight or three weeks in full lustre, and make a fine appearance; and when they fade, the leaves, which are long and narrow, come out, and the fruit take their growth.

The several varieties of this species are frequently obtained from the seed or kernels of the same tree, of either sort; that with the sweet kernels is often cultivated as a fruit-tree, for the sake of the said kernels, and when once obtained, the sort is continued with certainty by inoculation. See their *Culture*.

The *Amygdalus Sativa* attains twelve or fifteen feet in height, is a moderate shooter, and the flowers small; but being white, numerous, and tolerably conspicuous, they form an agreeable contrast with the common sorts; but the blossoms being impatient of cutting frosts, they are rarely succeeded by much fruit, unless the trees have a sheltered situation, or are trained against a south wall.

The *Amygdalus Dulcis*, and *Orientalis*, rise twelve or fifteen feet high, they shoot moderately, and produce very small flowers, but rarely any fruit in England.

The two varieties of Dwarf Almond are low shrubs, that seldom exceed three or four feet in height; the stems are slender, and send forth numerous feeble branches near the ground, and the single flowered sort send up many suckers from the root. Both these shrubs have all their young branches closely adorned in spring with flowers, which, being of a fine pale red colour, very numerous, and showy, make a beautiful appearance for about a fortnight, and are some of the greatest ornaments of the spring.

The single sort flowers the end of March, and the double kind early in April, each continuing about a fortnight.

Use in Gardens, &c.

For uses in gardening, these trees are esteemed chiefly for the beauty of their flowers; but some of the tree kinds also demand attention as fruit-trees, and being of moderate

growth, they may with propriety be admitted in gardens of any extent.

Those that have the greatest claim to esteem, are the Common Almond, White flowering Almond, and the two varieties of the *Amygdalus Nana*. Of the two former, a few standard trees disposed alternately in shrubberies, or any ornamental plantation, have a fine effect in the spring season, and are particularly ornamental on the boundaries of grass lawns, contiguous to the mansion-house. Some trees dropped singly in different parts of large pleasure grounds, will appear to great advantage during their bloom; and after the flower is past, the progress of the growth of the fruit of the two former sorts affords amusement to the curious.

Sometimes curious persons train a few of the Common and White Almond, as dwarfs, or half standards, against walls, or in espaliers, to obtain larger, forwarder, and better flavoured fruit, managing them as peach-trees.

The two sorts of Dwarf Almonds, being shrubs of great beauty during their bloom, are proper furniture for the most conspicuous compartments of shrubberies, and should occupy places near the front, with shrubs of lowest growth.

The other two species are also cultivated in some curious gardens for variety, especially the Jordan Almond.

Propagation, &c.

The Common Almond and varieties may be propagated either by sowing the stones of the fruit, or by budding them upon plumb, or almond stocks.

With respect to these two methods of propagation, those that are budded sooner form full and regular heads, and they likewise sooner attain a state of flowering and producing fruit; and besides, if it is intended to continue the Sweet Kernelled, or any other particular sort, it can only be done with certainty by inoculation; as when raised from seed they vary, and all the varieties often rise from the fruit of the same tree. The inoculation is performed in July, in the usual method, and may be budded either for dwarfs, half or full standards; see INOCULATION. The first shoot from the bud is to be shortened in spring to four or five eyes, that it may put out lateral shoots to form a regular head, and in two or three years after they may be transplanted, either for bearing fruit, or for the purposes of ornament.

The

The second, third, and fourth sorts are also commonly propagated by inoculation, managing them as above.

To raise these trees from the stones, they should be planted in autumn, i. e. October or November; chuse those of the same year's growth, and drill them in three inches deep, in a bed of light earth, the plants will appear in spring, and in autumn or spring following, transplant them in rows in the nursery, where you may train them either for standards, half standards, or dwarfs, according to your fancy. See STANDARDS and DWARF-TREES.

If it is intended to bud any of them, either with Almonds or Peaches, they will be fit for that operation for dwarfs, some the first, and all of them the second summer after transplanting; but for standards they should have three years growth, to be trained with proper stems. See INOCULATION and GRAFTING.

The two dwarf sorts are also sometimes propagated by budding upon plumb or Almond stocks; they may also be raised with great facility by suckers from the roots, which the single kind particularly yield in great plenty; or, in default of which, both sorts may also be raised expeditiously by layers.

Second Division.

AMYGDALUS-PERSICA, the Peach-Tree, being the second division of the genus *Amygdalus*. See AMYGDALUS.

Class, order, and characters, the same as the *Amygdalus*.

The varieties of Peaches are very great, and by continuing to raise them from the seed or kernel, they may be multiplied indefinitely. It is to be observed, however, that notwithstanding the number of varieties that may be obtained that way, it is probable not one in twenty is possessed of the proper qualities, as is obvious by the cultivated sorts now known in England; for most of the eminent nursery-men retain no more than from twenty to thirty sorts in their catalogues, which they sell as real good peaches. Some indeed extend them to forty or fifty, but among which there are many of very indifferent qualities, and not worth the space they occupy; and since it is not more expence to cultivate the best than the more indifferent ones, the first only deserve our regard; and as all the sorts require to be trained against walls, the expence of building them is very considerable, and a good aspected wall is too valuable to be filled with any but the capital sorts. See WALLS, &c.

These fruit are divided into two classes, i. e. Peaches and Pavies; the former are distinguishable by the flesh or pulp readily quitting the stone, that of the latter firmly adheres thereto.

Botanists allow only one distinct species of Peach-Trees, all the different sorts of fruit are varieties of one another, so that the trees of all the varieties bear the particular marks of the original species; which is,

AMYGDALUS-PERSICA, *Persica*.

The Peach-Tree.] *Amygdalus* with sawed leaves, and solitary flowers, sitting close to the sides of the branches.

Varieties of the fruit are,

¹*Early White Nutmeg Peach.*] A very small oblong whitish fruit; ripe middle of July.

²*Early Red Nutmeg Peach.*] A small, roundish, bright red fruit; ripe end of July.

³*Anne Peach.*] A small, round, yellowish white fruit, faintly tinged with red on the sunny side; ripe early in August.

⁴*Small Mignon Peach.*] A smallish round fruit, red on the sunny side; ripe towards the middle of August.

⁵*Great Mignon Peach.*] A large round fruit, swelling on one side, and beautifully spotted with red next the sun; ripe about the middle of August.

⁶*Early Purple Peach.*] A large, round, purplish red fruit; ripe middle of August.

⁷*Late Purple Peach.*] A fine large, round, dark red, or purple fruit; ripe middle of September.

⁸*White Magdalen Peach.*] A middle sized, round, whitish fruit, one side deeply furrowed; ripe early in August.

⁹*Red Magdalen Peach.*] A beautiful large, round, red fruit; ripe end of August.

¹⁰*Early Newington Peach.*] A middle-sized roundish fruit, elegantly red on the sunny side; ripe in August.

¹¹*Old late Newington Peach.*] A fine large round fruit, beautifully red next the sun; ripe middle of September.

¹²*Montauban Peach.*] A middle sized roundish fruit, cleft on one side, and almost wholly of a purple-red colour; ripe towards the end of August.

¹³*Belle Chevreuse Peach.*] A middle-sized beautiful red fruit, of an oblong figure; ripe end of August.

¹⁴*Noble Peach.*] A very large roundish fruit, finely marbled with a purplish red; ripe beginning of September.

¹⁵*Yellow Alberge Peach.*] A middle-sized, some-

somewhat longish, yellow-fleshed fruit; ripe about the middle of August.

¹⁶*Belle Garde Peach.*] A fine, large, roundish fruit, almost wholly of a deep purple colour; ripe beginning of September.

¹⁷*Chancellor Peach.*] A large, somewhat oblong, bright red fruit; ripe end of August and September.

¹⁸*La Teton de Venus, or Breast of Venus Peach.*] A pretty large, somewhat longish fruit, deeply divided on one side, both divisions swelling and rounded like a woman's breast, and of a pale red colour on the sunny side; ripe towards the end of September.

¹⁹*Rossana Peach.*] A middle-sized, somewhat oval fruit, purple next the sun; ripe early in September.

²⁰*Perfique Peach.*] A fine large, roundish, and somewhat oblong fruit, terminated at top by a small nipple, having the sunny side red, the other pale green; ripe early in October.

²¹*Admirable Peach.*] A very large, round fruit, beautifully adorned with red next the sun; ripe beginning or middle of September.

²²*Rambouillet Peach.*] A large, longish, deeply-furrowed fruit, the sunny side beautifully reddened, the other yellow; ripe towards the end of September.

²³*La Royale, or Royal Peach.*] A large, round, almost wholly red fruit, but deeply reddened next the sun; ripe end of September.

²⁴*Bourdine Peach.*] A large, round, very fine fruit, bright red on the sunny side; ripe beginning or middle of September.

²⁵*Bloody Peach.*] A middle-sized, deep red fruit next the sun, and its whole pulp of a blood red colour; ripens late in October.

²⁶*Nivette Peach.*] A very fine, large, longish, deep purple fruit next the sun; ripe middle of September.

²⁷*Portugal Peach.*] A large, round, even Peach, generally spotted, and the sunny side elegantly reddened; ripe towards the end of September.

²⁸*Royal George Peach.*] A middle-sized, round Peach, furrowed on one side, of a deep red next the sun, the other part white, spotted with red; ripe early in September.

²⁹*Violet Peach.*] A middle-sized, roundish, oval, violet-coloured Peach; ripe towards the middle of September.

³⁰*Catharine Peach.*] A beautiful, very large, round Peach, the sunny side wholly of a fine bright red, the other side white; ripens in October.

³¹*Monstrous Pavie of Pomponne.*] An amazingly large and beautiful Peach, the shape round, and often measures twelve or fourteen inches in circumference; the side next the sun is deeply reddened, and the other assumes a pale flesh colour; ripe about the end of October.

³²*Cambray Peach.*] A middle-sized, longish, pale-coloured Peach; ripe in October.

³³*Sion Peach.*] A large, handsome, round Peach, reddish on the sunny side, the other side whitish; ripe end of September.

³⁴*Narbonne Peach.*] A very large Peach, almost wholly of a greenish colour; ripe in October.

The above thirty-four varieties of Peaches are the principal sorts of that universally admired fruit, known in Great Britain; and the name here annexed to each variety, is that by which they are generally known to all the nurserymen, who cultivate the trees for sale, to supply noblemen and gentlemen's gardens.

Many of the above varieties approach so near to one another in size, shape, and colour, that it is sometimes difficult to determine their difference without the strictest attention.

We do not pretend to recommend all these varieties as real good Peaches, but for the sake of those who have large extent of walling, have collected all the principal sorts to view, with short descriptions of their sizes, shapes, colours, and times of ripening, which it is presumed will convey some idea of the respective varieties to the unexperienced, and help to direct him in the choice of the sorts.

The sorts that have the greatest claim to esteem, as the best and most beautiful, both in regard to size, shape, colour, flavour, and the best bearers, are the following.

The Anne Peach, Small Mignon, Great Mignon, Red Magdalen, Belle Garde, Belle Chevreuse, Montauban, Admirable, Early Newington, Late Newington, Bourdine, Nivette, La Royale, Purple, Teton de Venus, Catharine, and Great Pavie of Pomponne; the latter chiefly for its prodigious size and beauty, and, as a pickle, it surpasses all the other sorts.

The two Nutmeg Peaches, though of small size and indifferent flavour, especially the white sort, they, on account of their early perfection, should also be allowed a place in the collection.

The Bloody Peach merits a place more for singularity, than for the quality of the fruit.

The two Newington Peaches, Portugal, Catharine, and Monstrous Pavie, may be deemed of the Pavie tribe, their flesh adhering closely to the stone. The Old Newington and Catharine are esteemed two of the most valuable Peaches that are cultivated in England.

Peach trees in general will grow fifteen or twenty feet high, if they have full scope; and if trained for standards, and permitted to take their natural growth, they form regular heads, but they do not ripen their fruit well on standards in this country, they being natives of a much warmer climate; so that, to effect the ripening of their fruit perfectly, they require the shelter of a warm wall, to which their branches should be regularly trained.

The trees in general flower early in spring; the flowers come out before the leaves, appearing chiefly on the shoots of last year, arising some singly, others in pairs, all along the sides of the shoot, to which they sit close; they are formed each of five small petals, and many stamina in the middle, with a small round germen, which becomes the Peach.

Of their Propagation.

The general propagation of Peach-trees is effected by budding them upon plum stocks.

But all the fine varieties of these fruit were originally obtained from the seed or kernel, and more new varieties may be gained by that means; but as we formerly observed the process is somewhat tedious, and often terminates in but trifling success, in respect to the quality of the fruit so obtained; for if you plant the stones of the finest sorts, it is a thousand to one, if, out of a great number, you obtain one like the originals, and but few that have any real merit, so greatly do these, and indeed all other fruits, vary from the seed. However, for the sake of experiment, there are many who have curiosity and patience enough to undertake the acquisition of new varieties by the above methods, and think themselves amply rewarded if they gain one or two new sorts that possess good qualities in respect to size, form, colour, and flavour.

The method of planting the stones for that purpose, is, they should be planted in autumn, in drills two or three inches deep, and in spring following they will come up, and after having one summer's growth, they should, in autumn or spring following, be transplanted in rows in the nursery, and in a year or two after may be planted against any spare wall, pales, or reed fence, and trained

as other Peach-trees; and when they have shown fruit, those of merit should be planted where they are to remain, which you may propagate or encrease by budding, as hereafter directed.

The only method of propagation, however, to continue, with certainty, the approved or any acquired sorts of Peaches, is by budding, i. e. inoculation; since, by inoculating the bud of a tree of any of the kinds, in the stem or stock of any sort of Peach, Almond, or Plum, the bud unites with the said stock, the head of which being cut off, the bud shoots forth, branches out, and becomes a Peach tree, which will produce fruit in size, shape, colour, and flavour, exactly the same as that of the parent tree from whence the bud was taken, and by which means you may multiply any of the sorts of Peaches, and other fruit trees at pleasure, and with certainty, see INOCULATION; and besides, trees thus raised, much sooner attain a bearing state than those from the kernels.

Peaches, as above hinted, may be budded upon three or four different stocks, viz. upon those raised from their own kernels, upon the almond, apricot, and plum. See STOCKS.

There is however but one sort of stock proper for general use whereon to bud Peaches, which is that of the plum; the Peach, the almond, and apricot stocks, are often attacked by the gum, and communicate it to the trees just as they arrive at a state of full bearing, and quickly go off; whereas, the plum stock being in every respect hardier, and better suited to different soils, Peaches budded upon them are generally healthful, and of long duration; observing, however, that experience has proved them to be the most prosperous and durable on one particular sort, which is that of the true muscle plum.

The propagation or raising stocks from the varieties of plums indifferently, as also of Peaches, almonds, and apricots, may with great ease be effected by sowing the stones of the fruit in autumn, in drills two inches deep, and they will rise freely the spring following; and in October they may be transplanted in rows two feet and half distance, and in the two following summers, those that are intended to form dwarfs, may be inoculated with Peach-buds.

But in respect to the real muscle plum stock, this cannot be obtained in its true state from the stones, for they vary so greatly when raised from seed, that not one in a hundred

hundred will prove of that sort; therefore, the only method to obtain the true muscle kind is either by layers in autumn, or by suckers that are sent up from the roots of Peach or plum-trees, that are known to be worked upon that sort of plum. These should be collected in October or November; chuse those that are about the size of a large goose-quill; cut off any knots of old wood that adhere to their roots, and trim off all side-branches, and plant them in lines two feet and half distance, and in the following summer some will be fit to bud for dwarfs.

The proper sized stocks to bud upon to form dwarfs, should be about half an inch thick.

But if intended to form half or full standards, the stocks, before they are budded, must be permitted to form stems an inch thick at bottom, and four, five, or six feet in height. See STOCKS, NURSERY, INOCULATION, &c.

The season for budding them is August, though some perform that work in June and July; but when budded too early, the buds are apt to shoot the same year, which shoots, being weakly, are either killed in winter, or, if they escape the frost, they never make great progress; therefore, from about the 25th of July to the 25th of August is the proper period for that operation, and the buds will remain dormant till spring, when they will shoot forth with vigour.

The method of performing the operation of budding, and every thing relating thereto for those and other trees, is fully explained under that article. See INOCULATION.

We shall therefore only observe, that as Peach-trees require to be trained against walls, &c. they should be budded principally to form dwarfs, that their branches may at first come out low, so as they may by degrees be trained to occupy every part of the wall, from bottom to top; the stocks should therefore be budded within five or six inches of the bottom, but where there are high walls to furnish, it is necessary also to raise half-standards and standards, to occupy the upper part, while the dwarfs are gradually advancing to cover the whole; the stocks, to constitute such standards, should for half standards be budded at the height of three or four feet, and for full standards at that of five or six, or they may be budded near the ground, and the first shoot from the bud trained to the above heights to form a stem.

Observe to insert only one bud in each stock, the heads of which are to remain on entire until spring.

In March following, the heads of all the stocks are to be cut off sloping, just above the place of insertion of the bud.

Soon after this the buds will shoot forth, each will produce one strong erect shoot, which, by autumn, will probably attain three or four feet in height, and the trees have then acquired their first state of formation, which, in October or November, should be transplanted in the places where they are finally to remain; and in the spring after that they must be headed down to a few eyes, to procure laterals near the place of inoculation, to give the tree its suitable form for the wall, and in two or three years they will bear fruit. See *Planting the Trees, Heading Down, &c.*

Of the Situation, Aspect, and proper Soil for these Trees.

With respect to situation and exposure, the Peach-tree being originally a native of warm climates, is, in some respects, tender, and will not prosper, at least not bear well, in an open situation; so that for the general part, require to be trained against walls.

The trees themselves, though hardy enough in respect to cold, yet the blossom and young fruit are extremely impatient of frost and cutting winds, which generally reign in this country at early spring, when the trees bloom and set their fruit: the trees, therefore, should be indulged with the shelter of a warm wall, or other substantial close fence, to which they should be planted close, and their branches regularly trained, which is necessary, not only to defend the blossom and young fruit the better from the inclemency of the weather, but also that they may have all the advantages of the sun's influence, to accelerate its ripening, as well as to give it colour and flavour, which many sorts, even with all the aid in our power to give, hardly effect in unfavourable seasons in this country.

The proper aspected walls or exposure for the fine sorts, is that of a due south; some may also be planted upon an east aspected wall, and in favourable seasons the trees will also sometimes set and ripen fruit tolerably on a western aspect. However, where there is walling enough, let the capital sorts be always planted against such walls, &c. that enjoy the greatest degree of the south sun, as even that aspect, in some seasons, is barely sufficient

sufficient to ripen some of the late sorts of these fruit, in any part of this island.

Such of the forward kinds that you desire as early as possible, should have the warmest situation on the best south wall, which, though some are inferior in size and flavour, yet when obtained at the earliest season, they are highly acceptable as a rarity in the desert.

With respect to soil, the Peach-tree will prosper in any common soil of a garden, where it is not less than fifteen or eighteen inches depth of proper staple, i. e. such that is proper for the culture of common kitchen herbage, and where moisture is not very copious; but if the depth of good soil in the fruit-tree borders is two or three feet, it will be the greater advantage.

The breadth of the borders against the walls, where it is intended to plant these trees, should never be less than three, but those of six or eight feet is the most proper width.

If the natural soil of the borders is of a moderately light, pliable nature, and of proper depth, it is a happy circumstance; and if it is of a loamy temperature, it will also be a particular advantage, provided however there is such depth of proper staple as above noticed, before you come at gravel, clay, or any other bad soil at bottom, when nothing more than common digging is necessary; but where there is less than that depth, the borders must be raised with a due portion of good fresh earth and rotten dung, working the whole well together.

Where good rich or pliable loam could be easily obtained from the surface of some contiguous pasture, common, or other field, and with store of rotten dung, working or blending the whole with the natural soil of the border to the proper depth, it would form a fine compost, and the trees will prosper, and be of long continuance.

But if the soil is naturally stiff and clayey, or of any other stubborn or very moist nature, it may be mellowed by adding dry substances, such as coal ashes, drift sand, road soil, and other similar materials, and plenty of rotten dung, working the whole with the natural soil to the above depth.

Where any one is so happy to possess a soil whose natural goodness renders all foreign assistance unnecessary, no more need be done than digging the borders one or two spades deep, and it is fit for the reception of the trees. See KITCHEN-GARDEN, BORDERS, &c.

Of Planting the Trees.

The season for planting is October and November, or even any time in open weather till March, in dry warm soils; but in moist or wet soils, we prefer the spring for that work.

Peach-trees, and, in short, all others that are designed for walls, should be planted in their places of final destination when they are one year old, i. e. when their heads are of one summer's growth from the bud, and with their said heads entire for the present, (see *Heading them down*) that we may have the opportunity of training them from their origin, as it were, and in their proper position in the places where they are finally to remain; for the great art in forming a wall-tree depends entirely upon the due pruning and training the two first years, after making the first shoot or head from the budding.

But if any one is in haste to have his walls covered at once, as it were, with bearing trees, he may be supplied with such at most of the nurseries, which are what the nursery-men call trained trees, which they sell from five to ten shillings per tree, according to the sorts, size, and property of growth. Every one may do as they please, but for my own part I always preferred those of one year from the bud; for these reasons, first, that trees of that age sooner and more firmly establish their roots, which is an essential point to keep in view; and secondly, because I would have the tree under my own management from the beginning, which I always found to be of importance.

The distance these trees should be planted from one another is fifteen feet, and if the walls are high, half or full standards may be planted between the dwarfs, to occupy the upper part while the dwarfs grow up to fill that space, for no part of good walls should be left unoccupied.

The rule is this, if the walls are not above six or eight feet high, plant none but dwarfs, and these at fifteen feet distance; if the walls are nine feet high, half standards, of about three or four feet stem may be planted between the dwarfs; and if the walls are ten or twelve feet, or more in height, full standards, of six feet stem, should be planted to occupy the upper part; and as the dwarfs are to be the principal residents, way must be made, as their branches gradually advance, by cutting away the lowermost ones of the standards by degrees annually, and at last, in seven, eight, ten, or more years, as you shall see necessary, the

the standards may be entirely taken away, that the dwarfs may advance, and fill the whole space of walling.

The mode of planting being fixed on, mark out on the walls the distances as above for the trees.

Then, having recourse to the nursery, let the trees be taken up with all their roots as entire as possible, for this is of much importance; the extreme ends of all of which should be tipped, i. e. a little shortened, and those of broken or bruised ones smoothed, see *PLANTING*, preserving the heads entire for the present. Holes or pits are then to be opened, capacious enough to receive the roots freely every way. Place the tree therein, about three inches from the wall, with the bud outward, and then break and trim in the earth regularly between all the roots and small fibres, and tread the whole gently, to fix the whole plant in its proper position; then directly tack the head to the wall, or tye it to a stake, to secure it from the power of boisterous winds till March, when it is to be headed down. See *Heading Down*.

If the ensuing spring or beginning of summer should prove very dry, indulge the trees with moderate waterings once or twice a week, according to the drought and heat of the season, which will encourage them to push out more freely and strong after heading down.

Of Heading Down, and Manner of Pruning, to give the Trees their due Form.

The trees being planted with their first heads from the bud entire, as we advised; the next necessary culture is to perform the operation of heading them down, which is to be done just as they begin to shoot, and the proper time is March.

This work consists in shortening the head, or first main shoot down within five or six eyes of the bud, or place of its origin, stopping it off on the side next the wall, just above an eye, which is a necessary operation, both to dwarfs, half, and full standards, that are planted against walls; that by stopping its upright direction, it may throw out several lateral shoots from the remaining lower part to the right and left, and constitute the proper foundation for forming a wall-tree, whose first branches should always proceed on both sides, from within six inches of the place of inoculation, whether dwarfs for the lower part, or standards for the middle and top of the wall; and that if the heading down was

omitted, the consequence would be, the tree would advance with a naked stem, and leave almost one half of the allotted space of walling unoccupied.

Therefore, pay no regard to the first head from the bud, howsoever large and fine it may appear, but cut it down as above; for the general formation of the tree depends entirely upon the form acquired by this practice, and the two succeeding years pruning. See *Heading down Trees*.

First Pruning after Heading Down.] The trees being thus headed down, they will soon after produce one strong shoot from each remaining eye, observing that such as proceed immediately from the front and back, are to be constantly rubbed off close, but all those that advance from the two sides are to be preserved entire, which, in June, when of due length to admit of laying in, should be nailed close to the wall, continuing them thereto at full length during the summer.

At the fall of the leaf following, proceed to give them their first winter pruning.

This may be done any time from November till March: you are now to examine the number of shoots each tree produced the preceding summer from the effect of heading down, and to prune them accordingly; for example, if there are two shoots, one on each side, they are both to be retained, and to encourage their furnishing a farther supply of branches, shorten them to eight or ten, or if of very strong growth, to twelve or fifteen inches, and nail them horizontally to the wall.

If there are three shoots, the middle one of which is to be cut out close, and shorten the other two as above, and nail one to each side in a horizontal direction; but if the middle shoot of the three be considerably weaker than the other two, it may be retained, and nailed in at full length, which probably will furnish a fruit or two, while the other two are providing a farther necessary supply of wood; but if it is a strong shoot, cut it clean away.

If the tree is furnished with four shoots, two on each side, retain them all, and shorten them from ten to fifteen inches, according to their strength, as above, and nail them equally to the right and left.

And if there are five shoots, and that those on the sides are strong, and the middle one weak, shorten the former as above, and lay them horizontally, and nail in the middle one entire; but if the latter is nearly of equal strength, or stronger than the others, cut it clean

clean out, which, if left, would draw the principal part of the nourishment, and impoverish those of the two sides, which should now be wholly attended to, for the middle will always furnish itself in due time.

One fundamental rule to be observed, is, that your tree, at this period of growth, should, if possible, proceed with shoots of an equal strength and number on each side, and depends principally upon two or four good branches, shortened and trained equally to the right and left, in a nearly horizontal direction, which will not fail in their turn to furnish you with more to occupy the wall upward. See WALL-TREES.

Second Year's Pruning.] The trees having had their first year's pruning, observe the following rules in their second year's culture.

During summer, all shoots that arise from the upper and under side of the former year's horizontals, are now to be retained and trained entire, and all buds or shoots that proceed immediately from the front and back part of the said horizontals, should be constantly rubbed off (see *Rubbing off the Buds*), because they cannot be trained consistent with the necessary form and regularity of the tree, having particular regard, however, to reserve all the regular shoots, and train them in at full length; for, except in some particular instances, the shoots must not be shortened in summer, therefore continue them to the wall entire till the winter pruning.

In November, when the leaves are fallen, or any time betwixt that and the beginning of March, you may proceed to the second winter pruning; in performing this, we, for example, will suppose the tree in the first pruning to have been trained with four horizontals, that is, two on each side, and that each of these produced two or three well-placed shoots the preceding summer, or as many as to make the tree now possessed of eight, ten, or twelve branches; now, if these stand four, five, or six on one side, and as many on the other, it is a happy uniformity, and all of which are to be retained, and that to procure still a farther supply of horizontals, each of the above are now to be shortened according to its strength; if they are weakly, cut them to six or eight inches, and if of middling growth to ten or twelve, and if very strong ones to about fifteen or eighteen inches, and train them to the wall horizontally, at six inches distance, observing that the opposite branches of each side range exactly in an equal position.

But where it happens that there are an unequal number of shoots, as for instance, four, five, or six on one side, and seven, eight, or more on the other, and that they are all of tolerable strength; then, to render both sides nearly equal, some of the weakest and worst placed on the fullest side should be cut out.

Observe to proceed as near as possible with an equal number and strength of horizontals in both sides, extending the lowest branches the longest, and if you have now five, six, or eight on a side, trained at five or six inches distance, your tree will begin to assume a handsome form, and next summer you may expect some fruit.

Observations on the general Pruning of these Trees.

Having in the preceding head exhibited the manner of pruning and training, to give the trees their necessary form, and the conducting them to a bearing state, we now come to illustrate the method of general pruning.

The general pruning is performed twice every year, i. e. summer and winter. See their *General Summer and Winter Pruning*.

Previous to the general pruning, observe, that Peaches and Nectarine-trees always produce their fruit upon the one year old shoots, that is, the shoots produced each summer bear the succeeding year, and the same individual shoots rarely bear but once, nor do they furnish good bearing wood after the first year, so that the grand article in pruning, is to procure an annual succession of these young shoots in every part, from the very bottom to the extremity every way of the tree, which are to be obtained principally by shortening, in winter pruning, those of every year, whereby they furnish, at the same time, both a proper crop of fruit, and supply of bearing wood.

The great art in pruning and training a Peach and Nectarine-tree against walls, is to preserve uniformity in every part from the beginning, having strict regard that both sides to the right and left advance with equal strength, and number of horizontals, whose numbers on each side should be equally increased every year, and those trained constantly in a nearly horizontal position, see WALL-TREES, at five or six inches distance one above another, till by degrees they cover the whole space of walling allotted for them, both in breadth and height; for this is very essentially to be observed.

After the tree is thus formed and conducted

ducted to a bearing state, its duration, beauty, and fruitfulness depends wholly upon proper pruning every summer and winter.

The general summer pruning consists in reforming the irregularity of the numerous shoots then produced, and training to the wall at full length, in every part, all regularly placed ones, as succession-wood for next year's bearing, for the great art is to procure a due supply of these every summer in all parts of the tree.

And the general winter pruning comprehends a general reform among all the branches and shoots of all ages, sizes, and situation, such as the retrenching all worn-out and naked branches, as they from time to time occur to make room for those that furnish the best bearing-wood, shoots of the preceding summer; at the same time selecting and retaining in every part the best of the said shoots for next summer's bearing, cutting out unnecessary and irregular ones, and all useless shoots in general, as well as part of the former year's horizontals, to make due room to train the proper useful shoots; all of which should be shortened, to promote their emitting laterals in summer for bearing the year after, and the whole then nailed close to the wall in regular order.

Of the General Summer Pruning.

The time to begin the summer pruning is in May or June. Every one knows that in spring a Peach-tree abounds with a great number of shoots, arising from every side of the last year's horizontals or present bearers, probably three times more than are useful, or than are wanted, or can possibly be trained in without confusion; you must therefore thin them, and ease the tree of all that are irregular, and such that are evidently useless and superfluous, at the same time retaining a sufficiency of the regular shoots, that is, two, three, or four of the side ones upon each horizontal, to be trained for next year's bearing.

The rule is this: each of the last year's horizontals will probably produce from three to six, or more shoots, and of these, some proceed from the upper and under sides, and some from the back and fore parts; those of the former situation, i. e. from the upper and under sides, are to be regarded as the only proper regular shoots, and are to be principally attended to, retained, and trained in at full length, to prune upon in winter for bearing the succeeding year; but those that proceed directly foreright from the front, and those

from the back of the horizontals, or from any of the other parts of the tree in that irregular direction, must be rubbed off close, because, by their situation on the branches, they cannot be trained with due regularity; therefore, that though good of themselves, they are to be deemed irregular, or useless shoots, and should be every where displaced, except in cases where horizontals furnish no other, when the best placed of them may be retained.

In respect to the regular shoots above described, examine, as you go on, their situation and number upon each horizontal; if two or more shoots rise from the same eye, retain only one of them; and if the tree is but a moderate shooter, it is necessary to disburthen it of all that are evidently superfluous, which are such shoots that, though good and well placed, yet if there are four, five, or more on a horizontal, where only one or two is apparently necessary for next year's bearing, some of the weakest and worst placed, or any remarkably luxuriant ones should be cleared away, retaining however, where practicable, always two of the best situated and fairest shoots upon the weak, and three or four on each of the middling and strong horizontals, which, though double, or even treble of what will be apparently wanted, it is eligible culture to reserve enough to chuse from in winter pruning, training the whole at full length during summer.

But where a tree shoots very vigorously in general, I would advise to reserve as many of the side-shoots of each horizontal as there are tolerable room to train at full length, which, by dividing the sap among many, checks luxuriance, which would probably take place in a smaller number, for the natural inclination of these sort of trees should, in some degree, be followed.

Another circumstance to be attended to in thinning and regulating the shoots, is to leave one good shoot at, or as near the end of each bearing horizontal as possible, that it may draw the sap through the whole branch to the nourishment of the fruit.

All weak shoots rising from the old wood must be displaced, unless any regular placed ones appear useful to fill a vacancy.

If any remarkably vigorous or luxuriant shoot arise either from the bearing horizontals, or any of the older branches, examine its situation and strength, and consider whether it is wanted; if it is likely to impoverish the

the neighbouring shoots of moderate growth, or that it is not immediately wanted to fill a vacancy, cut it out; but if useful, either to fill a vacancy, or to prevent an apparent one, or to exhaust too abundant sap, retain it, and pinch it in May or early in June to four or five eyes, and you will procure one middling shoot from each eye the same year, to train in, to chuse from in the winter pruning.

All those very rank or luxuriant shoots, distinguished singularly from the generality of the others of the same tree, by their extraordinary size, green colour, and often redness at the tips, should be cut out from every part, unless you have no other resource to fill a vacancy, when such that are duly placed for that purpose may be reserved and pinched as above observed.

Attention should always be had to the bottom or lower part of the trees, especially those that are aged; if any strong shoot arise in those parts, you must preserve it carefully to succeed worn-out or naked branches, which are cut away by degrees, and if there is a present vacancy, pinch it early in June to four or five eyes, to furnish lateral shoots the same year, to be ready against the winter pruning.

Where a vacancy or want of wood is discovered, at this time, in any part, and that there is only one shoot where two, three, or more are necessary, shorten or pinch the said shoot to three, four, or five eyes, in May or early in June, and it will afford as many laterals the same year to fill the vacant space.

In the whole operation of summer pruning, observe, that all the regular shoots you judge necessary to retain to prune upon in winter, must be left entire, shortening none now, except in cases of vacancy as above, and all irregular and other useless shoots that are now to be taken out, must be rubbed or cut off as close as possible, leaving no stumps, which would shoot out from every eye, and fill the tree with innumerable useless shoots, and choak up and darken the fruit, and deprive it of the necessary benefit of sun, air, showers, &c. and which would require much time to cut out in the winter pruning.

It is necessary to observe, that if the above operations are begun early in summer, the shoots that are to be displaced, may readily be rubbed off with the thumb; but observe, if you delay the work till the wood begins to

harden, they will not break off easily without damaging the mother-branch, therefore use the knife, and cut them as close as possible.

After the above regulations, let all the remaining shoots, when of due length, be trained close to the wall unshortened, and as their ends advance, continue to train them still along at full length, and which are to remain entire until the winter pruning; for in the common course the shoots must never be shortened in summer.

These are nearly all the directions we have to advance relative to the summer pruning, the utility of which, if the operation is performed in due time, is very great both to the tree and fruit.

Therefore, if the operations are begun in May, only just rub off all the ill-placed buds, that is, foreright ones, and those behind the bearing horizontals, and such others that are evidently useless, as formerly observed; and in June, when the useful or regular shoots are of proper length, they are easily and expeditiously trained in, for every one points to its proper place; besides, when the work is begun early, it can be performed with considerably more expedition and truth, as the useless buds or shoots may then, with the utmost facility, be rubbed off close with the thumb, without the use of any instrument, and the early operation will contribute very considerably to the size and goodness of the fruit, as well as beauty and duration of the trees.

The work however should never be delayed longer than the beginning of June, or till the shoots have attained due length for training in, and not, as is often the case, wait till they are two or three feet in length, and form such a thicket and confusion, that the most expert pruner would be at a loss to know where to begin to break through such obscurity, to determine what is necessary to be done, which, besides, is highly prejudicial to the prosperity of the fruit, the main object, as well as to the beauty and duration of the tree; and the confusion occasioned by such a thicket of wood and leaves prevents you from cutting close, and the tree becomes full of disagreeable stumps, producing useless shoots from every eye, which take up much time to remove in the winter pruning, and upon the whole the fruit being hidden, choaked up, and as it were buried behind such a thicket, becomes tender, as is evident from the colour, which
scorch-

is rather white than green, and when thus suddenly laid open to the air, joined to a scorching sun, great part of it withers and drops off, which never happens when the fruit has from the beginning been inured to the weather, by early rubbing off the useless, and training close the useful shoots, so as to give the sun and air free admission; but on the contrary the fruit always excels in size, colour, and flavour.

At this time of laying in, or dressing, i. e. June, we recommend the following observation, which could not be so discoverable at the earlier dressing, viz.

Where short shoots, of an inch or two in length, appear upon this or the former year's horizontals, or sides of the old wood, and that they apparently will not exceed that length, it is of utility to reserve them, at least till the winter pruning, because they may prove natural fruit-spurs, which, at that season, is distinguishable by having a cluster of blossom buds. See the *Winter Pruning*.

If a vacancy is any where discovered early in summer, you may pinch some of the strongest neighbouring shoots to three or four eyes, and they will furnish you shoots the same year, to chuse from in the winter pruning. See *Pinching the Shoots*.

Do not pull off any of the leaves at this time, as often practised, with a view to admit the sun, for these are necessary to the growth, both of the young shoots and fruit, so should never be taken away, unless there is indeed in any part so great a thicket as to darken the fruit considerably, when a little thinning may be necessary; in other cases that work must be dispensed with till the fruit are full grown.

After the trees have been summer-dressed, according to the preceding directions, you must not forget to review them once a fortnight, to rub off any unnecessary or straggling shoots that may arise, which is soon done, and to fasten up any shoot that may start from its place, or project from the wall, as well as to continue the trained shoots in general thereto, as they advance in length.

One thing more, which is necessary to observe in the summer dressing, is the blight which attacks these trees: this disorder is the effect of noxious winds, that occasion the curling up of the leaves, which become thick, clammy, yellowish, red, and scabby; and attacks the ends of the shoots, and proves very injurious both to the young shoots and fruit, and often their destruction; for the blighted leaves ex-

haust the sap, at the expence of all the other parts of the tree. When your trees are first attacked, there is no other remedy for this accident than to pick off all the curled leaves as soon as discoverable, and also cut off, below the disorder, all the infected part of the shoots, which generally form a rough disagreeable bush or thicket; this enables the sap to push out new shoots lower down, for next year's bearing. So destructive is this infection, that it frequently destroys in a short time the whole leaves of a wall of trees; and when these are gone, the principal part of the fruit soon after follow, which generally withers and drops, as likewise the young wood, for next year's bearing, either dies or becomes stunted. Various other methods have been tried to prevent the spreading of this pestilence, but nothing effectual.

Insects also often prove very injurious to these trees; a fumigating engine lately invented is recommended, in which is burned tobacco, the smoke of which issuing with a perpetual stream, is applied to the trees attacked by the vermin, which infallibly destroys them, without injury to the trees or fruit. See FUMIGATION, INSECTS, &c.

Of the General Winter Pruning, &c.

The winter pruning may be executed any time from the fall of the leaf in November, until the beginning of March; for no weather has any particular effect with regard to proving injurious to the new-cut shoots, as sometimes imagined.

This work however should never be delayed till late in spring, because the blossom buds will be so very turgid or swelled, that numbers of them will be unavoidably rubbed off in performing the operation of pruning and nailing; though some wait till this period, that they may better judge of the good or bad buds, and of the wood-buds from those that produce blossom and fruit. This is of some importance, but the sap is generally risen sufficiently in January, or sooner, to swell the buds, to enable you to distinguish them.

As these trees always bear their fruit upon the one year old wood; that is, the shoots produced each summer bear the fruit the summer following, so that the fruit-buds are principally to be looked for upon these shoots.

Wood-buds are distinguishable by their being long and firm; blossom or fruit-buds are round, swelling, thick, and soft.

It must be observed that good blossom buds are always double, two at an eye, having a

leaf-bud or shoot between them; those that are single, though they sometimes have a leaf-bud, and blow pretty well, never set fruit so freely as the twin blossoms.

Great attention must always be had to keep every part of the tree well furnished with an annual supply of young wood, of the former summer, for bearing next year, advancing, as it were, gradually one behind another, from the bottom to the extremity every way; which is easily acquired by properly selecting, thinning, and shortening those of every year, and by cutting out annually some of the old horizontals to make room for them. Likewise observe, that as the bottom of the trees are apt to become naked, be also watchful of that part, to retain in proper places an annual supply of strong young wood, either to fill an immediate vacancy, or to be trained up gradually to supply the place of any naked or worn-out branch, that may happen either there, in the middle, or upper part; which are such that support little or no young wood, or produce weak and a scanty portion of shoots, and should, wherever they appear, be cut down to the great branch from which they proceed, or to any lower strong young shoot they support, or to any convenient branch supporting such shoots: and part of the old horizontals must always be cut out annually, to make room to train in the bearing wood.

Previous to the performing the operation of winter pruning, it is eligible to unnailed the greater part of the branches, and all the young shoots in general; you then have full liberty to examine the state and situation of the whole, as well as to have due command in using your knife, and nailing the tree again in regular order, according to the situation and strength of the general supply of young shoots necessary to be retained for next summer's bearing, &c.

The trees being unnailed as above, you should first proceed to examine all the principal branches, and see if any are become naked, or worn out. Naked branches are such that, as formerly hinted, have advanced a considerable length, and support very little or no good bearing shoots, or lateral branches furnished with such wood, and should be cut out to their origin, provided there are proper young wood, or horizontals, well furnished with such shoots, properly situated to be trained up to supply their places; for way must always be made for those branches that furnish the best young wood, both for bearing the following summer, and providing a further

supply of shoots for future service. And the worn-out branches are easily distinguished by their uncommonly weak shooting, so should be cut out as above, to make room to extend those of better growth, as just observed.

From these you pass to regulate the shoots of the year; of which you will find often, on the same tree, weak ones, middle-sized ones, and some of very luxuriant growth; those of the middle size are to be principally attended to; observing, as noticed in the summer pruning, that the proper shoots for our present purpose to train for next summer's bearing, are principally those that grow upon the one year old horizontals, and of which we are now to select and retain the most regular placed ones, i. e. such that are the most properly situated for training close and neatly to the wall, which are chiefly those that proceed from the two sides of the said horizontals, so that keeping those in view for training, clear away all the irregular and other useless shoots, as hereunder mentioned.

Suppose your tree to be chiefly of moderate growth, and here and there in it shoots of superior luxuriance and rankness; these, wherever situated, must be cut out close: but if the tree is in general vigorous or luxuriant, the shoots must only be thinned in a moderate way, as hereafter directed.

All shoots of extreme weakness should be cut away, unless you shall see it necessary to keep one here and there to fill a vacancy, or as a reserve in case of one the future year, in which latter case I would cut them down to an eye or two.

I do not comprehend by weak shoots those short ones an inch or two long, which I call natural fruit-spurs, and often furnish excellent fruit, and must be retained.

All foreright shoots, and such that proceed directly from the back of the branches, and in other irregular directions, that cannot be trained consistent with the uniformity of the tree, and those arising from the old wood, are also to be cut off close, except in cases of vacancy, and that there is no other resource.

Cut away all stumps of last summer, and leave none now, cutting every thing close.

During the whole operation of the above reforms, great attention must be observed in selecting and retaining all the well-placed regular side-shoots above described, which must next be regulated according to the following rules.

Having in this manner cleared your tree from worn-out branches, and from luxuriant, irregular,

irregular, and other bad shoots, there is nothing left but useful branches supporting horizontals, furnished with proper young wood, nearly of equal strength, and you see your work clear; you have nothing now to do but select and retain upon each horizontal a due portion of the best placed of these proper shoots, and retrench the superfluous ones.

Examine therefore the number of proper shoots upon each horizontal, and their strength, keeping in mind, that the middling strong ones are to be principally attended to. We advised in the summer pruning to leave upon each horizontal two, three, or four shoots, according to the strength of the tree in general: now, if your tree is fully trained, no more than one or two, as you shall see necessary, need be left upon each horizontal, except in cases where a tree is very luxuriant, or where there is a very wide space to fill, or a vacancy in its neighbourhood; but if the tree is still in training, you may retain two or more shoots upon each bearer, as you shall judge expedient, to forward the tree to its intended form. But suppose you are upon a full trained tree, or such that are nearly so, and that you judge one of the young shoots on each horizontal is sufficient, keeping in view they should be trained about five, six, or seven inches distance; on this consideration you are to select the best of the lowermost of these shoots, unless you shall judge necessary to advance the length of the branch; then chuse the best of the uppermost, observing that whatsoever shoot you fix upon, to cut off the upper part of the horizontal on which it stands, close to the said shoot, or if you leave two or more shoots upon each horizontal, let one be near the upper, and the other near the lower part thereof, on the opposite sides, and cut down the horizontal to the uppermost of the two shoots, so that by cutting away part of each of the former year's horizontal, the remaining part is terminated by a young shoot, which now commences the bearer or horizontal of the ensuing year.

Observe, where two or more shoots arise from the same eye, never leave but one.

Where any shoots rise from the sides of the old wood or main branches, and which you shall judge necessary to retain, either to fill a present vacancy, or to be ready for an apparent one, it may be reserved without shortening down the said branch to it, as is necessary in the one year's horizontals, unless that part of the said branch immediately from the shoot upward is naked, or unfur-

nished with young wood, in which case take it down to the shoot in question.

Those short shoots or natural spurs, an inch or two long, above observed, may be retained wherever they appear, for they are generally well furnished with blossom buds.

Observe, that many of the principal bearing shoots which you now retain, will have probably put out several small twigs or side shoots; these, being produced late, are generally spongy, besides being superfluous or unnecessary, must be cut close, leaving only the main shoot.

In cutting out the irregular and superfluous wood in general, cut all close, leaving no stump, which would send out shoots from every eye the ensuing summer, and crowd your tree with useless wood; and any of those short natural spurs of the former year, now devoid of blossom buds, or that exceed two or three inches in length, should now also be cut away close, but especially such that advance directly foreright.

After making these reforms of regulating and thinning, we proceed to consider of shortening the remaining select shoots, the utility of which is obvious; for as these trees always produce their fruit upon the one year old shoots, the same wood, by proper shortening in winter pruning, furnishes, as well as fruit, lateral shoots the following summer, to bear the fruit the year after that; therefore, to procure an annual supply of young wood in the proper parts, we must not omit stopping or shortening that of each year in the winter pruning, by which each shoot will emit two, three, or more lateral ones the succeeding summer; whereas, if they were left at full length, the sap which would have thrown out shoots below, would mount to the extremities, and leave the bottom bare, and in a short time all the lower part of the tree would become naked, and furnished with bearing wood only towards the extreme parts. The rule of shortening is this; if the tree is in health, and of a middling free growth, shorten or cut off about one third of the length of each shoot; for instance, shoots of ten or twelve inches should be shortened to six or eight; those of about fifteen or eighteen inches shorten to eight, ten, or twelve; and so in proportion to the length and substance of the respective shoots, observing, where a tree is weak, or on the decline, and makes weakly shoots, to leave the shoots thin, and cut them shorter in proportion: on the contrary, where a tree is in general a vigorous shooter, leave the shoots close,

close, and shorten them moderately, that by retaining a good deal of wood to divide and exhaust the great redundancy of sap, is the only means to reduce a luxuriant tree to a state of moderate growth, and to bear plentifully.

In shortening these shoots, it is of importance to cut them just above a wood, or branch-bud, that it may produce a shoot for a leader, to draw the sap through the whole horizontal, the more effectually to nourish its respective fruit. A wood-bud is with facility distinguished from a blossom-bud, the former is long, narrow, and firm, the blossom-buds are roundish, thick, swelling, and soft; so that by cutting to a wood-bud you are sure of a leading shoot, and the fruit will be well-nourished; but where two blossom-buds appear on the same eye, a wood-bud also generally issues from between, so that if you cannot conveniently cut to a wood-bud, make the cut to a twin blossom-bud as above.

Thus much for the general directions to be observed in the principal winter pruning, although there are other circumstances that cannot be conveyed by words, nor judged of but upon the spot, and depends chiefly upon practice.

We will however subjoin a few other particulars very necessary to be observed.

In the course of practice, you will meet with trees of very different habits of growth; some, for instance, are weakly, and produce small or weak shoots; others are of a middling state, shoot freely in every part, but not too vigorous, which is the most desirable state of growth of any; and some shoot very vigorous in almost every part. With respect to the former, if the tree makes very weak shoots, examine whether the disease is at the root, if it is, pull it up; if not, preserve it, and dig in rotten dung, which often recovers these sort of trees, observing to keep it thin of wood, and prune the shoots short, even the best to five or six inches, till it recovers. In the second case, the middling shooting tree is to be managed as in the general directions. And in the third instance, if the tree is remarkably vigorous, and bear little, it should in some degree be humoured in its own way; for if you cut out many, and shorten considerably the remainder of these very vigorous shoots, where they are general, as is frequently done without mercy, supposing by that practice to check luxuriance, and so continue to prune, and depend entirely upon the smallest ones, the consequence is,

that by much thinning, and close cutting vigorous trees, they continue to shoot still with greater vigour and irregularity for several years, without being able to gain either form or fruit, till at last, by severe pruning, they pass into the opposite extreme, become, as it were, tired with acting ineffectually, grow very weak and sickly, and shoot no more. On the contrary, by following, in some degree, the inclination of the tree, and leave the shoots as close as there are any tolerable room to lay them in, and shorten them very little, some of the strongest not at all; and by thus leaving a good deal of wood, and that at a considerable length, the sap is divided, and the luxuriance is checked; and in a year or two your tree will become a moderate shooter, and furnish fine young wood, and bear plentifully.

The Method of Nailing them.

The trees being pruned, they should be directly nailed to the wall; this however should always be done as you go on, that is, as soon as one tree is pruned let that be nailed before you prune another.

This operation is sufficiently explained under the article WALL-TREES and NAILING: we shall just observe, that as your trees having, previous to the pruning, been entirely unnailed, you have the opportunity of nailing the whole with the greatest regularity, observing to bring the lowermost branches on each side down horizontally, and train them along perfectly strait, and so much horizontal, that the extremities be but a few inches higher than the bottom: nail them close, proceeding in the same manner with the next immediately above them; and so of all the rest, making the opposite principal or mother-branches on each side, range nearly in the same position, preserving on each side an equilibrium of number and strength, observing nearly the same of their respective horizontals or bearers, training them strait and regular, at five or six inches distance from one another, observing if the pruner has left in any place more wood than can consistently be new laid in; the nailer must regulate that according to his discretion, by either cutting out entirely such superfluous or unnecessary shoots, or take it down to one eye to furnish a shoot for another year, if he shall judge it of utility.

Of defending the Blossoms.

Peach-trees come into blossom early in spring, when cutting frosts prevail, which, in

in some seasons, is so severe as to cut off the whole. Not only the blossom is liable to this disaster, but also the young fruit, till they are as large as ordinary cherries, which oblige us to have recourse to all possible means to defend them.

The dangerous time lasts a month or six weeks; various ways have been tried to shield the trees during that period; some cover with large garden mats, which I have often found of great use; but where there are much walling, it takes up much time to cover and uncover, as the danger threatens, for they must only be used when there is apparent danger: free air and light must be admitted, so that if the mats are nailed up in an evening when there is an appearance of a cutting frost, they should be removed again in the morning, if the weather is quite mild; but if not, they may be permitted to remain till it is: do not omit however to take them down when the weather changes; and so continue their use only occasionally, till your fruit are as big as large peas at least.

This is the principal expedient in practice to defend these trees, which, after all, it sometimes does not secure us a quarter of a crop; it however should not be omitted in hazardous times, especially to some of the early and choice sorts. See COVERING TREES.

There is another method which I have sometimes experienced to save a few fruit, when all that have been fully exposed was cut off; this is to procure a quantity of cuttings from the branches of evergreen trees, such as those of laurel, yew, spruce-fir, &c. and stick them moderately thick between the branches of the Peach-tree, so as the leaves of the cuttings cover the blossom; these should be placed when the blossoms begin to open, not too thick to darken it, and may be permitted to remain until the beginning of May, when the fruit will be set, and past danger. In default of the above cuttings, I have used branches of dried fern.

Neither of these methods of covering, nor indeed any other can we recommend as generally effectual; but a poor expedient is better than none; they often insure a few fruit, when those that are fully exposed are all destroyed by the frost.

Thinning the Fruit.

In favourable seasons Peach and Nectarine-trees sometimes set their fruit very thick in every part, often double or treble the quantity that have room to grow, or the trees capable

of nourishing, and frequently the fruit are set only here and there in clusters; in either case they must be thinned, otherwise the fruit will not attain half its common size, and during their growth would thrust one another off; besides, if the trees are overloaded, they would produce but very weakly shoots for next year's bearing, and would be two years before they recovered themselves.

This work should be performed when the fruit have attained nearly the size of small cherries, which will be about the beginning or middle of May, for if you thin them sooner, frosts may destroy the remainder, and you have no resource left.

The rule of thinning is, if the tree is weak the fruit must be left thin, not more than one or two on the larger shoots, and none upon the small ones, which is the only way to insure wood for another year: upon trees of a middling strong growth you should retain but one fruit upon the smaller shoots, and two upon the middling sized ones, and three upon the strong shoots: but the smallest kinds of fruit may be left a little thicker in proportion, and the large sorts should be thinner, i. e. about six inches distance upon each shoot, and the largest of all eight or ten. In performing this work, observe to select and retain the best placed, largest, and fairest fruit, in every part, according to the above rule; and in removing the superabundant ones, be careful not to disturb these. Leave no where two or more upon the same eye, especially if one exceeds the other in size, taking off the smallest, which the other would starve; but if they are of equal size, you may, if it shall seem necessary, leave both of them.

We formerly observed, that it was of utility to preserve a slight coverture of the leaves of the tree, by way of shade to the fruit during their growth, and until they begin to change colour: when they have attained that state of perfection, it is necessary to pinch off a few of the leaves that immediately cover the fruit, to admit the sun to give it colour and flavour.

Do this however regularly, and thin the leaves by degrees, which should be pinched, and not torn off, which would mangle the eyes, and prevent the fruit buds from forming themselves for next year.

General Observations.

Peach-trees, from the time of heading down to the sixth or seventh year, may be
said

said to be in a state of training, though they frequently begin to bear the second or third year after the operation of heading down; and in five, six, or seven years will bear pretty plentifully, according to their size, for they will not have attained their full growth till they are ten, twelve, or fifteen years old, according to the extent of walling they have to cover, at which age they will be arrived at the beginning of their ultimate state of vigour and perfection of bearing, which they generally acquire between the seventh and fifteenth year, and in which they will continue for twenty or thirty years to come; for these trees, with due management, will endure fifty or sixty years, provided no accidents happen, such as violent blights, or tainted with gum, or attacked by vermin; so that the opinion of some, that Peach-trees are seldom of more than twelve or fifteen years duration, is erroneous, and must be given up, for it is owing only to bad management that they do not last as long as other fruit-trees.

The trees may be said to be in their third state when they begin to decline through age; but if our general directions in pruning are observed, this seldom happens until they are upwards of thirty or forty years old, when they should be cherished by leaving only the best young shoots, and that moderately thin, and which should be pruned shorter than the general rules, and make the most of strong young wood that rise from or near the bottom, to supply the place of worn-out branches.

When it is observed any trees approach near their end, and the bottom of the walls become naked, young trees should be planted in due time in the spaces between the old ones to succeed them, and as they shoot up lop off the lower branches of the old trees, which in four or five years may be taken entirely away; thus you may keep your walls always occupied, without intermission.

It sometimes happens that the trees do not bear fruit of the approved or desired sort, which is often the mortifying circumstance when purchased in some nurseries, and a very cruel one, after all the trouble of training, &c. To remedy this, you, in August, may bud some of the young shoots of the same year, in different parts of the tree, and as these advance cut the other parts away, and in two or three years they will spread considerably, and bear fruit.

If the gum has attacked any shoot of a tree, young or old, cut it off an inch below, to stop

the communication, and prevent killing the whole shoot.

The utility of tillage to these trees is very obvious, and should be performed every autumn and spring.

Dung, in moderation, is also of utmost utility in preserving due vigour and health in these trees, and to promote the size of the fruit; let it be perfectly rotten, and added every two or three years, spreading it all over the border, and dig it in in the usual way.

As to cultivating kitchen herbage on the borders, the moderate growing sorts, such as radishes, lettuce, small salad herbs, kidney-beans, a few small early mazagan beans, peas, &c. do very little or no injury to the trees.

Peach and Nectarine-trees are often planted in forcing-frames and hot-walls, to produce early fruit; the sorts proper for this are the earliest kinds: for the method of performing it, see *FORCING FRAMES* and *HOT-WALLS*.

Of planting these Trees for Ornament.

There are two varieties of Peach-trees that are esteemed chiefly by way of curiosity and ornament, which we judge it most proper to speak of under a separate head. These are, the

Double blossomed Peach-tree.—**Dwarf Peach-tree.**

The former of these has great beauty in its double flowers; it attains the height of common Peach-trees, and differs in nothing from them but in the doubleness of its flowers, which, like those of the others, are succeeded by fruit: the tree makes a fine appearance in ornamental plantations.

The Dwarf Peach rises but two or three feet high; the stem is small, and hath very slender branches, which produce small insipid fruit, the size of a nutmeg. It is sometimes planted in pots, and brought to table with the fruit upon for curiosity, and makes a singular appearance.

For purposes of ornament, any of the sorts of Peach-trees may, with propriety, be admitted as standards in the shrubbery, and will make a fine appearance when in bloom, and if they stand in a sheltered situation, there will be a chance of having now and then some fruit from them: they may either be planted as standard-dwarfs, or as half or common standards.

The propagation of the Double Blossomed and Dwarf kind is effected by budding the same as common Peach trees.

Third

Third Division of Amygdalus.

AMYGDALUS-NUCIPERSICA, the Nectarine-Tree. *Abrikose*

Class, order, and characters the same as the Amygdalus.

The Nectarine and Peach-trees have been generally considered as distinct species, principally by the difference of their fruit; but late discoveries has determined otherwise, and that they are found to be varieties of one another, but which is the original is not yet agreed on; but certain it is, that there have been instances of Nectarines growing naturally on Peach-trees, accompanied by Peaches on the same branch; which very singular phenomenon determines them to be varieties of one species.

Neither the trees, by their manner of growth, the wood, leaves, nor flowers of Nectarines and Peaches, can with any precision be distinguished from one another; but the fruit is distinguishable at sight in all its stages of growth: that of the Nectarine hath a smooth firm skin or rind, and the Peach is covered with a soft downy matter; the flesh too or pulp of the Nectarine is considerably firmer than that of Peaches.

Their temperature and general culture is the same in every respect.

However, as they are generally considered as different fruit; we, for distinction sake, range them in separate divisions, though all under the principal genus Amygdalus.

The varieties of Nectarines that merit esteem are,

¹*Fairchild's early Nectarine.*] A small round Nectarine, of a bright red on one side, the other yellow; ripe beginning or middle of August.

²*Violet Nectarine*] A middle-sized fruit, purple on one side, the other of a yellowish green, tinged with red; ripe latter end of August.

³*Elrouge Nectarine.*] A middle-sized longish Nectarine, purple or dark red on one side, the other yellow, and the rind becomes shrivelled, and the pulp separates from the stone; ripe end of August.

⁴*Newington Nectarine.*] A large beautiful Nectarine, being of a fine scarlet or bright red on one side, the other changing gradually to a bright yellow, and adheres to the stone; ripe beginning or middle of September.

⁵*Red Roman Nectarine.*] A fine large, round, dark red Nectarine, assuming a yellowish hue on one side, the whole becomes

somewhat shrivelled, and adheres to the stone; ripe middle of September.

⁶*Temple's Nectarine.*] A middle-sized longish Nectarine, pale red on the sunny side, the other a yellowish green, and separates from the stone; ripe middle of September.

⁷*Tawney Nectarine.*] A middle-sized roundish fruit, of tawney red on one side, the other a dusky yellow, and adheres to the stone; ripe in September.

⁸*Scarlet Nectarine.*] A middle-sized, wholly red, beautiful Nectarine, the sunny side being scarlet, the other a pale red colour, and adheres to the stone; ripe beginning and middle of September.

⁹*Brugnon or Italian Nectarine.*] A large fruit, deeply reddened next the sun, and yellowish on the other side, and adheres to the stone; ripe in September.

¹⁰*Golden Nectarine.*] A middle-sized round Nectarine, faintly reddened on the sunny side, the other parts are of a golden yellow, and adheres to the stone; ripe late in September.

¹¹*Murphy Nectarine.*] A middle-sized fruit, of a dusky purplish red on one side, the other a yellowish green, and adheres to the stone; ripe beginning or middle of September.

¹²*Virmash, or Peterborough Nectarine.*] A middle-sized, round, greenish Nectarine; ripe middle or end of October.

Of the above twelve varieties of Nectarines, if you would cultivate only the best, I should advise to plant the following. Fairchild's Nectarine claims a place for its early perfection. The Violet and Elrouge Nectarines are pretty fruit, ripen freely, and their flavour is rich and vinous. The Newington and Roman are the largest, most beautiful, and best flavoured Nectarines in the world. Temple's Nectarine is also a very good fruit, and is well esteemed; and the Virmash or Peterborough Nectarine merits a place in the collection, because it ripens late, and furnishes a variety for the desert after all the others are gone.

The Nectarine-tree is in temperature and manner of growth, in every respect, like the Peach, and like that tree requires to be trained against the walls, and in the same aspect and soil.

Its propagation also, and whole management in all its stages of growth, is the very same as the Peach-tree.

Therefore, to avoid unnecessary repetition, the reader is requested to turn to the *Amygdalus-Perfica*, or Peach-tree, for the method of

of propagation, planting, pruning, and every other article of culture, where an ample direction, equally applicable to the peach and Nectarine, is given.

ANACARDIUM, Acajou, or Cashew-Nut.

There is but one species; it is of the tree kind, a native of both Indies, and retained here in stoves for curiosity.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, five sharp-pointed deciduous leaves. **COROLLA**, five long, narrow, reflexed petals. **STAMINA**, ten short filaments, and roundish antheræ. **PISTILLUM**, a roundish germen, inflexed style, and oblique stigma. **PERICARPIUM** none, the receptacle becomes a large round pulpy substance, crowned by a kidney-shaped nut.

There being but one species, it is named simply *Anacardium*.

This tree appears as a small shrub here in our stoves; but in the Indies it rises twenty feet in height, dividing into spreading irregular branches, decorated with large oval leaves, and small white flowers in umbels at the ends of the shoots, succeeded by a large yellow pulpy receptacle, crowned by the fruit, which is a kidney-shaped nut, an inch long, containing an eatable sweet kernel, very palatable when roasted.

The propagation of this plant is by planting the nuts, which are brought hither annually by the West India ships.

They are to be planted singly in small pots, and plunged in the bark-bed, and the plants will appear in a month; continue them always in the stove.

ANAGALLIS, Pimpernel.

The plants are herbaceous, one of which is the common trailing annual Pimpernel, a weed of the garden and fields; and one is an erect, small, ornamental perennial of the green-house.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is monophyllous, five-parted, and permanent. **COROLLA** is monopetalous, wheel-shaped, and five-parted. **STAMINA**, five erect short filaments. **PISTILLUM**, a globular germen, simple style, and headed stigma. **PERICARPIUM**, a globular capsule, and many angular seeds.

The species that merit culture is,

ANAGALLIS Monelli.

Monelli, or Perennial Anagallis.] **Anagallis** with erect stalks, and spear-shaped leaves.

This is a low erect perennial, a foot high, somewhat bushy, and closely adorned with leaves, by pairs, or by threes, and numerous wheel-shaped blue flowers on long foot-stalks, which make a pretty appearance.

The propagation of this plant is either by seed on a warm border in April, or by cuttings in the shade in summer, and must be potted and housed in winter; shift them occasionally into larger pots, removing them each shifting with the ball of earth entire about their roots, and give moderate waterings in common with other woody exotics of that department.

ANAGYRIS, Stinking Bean Trefoil.

This genus furnishes two hardy deciduous flowering shrubs, adorned with oval leaves and long spikes of papilionaceous yellow flowers.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, a monophyllous, bell-shaped, five-parted cup. **COROLLA** is papilionaceous, the standard broad and heart-shaped; the wings oblong and plane; and the keel long and erect. **STAMINA**, ten distinct filaments, and simple antheræ. **PISTILLUM**, an oblong germen, simple style, and hairy stigma. **PERICARPIUM**, a large oblong pod, containing kidney-shaped seeds.

The species are,

¹**ANAGYRIS Fœtida**.

Common Stinking Anagyris.] **Anagyris** with oval leaves and spikes of flowers, proceeding from the sides of the branches.

²**ANAGYRIS Creticum**.

Cretan Stinking Anagyris.] **Anagyris** with oblong leaves and longest spike of flowers.

These shrubs rise eight or ten feet in height, decorated with simple, alternate, hoary leaves, and numerous bright yellow butterfly-shaped flowers, disposed in long hanging spikes, arising from the sides of the branches in May and June, but rarely perfect good seeds in England.

They are exotics of Spain, Italy, and the Archipelago Islands, but prosper here in the full ground.

The propagation may be effected both by seed and layers.

The seed is procured from abroad by the nursery-men and seeds-men, which should be sown in a bed of light earth in March, and the plants will appear in May; give occasional waterings in summer, and shelter the first winter from severe frost; in March following plant them out in rows, and in two, three, or four

four years they will be of due size for the shrubbery.

ANANAS, the Pine-Apple. See BRO-MELIA.

ANASTATICA, Rose of Jericho.

This is a very low bushy annual, adorned with oval leaves and small whitish flowers, of four petals, disposed in short spikes.

Class and order, *Tetradynamia Siliculosa*.

This plant has great singularity, which is, that in autumn, when it begins to decay, it contracts itself; and if then taken up and preserved in a dry place till next year, nay for many years, then placed in warm water, it will expand as in its natural growth.

It is raised from seeds in March or April, in a hot-bed, and in May the plants may be potted and placed in the full air; they will flower in June, and, with occasional shelter of a frame, will perfect seeds in autumn.

ANCHUSA, Bugloss.

There are eight or nine species, all of which are herbaceous, chiefly perennial, and of hardy growth; some grow erect, others trail, garnished with rough simple leaves, and monopetalous funnel-shaped flowers, four or five of which merit culture, some as salutiferous medical plants, others for ornament.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is acutely five-parted, and permanent. COROLLA, monopetalous, funnel-shaped, and five-parted at the brim. STAMINA, five short filaments, and incumbent antheræ. PISTILLUM, four germina, a filiforme style, and obtuse stigma. PERICARPIMUM none, the four seeds being lodged in the calix.

The species of most note are,

¹ANCHUSA *Officinalis*.

Common Officinal Bugloss.] Anchusa with erect stalks, spear-shaped leaves, and imbricated spikes of flowers.

Varieties of this.] Common Bugloss with blue flowers.—Common Bugloss with white flowers.—Common Bugloss with red flowers.

²ANCHUSA *Sempervivens*.

Ever-green broad-leaved Bugloss.] Anchusa with trailing branches, broad leaves, two leaves on the pedunculuses, and short spikes of blue flowers.

³ANCHUSA *Orientalis*.

Eastern Yellow Bugloss.] Anchusa with trailing branches, hairy woolly leaves, the branches and flowers growing alternately, and oval bractæ on the spikes between the flowers.

⁴ANCHUSA *Virginiana*.

Virginian small Yellow Bugloss.] Anchusa with a low smooth stalk, and bright yellow flowers, placed in loose spikes.

All these are herbaceous perennials, that prosper in almost any soil and exposure, though they are of longest duration in dry soils.

The two first sorts grow naturally in Britain, but all the others are of foreign growth.

The roots of all the sorts are fibrous.

The stalks and branches are round, thick, and mostly very rough and hairy, decorated with simple, oblong, very rough leaves, placed alternate; and numerous flowers, collected into clusters and spikes, ornament the upper parts, each separate flower formed of one infundibuliforme or funnel-shaped petal, having a long tube below, and a spreading brim, appearing, in the different species, in spring, summer, and autumn, and continue in long succession on the same plant, which, in all the sorts, are succeeded by abundance of seed in autumn.

The *Anchusa Officinalis*, and respective varieties, obtain two feet in height, sending forth many side shoots, and a numerous succession of flowers in June and July.

The Evergreen Bugloss and *Oriental Anchusa* extend their branches upon the ground, which furnish a succession of flowers most of the summer months, and the former often continues in bloom from May till Christmas.

The *Virginian Anchusa* is a very low plant, but is valuable for its producing numerous flowers early in spring.

Uses in Gardens, Propagation, &c.

In respect to their uses in gardens, the Common Bugloss is esteemed principally for its medical properties; but all the varieties may also be employed with the other species as plants of ornament, for the embellishment of the compartments of large gardens, where many plants of easy culture are required; where, though the flowers possess no remarkable beauty, they will appear conspicuous enough to encrease the variety.

All the sorts love a dry soil, for though they grow strongest in moist rich land, yet their duration in such soils is rarely more than two or three years.

The propagation of all the sorts is by seed, in autumn or spring, in a bed of light earth, and in May, June, or July, the plants will be large enough for transplantation into the places where they are finally to remain.

All the sorts rise freely from the scattered or self-sown seeds.

ANDROGYNA *Planta*, (from a man and a woman.) By botanists a plant is termed Androgynous, which produce both male and female flowers on the same root; the cucumber, melon, gourd, &c. and of trees, the oak, platanus, chestnut, walnut, mulberry, birch, hornbeam, hazel, &c. furnish examples. See *Masculus Flos*, &c. Androgynous plants constitute the class *Monoecia* of Linnæus. See **MONOECIA**.

ANDROMEDA.

The plants of this genus are principally of the tree and shrub kind, mostly deciduous, hardy, and of moderate bushy growth, adorned with simple alternate leaves, and small monopetalous bell-shaped flowers, in spikes, or clusters.

Class and order, *Decandria Monogynia*.

Characters] **CALIX** is acutely five-parted, coloured, and permanent. **COROLLA**, one bell-shaped petal, cut into five reflexed segments. **STAMINA**, ten short filaments affixed to the corolla, and two-horned antheræ. **PISTILLUM**, a roundish germen, long permanent style, and obtuse stigma. **PERICARPIMUM**, a pentagonal capsule of five cells, containing many roundish seeds.

The species are,

¹ANDROMEDA *Arborea*.

Tree Andromeda, or Carolina Sorrel-Tree.] Andromeda with oblong, oval, pointed, alternate leaves, roundish-oval greenish flowers, disposed in long naked spikes, proceeding from the sides of the branches.

²ANDROMEDA *Paniculata*.

Paniculate-spiked Virginia Andromeda.] Andromeda with oblong, crenated, alternate leaves, and cylindrical yellowish flowers, in branching naked spikes at the ends of the branches.

³ANDROMEDA *Mariana*.

Maryland Aggregate Andromeda.] Andromeda with oval entire leaves, placed alternate, and greenish flowers, collected in aggregate bunches.

⁴ANDROMEDA *Caliculata*.

Caliculate Box-leaved, Canada Andromeda.] Andromeda with obtuse, spear-shaped, punctured, alternate leaves, and cylindrical white flowers, disposed in short leafy spikes at the ends of the branches.

Variety.] Caliculate oval-leaved, evergreen Andromeda.

⁵ANDROMEDA *Racemosa*.

Racemose-spiked Pennsylvania Andromeda.] Andromeda with oblong serrated leaves, and cylindrical swelling flowers, in clustered bracteal spikes.

These plants are natives of North America, where they grow naturally in marshy or boggy places; the first of which is somewhat impatient of severe frost, but all the others are very hardy, and prosper best in moist situations.

The tree *Andromeda* rises ten or fifteen feet in height, the branches slender and drooping; this is somewhat tender; so some plants should be retained in pots to be sheltered in winter.

The *Andromeda Paniculata* is a shrub of three or four feet stature, and sends forth many branches.

The other three species are low bushy shrubs, rarely exceeding two feet in height.

All these shrubs flower here annually in June and July, but they rarely ripen seed in these parts.

Uses, Propagation, &c.

With respect to the utility of these shrubs in gardens, the first sort is admitted principally among the green-house plants, and delights in moisture; the other sorts may be admitted to encrease the variety in the shrubbery; but they should have a moist soil, otherwise they will not prosper in summer.

The propagation of all the species may be effected by seed, which is imported by the seedsmen annually from America, which must be sown in spring in a bed of moist earth.

They may also be encreased by layers in autumn.

All the shrub kinds may also be propagated by suckers, which they send up pretty plentifully every year from the roots.

ANGIOSPERMIA, the name of the second of the two orders in the class *Didynamia* of Linnæus. See **DIDYNAMIA**.

The essential character of this order is, that the seeds of the respective plants included therein are lodged in a pericarpium, i. e. a vessel or pod, which distinguishes it from the other order *Gymnospermia*, of the same class, where the seeds are placed naked in the bottom of the calix. See **GYMNOSPERMIA**.

ANEMONE, including the *Pulsatilla*, or Pasque-Flower, and the *Hepatica*.

It will seem strange to some to see the *Pulsatilla* and *Hepatica* retained as species of the *Anemone*, which were formerly ranged as distinct genera, but late improvements in botany have proved their general characters to be

be the same, and proclaim them all relations of the same family, and as such we must treat of them, though, as they differ extremely in their general appearance, as also in their culture, we, for distinction sake, will exhibit them in separate divisions, under the generic name *Anemone*. See *ANEMONE-PULSATILLA*, and *ANEMONE-HEPATICA*.

Class and order, *Polyandria Polyginia*.

Characters] *CALIX* none. *COROLLA*, six or nine petals, disposed in two or three series. *STAMINA*, numerous capillary short filaments, and double antheræ. *PISTILLUM*, numerous germina collected into a head, pointed styles, and obtuse stigma. *PERICARPIUM* none; the seeds, which are numerous, rest on the receptacle, and form an obtuse cone.

The above characters is applicable, not only to the species commonly considered as *Anemones*, but also to the *Hepatica* and *Pulsatilla*.

First Division.

In this division we will exhibit only all those species commonly called *Anemones*.

The species are,

¹*ANEMONE Coronaria, Angustifolia.*

Narrow-leaved coronated Garden Anemone.] *Anemone* with the radical leaves divided and subdivided by threes, into many narrow segments, and a leafy involucre.

Varieties.] The varieties, in respect to the colour and variegation of the flowers, are innumerable; but the principal plain colours are, red, blue, crimson, purple, ash-colour; and the variegations are, red and white, rose and white, blue and white; red and white and purple, with innumerable intermediate shades; and with single and double flowers, of every colour and variegation.—Proliferous narrow-leaved *Anemone*, one flower growing out of another.

²*ANEMONE Hortensis, Latifolia.*

Broad-leaved Garden Anemone.] *Anemone* with digitate or hand-shaped fingered leaves, having broad segments.

Varieties.] Flowers of many colours and variegations.

³*ANEMONE Nemorosa.*

The Wood Anemone.] *Anemone* with leaves divided by threes, having the segments deeply cut, and one flower on the stalk.

Varieties.] Common Wood *Anemone* with single white flowers.—Double white Wood *Anemone*.—Purple-wood *Anemone*.—Double purple Wood *Anemone*.—Reddish-purple Wood *Anemone*.

⁴*ANEMONE Apennina.*

Apennine Blue Wood Anemone.] *Anemone* with ternate divided leaves, having the segments deeply cut, and numerous spear-shaped petals to the flower.

Varieties.] Common Apennine Wood *Anemone*, with single blue flowers.—Double blue Apennine Wood *Anemone*.—Violet-coloured Apennine Wood *Anemone*.—Double violet-coloured Apennine Wood *Anemone*.

All these species and respective varieties are hardy herbaceous perennials, that will prosper in any common soil of a garden, either in beds separately, or in the borders among other plants of the flowery tribe.

They are perennial in root, but annual in leaf and stalk, which rises in spring, and perishes to the ground when they have flowered and perfected seeds.

The roots are tuberous, knobbed, solid, fleshy, and firm; the leaves rise on footstalks directly from the root, which, in all the sorts, are simple, but are cut into many narrow parts, the divisions being generally by threes; and between the leaves rises the flower-stalk, from five or six inches to one foot in height, surmounted each by one flower, which stands naked without any cup, which, in the single kinds, have generally from six to twelve petals, but in the double sorts the petals are of an indeterminate number, which are often so numerous and full, as to exclude the parts of fructification; but the single and half-double kinds afford plenty of seed annually.

General Description of the Garden kinds.

The two first species, *Anemone Coronaria*, and *Anemone Hortensis*, are the Eastern or Garden *Anemones*, and the parent plants of all those numerous beautiful different coloured single and double varieties that adorn our gardens in spring, and beginning of summer; they are originally natives of the Levant, and other parts of the East; but grow freely with us in the full ground, with little trouble, in beds or borders, and furnish an annual succession of their beautiful flowers six weeks or two months, and perfect abundance of seed annually, and their roots multiply exceedingly.

Their roots, as before hinted, are tuberous, knobbed, irregular, and formed into unequal knobby heads.

The leaves are simple, large, and compound, which, in the first sort, *Anemone Coronaria*, and all its varieties, are deeply divided

vided into many segments, and these again subdivided into numerous narrow divisions; so, for distinction, this species is called Narrow-leaved Anemone. The second sort, *Anemone Hortensis*, and varieties, has also large, simple, decompound leaves, which are digitate or fingered, but the divisions are not so deep, and the fingers or segments being broader than those of the former, it is called Broad-leaved Anemone.

The flower-stalk of both species, and respective varieties, rise between the leaves directly from the roots, frequently two, three, or more, from the same root, and obtain from about eight or nine to ten or twelve inches in height, and a little above its middle grows a leafy appendage, called the involucre, and at top stands one large conspicuous flower, which, in some varieties, is as large as a double rose. In their single state the flowers have only six or nine petals, but in the double kinds they are innumerable: six large petals compose the outward part; in the midst stand numbers of smaller ones, in a great many circular series, filling up the body of the flower in a globular tuft, which, by florists, is called the thrum.

In the single and half-double kinds rise a vast cluster of thread-like stamina, and in the centre of these are the rudiments of the seed, formed in a small roundish head.

But in the full double flowers, all those parts of fructification are often entirely obliterated by the multiplicity of the petals, so that the seeds are to be expected principally from the single and semi-double flowers.

The common single kinds, i. e. with six or nine petals, with the cluster of filaments in the middle, are commonly called Poppy Anemones, from their similarity to a single poppy.

General Description of the Wood Anemones.

The third and fourth species, *Anemone Nemorosa*, and *Anemone Apennina*, grow wild in woods in this country, particularly the former, which is found plentifully in many parts of the kingdom, in their single state; but the double sorts of them have been obtained by culture in gardens from the seeds of the single kinds.

The roots of both these and varieties, are fleshy, oblong, and irregular; run under the surface, and send forth many fibres.

The leaves rise from the root on long foot-stalks; they are pretty broad, and divided into three principal parts, and these again deeply cut on the edges.

The flower-stalk rises from six to eight or nine inches high, having a leafy involucre, and each stalk crowned by one pretty large flower, which, in its single state, have generally six pretty broad petals, in two series, with a cluster of stamina, and a head of rudiments of seeds in the centre; but the double flowers have innumerable small loose petals, forming a globular head, and are very pretty.

Use in Gardens of all the Sorts.

The two first species, and their numerous train of varieties, are very pretty ornaments for the flower-garden, and the double kinds have superior beauty; the varieties in general are curious furniture for embellishing the fronts of the principal compartments of the pleasure ground, as they will prosper in the common open borders, &c. in which they have a fine effect, when properly disposed in assemblage with plants of similar growth and times of flowering, for they blow freely in any common light earth, and nothing injures them but overabundant moisture of soil; and sometimes late frosts in April and May deface the thrum that compose the middle of the flower, but this is seldom.

However, as the capital sorts are often procured at a great price, and some are of singular beauty, it is eligible to plant the best of them separate in narrow beds, in order, that when the plants begin to shew bloom, they may be arched over to be covered with garden mats, when cutting winds and frosts prevail.

But I should advise to plant many of the common kinds in the open borders, towards the front, in small clusters, of three, four, or five in each; in which order the flowers will be very showy, and produce a fine variety for six weeks or two months.

The principal season of flowering of all the double varieties is April and May, but by planting the roots at different times in autumn and spring, the bloom may be continued from March until the middle of June.

The broad-leaved kinds are generally the hardiest blowers, and if some are planted late in March, in a somewhat shady border, they will exhibit a bloom in July.

All the choice double kinds should be taken up annually when the flower is past, in order to separate the increased parts or offsets which arise from the sides of the main roots, and which, if taken up just after the flower fades, may be retained out of ground several

several months, and planted according to the time you design they shall blow.

The Single or Poppy Anemone comes very early into bloom, often in January and February, and its flower, though composed but of six petals, is large and showey, and is worthy of a place in the common borders, which, if disposed four or five together in patches, alternately with bunches of snow-drops, crocuses, winter aconites, hepaticas, and Christmas roses, they will exhibit a fine variety at an early season, and the roots may be permitted to remain two or three years unremoved.

The Wood Anemones are fine furniture for the borders of wood-walks, the fronts of shrubbery clumps, and for wilderness works, and in short, for any other compartments where a variety of early bloom is required, for they will succeed any where.

Method of Planting the Garden Kinds.

The roots of all the varieties of the two species of Eastern or Garden Anemone, are sold by the nurserymen, and at most of the seed-shops. The fine double varieties are generally imported from Holland, which are sold by the hundred, &c. The common kinds, both double and single, by the pound weight.

The Dutch sorts are per hundred from eight or ten shillings to so many guineas, which however is more than they are worth.

The common double English kinds are sold per lb. from five to ten or twelve, and the single or Poppy Anemonies from three to five shillings.

The season for planting all the above varieties, is according to the time it is designed they shall flower.

The best time to plant the principal sorts for the general bloom is October, or early in November, and the plants will come into flower in April and beginning of May; but if some are planted in the middle of September, and a second parcel towards the middle or latter end of October, both plantations will afford a succession of bloom from the beginning of April until the middle of May; and if a third plantation is made in February or beginning of March, they will come into flower about the middle of May, and continue until the middle of June, whereby the bloom may be continued near three months.

In respect to the above times of planting these roots, observe, that those planted early in autumn come up in leaf before Christmas, and they always produce the largest flowers,

and continue longest in beauty; the roots too will be better nourished, and afford a larger encrease than those planted in spring.

It is however necessary always to retain some out of ground till spring, for the sake of a succession of bloom.

The situation proper for the Anemone should be free from copious moisture, and the exposure should be open to the south sun and free air, and unincumbered by the shade of trees, which should be particularly observed for the blow of the capital kinds.

In regard to soil, the Anemone will prosper and flower in tolerable perfection in any common moderately light earth of a garden, only observing to avoid planting them in over-moist and stiff soils, which would rot the roots in winter; and if any augmentation is necessary to raise or form the beds or borders for their reception, no more is needful than common light mould from the quarters of the kitchen garden, or any other well-wrought garden earth, working the whole one good spade deep.

Professed florists, however, in order to blow the capital sorts in their ultimate state of beauty, often prepare composts of different ingredients wherewith to form beds for the reception of the roots.

The best is that of fresh earth from a pasture, neats dung, and sea-sand. Take maiden loamy earth from the surface of a common or other pasture field, the top-spit turf and all; to every load of this add one of neats dung, and half a one of sea or drift-sand; blend the whole together, and form it in a ridge, in which let it remain a year at least, turning it over every two or three months; (see COMPOSTS.) But in default of pasture earth, a good compost may be formed of common light garden mould, and rotted neats dung, adding to every load of the former half a one of the latter, and about a quarter of that of drift or sea-sand; and of either of which composts the bed is to be formed, about twelve or fifteen inches in depth, and three and a half broad.

The mode of planting is to be observed according to the following rules.

If it is designed to plant any of the common double and single kinds in the borders, in assemblage with other plants, I should advise to plant them in patches, that is, to plant three, four, or five roots together, in a patch of five or six inches breadth, putting them two or three inches deep; and those patches

patches may be five, ten, or fifteen feet distance, some near the edge, others more towards the middle; in which order they will make a pretty appearance.

But when it is designed to plant them, in the florist's way, in beds by themselves, they must be planted in continued ranges, lengthways.

The beds for this purpose are to be marked out three feet and half broad, the length at pleasure, with alleys eighteen inches wide between bed and bed. The beds must be worked or prepared one full spade, or fifteen or eighteen inches deep; break the earth small, but do not sift it, observing, that to prevent lodgment of wet, and to give the beds a good appearance, as well as to shew the flowers to the best advantage, it is eligible to elevate them three inches above the common level or general surface; but if there is danger of moisture standing in winter, double or treble that is proper height, working the whole a little rounding, and rake the surface smooth; then put in the roots.

In each bed plant six rows lengthways, the roots at six inches distance in each row, and two or three inches deep; and when one bed is planted, run over it lightly with the rake, to reform all inequalities, and make the surface smooth.

The roots being planted, those of the autumn plantation will come up in leaf in November, but as the plants are hardy, nothing is needful to be done till the bloom begins to appear; and then, if you think proper, to bestow a little care upon the capital sorts, by arching the bed with hoops, in order to cover the bloom with mats occasionally, to protect it from cutting black frosts, which often prevail in April.

To produce a very early bloom of any kind of Anemone, plant some roots in pots in October, and towards Christmas place them either in a hot-house, or upon a common hot-bed, under frames and glasses.

Their Propagation.

All the varieties are propagated by off-sets from the root, and new varieties are obtained from seed.

But first of propagating them by parting the off-sets.

By off-sets, all the kinds encrease exceedingly every year; so the roots of all the capital kinds, at least, should be taken up annually at the decay of the leaf, and the root may be divided or broken into as many pieces

or knobs as are furnished with an eye or bud, and every such part will readily grow, and produce a flower exactly like that of the parent root the spring following; observing however, that if they are divided very small, they flower very weak the first year; therefore, if you would have strong flowers from the main root, only break off those small ones that are slightly affixed thereto; but they should not be thus divided until autumn, or near the time for planting them again.

The time for taking up the roots is in May and June, when the leaf and stalk are withered, for then the roots cease to grow for a month or six weeks; but if they are permitted to stand to put forth fresh fibres again, they should not be removed that season.

They should be taken up in dry weather, and spread in an airy place out of the sun, about a week, then cleared from earth, and put up in bags or boxes till the planting season arrive.

The above work should always be performed annually to the capital kinds, both for the sake of increase, and to fresh dig and prepare the beds.

By propagation by seed all the beautiful varieties were, and continue annually to be obtained.

The process is not very tedious, for the plants will flower the second or third year.

The seed may be had at the shops; but if you save it yourself, it should be from the best single or semi-double flowers; the full doubles afford none. The time to sow it is March, either in boxes, large pots, or wide earthen pans, of perfectly light compost, or in a bed of such earth; sow it moderately thick, and cover it near a quarter of an inch deep with sifted mould: from this time occasional shade from the scorching sun, and moderate waterings in dry weather is necessary, and in six weeks the plants will appear, keeping them clear from weeds; and when the leaves decay, sift a quarter of an inch of earth over the bed, which is all that is necessary till the second summer, when they are to be taken up at the decay of the leaf, and managed as the old roots in the manner already directed, and next spring they will flower and discover many new beauties, and among them many that are very ordinary, which will do for the common borders.

The propagation of the Wood Anemone is by dividing the roots any time after the decay of the leaves in June until October, though the sooner after the fall of the leaf the better.

At which time the common sorts may be transplanted from the woods.

The other species of less note are,

¹ANEMONE *Virginiana*.

Virginian Wood Anemone.] Anemone with a branching stalk, producing long alternate flower-stalks, small whitish flowers, and cylindrical spikes of hairy seeds.

²ANEMONE *Dichotoma*.

Forked-stalked Canada Anemone.] Anemone with a forked stalk, trifid cut leaves, sitting close, growing opposite, and embrace the stalk.

The first grows a foot high, the other almost double that height; the flowers are white, small, and of no great beauty. They may be raised from seed, or by dividing the roots.

Second Division of Anemone.

ANEMONE-PULSATILLA, the *Pulsatilla* or Pasque-Flower.

Class, order, and characters, the same as the Anemone.

The *Pulsatilla* has been always considered as a distinct genus, till the Linnæan botany justly declared all the sorts species of the Anemone.

The plants are herbaceous, hardy perennials, of the flowery tribe, that produce annual stalks ten or twelve inches high, each surmounted by one large flower, bearing great resemblance to those of the Anemone kind, which make a good appearance in the common borders.

The species are,

¹ANEMONE-PULSATILLA *Vulgaris*.

Common large Pulsatilla or Pasque-Flower.] Anemone-Pulsatilla with divided and sub-divided pinnated leaves, having a leafy involucre, nodding flower, and erect petals.

Varieties of this are,] Common Pulsatilla with single blue flowers — with double blue flowers — with single and double white flowers — with single and double red flowers — with violet-coloured flowers — and with flowers having fringed petals.

²ANEMONE-PULSATILLA *Patens*.

Spreading-flowered Siberian Pulsatilla.] Anemone-Pulsatilla with digitate, many-pointed, downy leaves, and upright pale yellow flower with spreading petals, and deep yellow stamina, and with the involucre at a distance from the flower.

³ANEMONE-PULSATILLA *Vernalis*.

Early Smallage-leaved Alpine Pulsatilla.] Anemone-Pulsatilla with simply pinnated leaves, and erect bright yellow flowers.

The plants are perennial in root, but an-

nual in leaf and stalk, which come up in spring, and perish in June or July, when they have flowered and perfected seeds.

The roots are long, thick, fleshy, and of downright growth.

The leaves rise immediately from the root, on foot-stalks, and are decomposed into many very narrow segments.

The flower-stalk rises annually between the leaves, eight, ten, or twelve inches in height, often several from the same root; near the top of each is the leafy many-pointed involucre, serving as a kind of flower-cup, and at top stands one large bell-shaped flower, in magnitude equal to a large single Anemone, is composed of six petals, in two series, with a cluster of stamina in the middle; but in the double flowers the petals are numerous.

They flower in March and April, and the seeds ripen early in autumn.

The Common Pulsatilla grows wild on hills, heaths, and dry pastures in Britain, and other parts of Europe, and the others are natives of the Siberian and Alpine mountains, but they have been long inhabitants of many curious gardens.

The plants are good furniture for the common borders, particularly the first species and respective varieties, and they prosper any where.

The propagation of all the three species is effected by seed, and by dividing the roots. The seed ripens in July, and may be sown soon after, or early in spring, in a bed of light earth.

The propagation by roots is this: take up some of the large roots in July, when their leaves decay, or even any time till October, and such of them that are grown into heads, may be divided into as many parts as have a bud or head at top, which plant, and they will each flower the following spring.

The proper time of year to remove those roots, is any time from the decay of the leaf until Michaelmas.

The roots do not bear to be kept long out of ground.

Third and last Division of Anemone.

ANEMONE-HEPATICA, the Hepatica, or Noble Liverwort.

Class, order, and characters, the same as the Anemone. See ANEMONE.

As the Hepatica, in point of general habit, having been always considered as very different from the Anemone, we, for the greater facility of distinction, treat of it in a separate division, observing however that the whole flower,

flower, though considerably smaller, possesses all the characters of the Anemone; although it was long considered as a distinct genus, principally from the tresfoliate appendage situated near the flower, being mistaken for a calix or cup; but Linnæus considers that only as a three-leaved involucre, common to all the Anemone kind, for there is no calix. See the *Characters*.

There is but one species of Hepatica, of which are many varieties, all very low, herbaceous, flowery perennials, that adorn our gardens in early spring, each with a large tuft of numerous flowers.

The species is,

ANEMONE-HEPATICA, *Hepatica*.

The Hepatica.] Anemone with leaves composed of three roundish undivided lobes, and the involucre situated near the flower.

Varieties of this are,] Hepatica with single and double blue flowers — with single and double red flowers — with single and double red and white flowers — with violet-coloured flowers — with single and double white flowers — and Hepatica with striped leaves.

These plants form themselves into low roundish bunches; the whole, including leaves, flower-stalks, and flowers, never exceed five or six inches in height, which are annual, but the root is of many years duration.

The root is thick, formed into heads, and hath numerous matted fibres.

The flowers appear before the new leaves, but those rise immediately after, the whole rising directly from the root; the flower-stalks are slender, four or five inches high, and rise in great numbers, each supporting one small flower, which, in its single state, hath six petals; but these are numerous in the double flowers, and in all the varieties, they standing in vast clusters make a beautiful appearance in February, March, and April, succeeded in the single kinds by plenty of seed in summer.

All the varieties are choice furniture to adorn the fronts of borders, and other compartments contiguous to the habitation.

The double kinds have the greatest merit, the flowers being larger, and continue longer in bloom, and should occupy the most conspicuous places; but as these can only be increased by dividing the roots, which being remarkably slow of growth, are not so easily acquired as the single kinds, which may be raised plentifully from seed.

The propagation of the single kinds is effected both by seed and parting the roots, but the double sorts only by the latter method.

Observe however, that from seed of single flowers double ones are often obtained.

The seed may be sown in August, September, or March, in a bed or border of light earth, covering it hardly a quarter of an inch deep, and the plants will appear in April and May; give occasional water and weeding, and in August or September prick them upon a border open to the morning sun, where they will flower in spring, and in a year after transplant them where they are to remain.

Those plants being very slow in growth, it will be three years before they form large bunches, so as to produce tolerable clusters of flowers.

The propagation by parting the roots is performed in spring; divide each root into two, three, or more parts, but not too small, because of their reluctant growth; for the merit of the plants is to have them form large bunches, capable of producing fifty or sixty flowers on the same root, which, standing in a compact cluster, make a beautiful appearance.

The seldomer these plants are removed, the stronger and more numerous will be their flowers.

ANETHUM, Dill, Fennel, and Finocchio.

The plants are herbaceous; there are three species, all well known umbelliferous herbs of the kitchen garden.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, the flowers are umbellated, and the umbels are compound, have neither calix nor involucre. COROLLA, the general umbel is uniform, and the florets of the umbel have each five petals. STAMINA, five filaments, and roundish antheræ. PISTILLUM, a germen under each floret, two styles, and obtuse stigmas. PERICARPIMUM none, and the seeds are two succeeding each germen.

The species are,

¹ANETHUM *Graveolens*.

Common Dill, or Rank Anethum.] Anethum with finely divided leaves, and compressed seeds, having borders.

²ANETHUM *Fœniculum*.

Common Fennel or Finckie.] Anethum with decomposed leaves, the lobes finely divided, ending in many points, and oval seed.

Varieties

Varieties of this.] Common light-green-leaved Fennel.—Dark-green-leaved Fennel.—Sweet Fennel, with long slender sparsely leaves, and white sweet seed.

¹*ANETHUM Azoricum.*

Azorian Dwarf Fennel, or Finocchio.] Anethum with a dwarf stalk, swelling, and fleshy near the root, and recurved seed.

These plants are all of hardy growth; the Dill and Finochia are universally annual; the Fennel and its varieties are annual in leaf and stalk, but have perennial roots. The roots are universally spindle-shaped, and grow downright; the leaves are decomposed, with the lobes finely divided into numerous, minute, thread-like segments; and the flower or seed-stems rise from one to five feet high, terminated by the umbels of flowers, succeeded by plenty of seed in August and September.

The Dill rises with a few slender leaves, and a slender erect stem, two or three feet high, the heads or umbels of which, when the seeds are formed, are the parts used in the kitchen for cucumber pickle, &c. and the ripe seeds for medicine.

The *Anethum Fœniculum*, and varieties, hath thick, fleshy, downright roots, which, after the first year, send up a great tuft of large leaves, and strong erect stems, four or five feet high, dividing into many branches. The leaves are the parts used in the kitchen for mackerel, pickled-salmon, garnish to dishes, &c. therefore, the stems of a few plants should be cut down as they advance in summer, to procure a supply of young leaves from the bottom; but for medical purposes, the root, leaves, and seed are used.

The *Finocchio* is a fallad herb. The plant hath a short robust stalk, the bottom of which swells like a large flat turnip, and this being rendered white and tender by blanching, is the part used, which is eaten raw, being sliced and relished with vinegar, oil, pepper, &c.

Propagation, Culture, &c.

They are all propagated by seeds, which, of the Dill and Finocchio, must be sown annually, because the plants endure but one year.

The Dill and Fennel may be sown either in autumn or spring; the autumn sowing generally rise strongest, and should be sown where they are to remain, especially the Dill; they require no particular soil or exposure; sow the seed broad-cast thinly on the surface, and rake it in, and in May or June the

plants must be thinned by hand or hoe, the Dill to six or eight, and the Fennel to twelve or fifteen inches distance.

As the Fennel is of several years standing, it may, for the sake of regularity, be either sown as above, or in drills a foot asunder.

These two species are remarkable for rising abundantly from the self-sown seeds, often sufficient for private service.

The Fennel may also be increased by slipping the large roots, which frequently divide themselves into heads; but these do not succeed so well as the seedling plants.

The *Finocchio* is sown in the middle of March, or beginning of April, and to continue a succession till winter, repeat the sowings every month until July. Chuse an open spot of rich light ground, and by line and hoe draw shallow drills, two feet distance; scatter the seeds thinly along the bottom, and cover them near a quarter of an inch deep with finely broken mould, and when the plants are an inch or two high, small hoe them to kill weeds, and thin them to three inches, and in two or three weeks after cut them out to treble that distance, that the base of the stem may have room to swell.

When the stalks are considerably swelled at bottom, earth them up on each side, and in two or three weeks that part will be very white and tender.

ANGELICA.

This genus furnishes four herbaceous perennials, of large and vigorous growth, obtaining four or five feet stature, branching strongly, garnished with large pinnated leaves, and surmounted by numerous flowers, collected into considerable umbels.

Class and order, *Pentandria Digynia*.

Characters.] **CALIX**, the flower is umbellate, and the umbel is compound; the general umbel has a five, and the partial umbel an eight-leaved involucre, and the calix of the florets is small and five-parted. **COROLLA**, the umbel is uniform, and each floret has five petals. **STAMINA**, five filaments, and simple antheræ. **PISTILLUM**, a germen under each floret, two reflexed styles, and obtuse stigma. **PERICARPIUM** none, the seeds are two, succeeding each germen.

The species are,

¹*ANGELICA Sativa.*

Cultivated, or Garden Angelica.] Angelica with leaves composed of lobes, unequal in size and number.

²*ANGELICA Sylvestris.*

K

Wild

Wild English Angelica.] Angelica with leaves composed of equal spear-shaped serrated lobes.

³ANGELICA *Lucida*.

Shining Canada Angelica.] Angelica with shining leaves, composed of equal oval lobes, the edges cut and serrated.

⁴ANGELICA *Atropurpea*.

Dark-purple Canada Angelica.] Angelica with blackish-green pinnated leaves, having the extreme pair of lobes joined.

All these plants are perennial in root, but the leaves and stalks are renewed annually in spring.

The roots are branching and fibrous.

They send up robust and strongly branching stalks, four or five feet high, adorned with large pinnated leaves, composed of several large lobes, and the ends of all the stalks and branches are terminated by large compound umbels of flowers, succeeded, in all the species, by abundance of seed in August and September.

The Garden Angelica is in great request for its efficaceous properties in medicine; and of its young tender stalks in May, cut into many pieces, is made an admirable sweet-meat. As a garden plant it is sometimes admitted in large pleasure grounds, to encrease the variety, where it cuts a tolerable figure, with its large branching head, considerable foliage, and vast umbels of flowers.

The *Angelica Sylvestris* grows wild by river sides and moist places, and having little merit, is rarely admitted in gardens, unless merely for observation.

The two Canada species possess little virtue or beauty; but being foreigners, and for the sake of variety, are allowed places in many of our gardens, in large grounds, where many plants of easy culture are required.

All these plants delight in moisture, but they rarely disdain any soil or situation.

Propagation.

All the sorts may be raised with facility from seed, in a bed or border of common earth.

The time of year to sow them is either in autumn, i. e. September or October, or early in spring, observing the autumn sowing generally rise strong and regular in spring following, and those sown in spring sometimes rise straggling, so should be sown considerably thicker.

The method of sowing this seed is by broad-cast on the surface, and rake it in,

When the plants are four or five inches high, transplant them into a bed or border of moist earth, fifteen or eighteen inches distance, and give occasional waterings; and if any are required in the pleasure ground for variety, transplant them from the above bed in spring following.

These plants produce only leaves the first year; the second they shoot up stalks, flower, and perfect seeds.

Observe, that when the first stems of those plants are permitted to perfect seeds, the roots frequently perish in winter, in which case a supply must be raised annually; but if the stems are cut down in June, it encreases the root, and it will survive several years.

ANNONA, *Guanabus*, or Custard-Apple, and Papaw-Tree.

The plants are of the tree and shrub kind; there are seven or eight species, one of which is a hardy deciduous shrub, the others mostly ever-green, and of the stove temperament; all the sorts are adorned with simple leaves, and bear large roundish and oblong fruit.

Class and order, *Polyandria Polygynia*.

Characters.] CALIX, five heart-shaped leaves. COROLLA, six petals, the three outermost the largest. STAMINA, the filaments hardly visible, but numerous antheræ. PISTILLUM, a roundish germen placed under the flower, invisible styles, having many obtuse stigma. PERICARPIUM, a large, oblong, oval fruit, of one cell, containing many oval hard seeds.

The species of most note are,

¹ANNONA *Reticulata*.

Netted-fruited Annona, or Custard-Apple.] Annona with spear-shaped pointed leaves, and large, conical, orange-coloured fruit, having a netted rind.

²ANNONA *Muricata*.

Prickly-fruited Annona, or Sour-Sop.] Annona with oval, spear-shaped, plane, smooth, shining leaves, and large oval, greenish-yellow, prickly, four fruit.

³ANNONA *Squamosa*.

Scaly-fruited Annona, or Sweet-Sop.] Annona with oblong-pointed leaves, and small oval, obtuse, scaly, sweet fruit.

⁴ANNONA *Palustris*.

Marsh Annona, or Water-Apple.] Annona with oblong, obtuse, smooth, odoriferous leaves, and round smooth fruit.

⁵ANNONA *Cherimola*.

Cherimola Broad-leaved Annona.] Annona with broad, smooth, shining leaves, and oblong,

oblong, scaly, purple fruit, having a soft sweet pulp.

⁶*ANNONA Triloba.*

Three-fruited Annona, or Papaw-Tree.] *Annona* with large spear-shaped leaves, and inverted pear-shaped fruit, growing by threes on each foot-stalk.

These trees are natives of America, the first five species that of the warmest parts; they are ever-green, and require the constant aid of a stove in this country. But the sixth sort is a hardy deciduous shrub, that prospers here in the full air.

In America, the first five species obtain twenty or thirty feet stature, garnished with beautiful large leaves, which are universally simple, and stand alternate; and flowers proceeding singly from the sides of the branches, succeeded by large fruit, full of a soft pulpy substance, in some very sweet and palatable, that of the *Annona Reticulata* being of the texture of a custard, whence it, in America, derived the appellation of Custard-Apple.

These five species however never produce fruit in Europe, and rarely flower, so are retained here in stoves by the curious for variety, and the beauty of their ever-green leaves.

The *Annona Triloba* or Hardy Papaw, is of North America; it rises twelve or fifteen feet high, the leaves very large and alternate, and the flowers are of a chocolate colour, which sometimes appear here in May, but never any fruit.

Propagation, Culture, &c.

All the sorts are propagated by seed.

The seeds are imported from America by many of the London seedsmen, &c. they are to be sown as soon as they arrive; those of the tender kind in pots of light rich earth, and plunged in a bark-bed under glasses; and when the plants are three inches high, prick them in separate pots, give water, and plunge them in the bark-bed in the stove, where they must be always retained and treated as other woody plants of that department.

The seeds of the hardy *Annona* may either be sown in a bed of common light earth, or in pots or boxes, which latter, at the approach of winter, may be moved into the greenhouse, or shelter of a frame, for the plants are impatient of severe frost whilst young, so the seedlings should be planted in pots to have occasional shelter the first two or three winters, then turned out into the full ground.

If the plants do not rise the first year, plunge the pots upon a hot-bed in spring.

ANTHEMIS, Chamomile.

This genus furnishes upwards of twenty species of herbaceous plants, consisting of annuals and perennials; of which not more than five or six merit notice, either for use or ornament.

Class and order, *Syngenesia Polygamia Superflua.*

Characters.] *CALIX* is hemispherical and scaly. *COROLLA*, a compound radiated flower, the disk or middle composed of funnel-shaped hermaphrodites, and the radius of flat female florets. *STAMINA*, five filaments in the hermaphrodite flowers. *PISTILLUM*, a germen, simple style, and two reflexed stigmas. *PERICARPIMUM* none, the seeds sit naked on the receptacle.

The species of note are,

¹*ANTHEMIS Nobilis.*

Noble or Common Chamomile.] *Anthemis* with pinnated leaves, composed of numerous minute, acute-pointed, somewhat hairy segments.

Varieties.] Common Chamomile with single white flowers — with double white flowers — with very large double white flowers.

²*ANTHEMIS Maritima.*

Maritime or Sea Chamomile.] *Anthemis* with pinnated, fleshy, indented, dotted, naked leaves, trailing branching stalks, and white flowers.

³*ANTHEMIS Tomentosa.*

Downy Grecian Sea Chamomile.] *Anthemis* with pinnated, plane, obtuse, many-pointed, downy leaves, branching stalks, and white flowers.

⁴*ANTHEMIS Tinctoria.*

Tinctored Ox-eye Anthemis.] *Anthemis* with tall erect stalks, doubly-pinnated sawed leaves, woolly underneath, and large flowers growing in a corymbus.

Varieties.] Common German Ox-eye *Anthemis* with white flowers. — Great Oriental Ox-eye *Anthemis* with sulphur-coloured flowers — with yellow flowers — with scarlet flowers — with pale red flowers — and with large white flowers.

⁵*ANTHEMIS Pyrethrum.*

Pyrethrum or Pellitory of Spain.] *Anthemis* with trailing branches, pinnated, finely divided leaves, and each branch terminated by one large flower.

All these are hardy perennials, closely adorned with numerous pinnated leaves, finely

finely divided into a multitude of minute parts, and compound radiated flowers, but the radius is not distinct in the double kinds.

The *Anthemis Nobilis* is the Odoriferous or Common Chamomile, well known for the medical virtues of its flowers, which are equally efficacious in all its varieties, and the plants merit culture in every garden. The two double kinds merit culture also as flowering plants; the common double sort is well known; its flowers, though small, are perfectly full and pretty; but the large double kind is almost three times as big, and are very beautiful.

They are low trailing plants, spreading themselves upon the surface of the earth; their branches emitting roots as they advance, and multiply exceedingly, and produce numerous flowers in June, July, and August, or even till October.

The *Anthemis Maritima* and Downy Anthemis are low, bushy plants, and produce numerous flowers from July until November, and may be admitted to form variety in the compartments of pleasure grounds.

The *Anthemis Tinctoria* and varieties are spreading plants, and send up branching stems a yard high, ornamented with corymbuses of flowers from June until November, and make a good appearance in the shrubbery compartments.

The *Pellitory of Spain* hath a carrot shaped root, and branches spreading a foot each way on the ground, producing large solitary flowers in June and July.

The root of this species afford relief in the tooth-ach.

Propagation, &c.

The Common Chamomile and varieties are propagated by parting the roots, and by slips and cuttings of their trailing branches.

The best season for this is March and April, although it may be done in any of the summer months. Those intended for medical use must be planted in a bed or border, in little tufts, nine inches or a foot asunder; give some water, and they will soon spread and produce plenty of flowers the same year.

If the double sorts are designed as flowering plants, set them in little bunches in different parts of the borders.

The other four species are easily raised from seed, in a bed of common earth, in March and April; likewise by slips and cuttings of their branches, in a shady border, any time in summer; afterwards transplant

them into the fronts of shrubberies, where they will endure many years, and flower annually.

To this genus belong also all the May-weeds of the fields, having leaves somewhat like Chamomile, and white radiated flowers, with yellow middles.

ANTHERÆ, the Apex, Summit, or Top of the Stamina, or Stamen of Flowers, and is elevated by means of the filaments. See STAMEN and FILAMENTUM.

This part of the flower, i. e. Antheræ, is of the utmost utility in the generation of plants; for, according to the sexual system, it is the principal part of the male organs, and contains the fecundating *pollen*, or fine and coloured dust, absolutely necessary for the impregnation of the female parts of the fructification of flowers, to render them prolific or fruitful, and to fertilize the seeds, which otherwise would prove abortive.

The sexual system being founded on the supposed impregnation of the seeds by the male dust or powder contained in the Antheræ, the importance of that part of the flower is considerably augmented. See SEXUS.

The Antheræ produces, and, when ripe, discharges a powder called *pollen*, which falling upon the stigma, or female organ, is absorbed by a tough and viscid humour, with which the surface of that part is covered, and passing from thence through the style, impregnates the germen or ovarium below (see STYLUS and GERMEN;) and after this operation of nature, the fruit or seed immediately take their growth, which, in some plants, is very quick and conspicuous, particularly exemplified in the cucumber; as I have often observed, that from the time of impregnating the female flower with the Antheræ of the male blossom, which I always practise to the early crops, that the fruit, from the size of a large barley-corn, have obtained four, five, or six inches in length in a fortnight; the cucumber and melons being androgynous plants, i. e. produce male and female flowers apart on the same root, that the office of fecundating the fruit naturally, is supposed to be accomplished in the general summer crops in the full ground, by the winds or insects, such as bees, flies, &c. conveying the male dust, and shedding it over the stigma or pointal of the female flower; but in the early crops in hot-beds, under frame and glasses, where we may suppose the winds and insects have

have no access, recourse is had to art, to perform the office of impregnation, or, as the gardener's call it, setting the fruit, which is effected by carrying the stamina of the male, commonly, though improperly, called the false blossom, to the female, and touching the stigma therewith, so as to leave part of the dust of the Antheræ, and in a day or two after the fruit will visibly swell. See the *Culture of Cucumbers*.

The above operation of impregnating cucumbers with the Antheræ of the male blossom is so essential, that I advise every one to practise it with the utmost attention in the early crops, as from many years experience I can affirm it to be of the greatest importance, for I always made sure of my first fruit, and even every one that shewed and blossomed; whereas, when left entirely to nature, in the early crops, seldom one in ten or twenty stands; but when the season arrives that the plants can be exposed to the free air, that function is always sufficiently effected, as above observed, by the winds, insects, &c. or by some other unknown operation of nature. *Vide CUCUMIS, IMPREGNATION OF FRUIT, SEXUS, &c.*

The most natural structure of the Antheræ, which obtain in the greater number of plants, is, in point of situation, placed on the top of the filament; in point of number, a single Antheræ to each filament, though some plants have two, others three, four, and five Antheræ.

The connection of the Antheræ with the filament is either *Erectæ*, erect, or strait, and fastened by either end to the top of the filament; *Incumbentes*, incumbent, or lie sideways upon the filament; or *Versatiles*, veering about like a vane.

The figure and resemblance of the Antheræ is various, some are *Linearis*, linear, or slender, like a thread; *Subulata*, or awl-shaped; *Hastata*, spear, or javelin-shaped; *Bicornes*, two-horned; *Bifida*, parted half-way; *Biloba*, divided into two; *Sagittata*, arrow-shaped; *Cordata*, heart-shaped; *Reniformis*, kidney-shaped; *Ovata*, egg-shaped; *Globosa* or *Rotunda*, globular or round; *Trigona*, three cornered; *Tetragona*, four cornered; *Lunata*, crescent, or moon-shaped; *Acuta*, sharp, terminated in an acute angle; *Acuminata*, tapering to a point; *Obtusa*, obtuse, or blunt; *Distincta*, distinct, or unconnected with each other; *Connivens*, approaching each other; *Incurva*, bowed, or crooked;

Villosa, hairy and woolly; *Hirsuta*, rough and hairy; *Membranacea*, membranaceous or hard, like parchment; *Pellucida*, shining or transparent.

ANTHERICUM, Spider-Wort.

The plants are herbaceous, mostly perennial, and of the flowery kind, obtaining in stature, in different species, from three inches to three feet, adorned with hexapetalous liliaceous flowers, disposed in spikes.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX none. COROLLA, six obtuse spreading petals. STAMINA, six filaments, and incumbent furrowed antheræ. PISTILLUM, a trigonous germen, simple style, and trigonous stigma. PERICARPIUM, a smooth three-furrowed capsule, of three cells, containing many seeds.

There are twelve species, those that claim attention are,

¹ANTHERICUM *Revolutum*.

Revolute-flowered Anthericum.] Anthericum with flat rough leaves, erect branching stalks, two feet high, each branch terminated by a loose spike of white flowers, having the petals rolled back.

²ANTHERICUM *Ramosum*.

Ramose-stalked plane-flowered Anthericum.] Anthericum with flat leaves, erect very branching stalks, two feet high, each branch terminated by a loose spike of white flowers, with strait petals.

³ANTHERICUM *Liliago*.

Liliago or Single-stalked Anthericum.] Anthericum with plane flat leaves, an erect unbranched stalk, a foot and half high, supporting one loose spike of white flowers.

⁴ANTHERICUM *Liliumstrum*.

Liliumstrum, or St. Bruno's Lily.] Anthericum with plane, flat, erect leaves, erect undivided stalk, fifteen or eighteen inches high, and large bell-shaped, lily-like, white, odoriferous flowers at top of the stalk, hanging on one side, which are very pretty, but rarely endure five or six days.

⁵ANTHERICUM *Frutescens*.

Shrubby-stalked Anthericum, or Onion-leaved Aloe.] Anthericum with several shrubby-branches from the root, each supporting a head of taper, onion-like, fleshy leaves, and loose spikes of yellow flowers.

⁶ANTHERICUM *Aleooides*.

Aloe-leaved Anthericum.] Anthericum with broad, flat, awl-shaped, fleshy leaves, rising from the root, spreading on the ground, and loose

loose spikes of yellow flowers rising among the leaves.

¹ANTHERICUM *Asphodeloides*.

Mock-Asphodel Anthericum] Anthericum with long, narrow, awl shaped, half-tapered, fleshy leaves, gathered close together, and loose spikes of yellow flowers rising among the leaves.

The four first species are hardy perennials, the roots are mostly fleshy tubers, especially the three first; the leaves and stems rise from the root annually in spring, flower in June and July, and ripen seed in autumn.

All these are proper furniture for the principal compartments of the pleasure ground.

The *Anthericum Frutescens*, *Alocoides*, and *Asphodeloides*, are green-house plants, so must be retained always in pots; they are succulent, and retain their leaves, and flower at different seasons, and often perfect seeds.

The flowers of all the sorts are liliaceous, and composed each of six equal petals. See its *Characters*.

Propagation.

The *Anthericum Revolutum*, *Ramosum*, and *Liliago*, are propagated by seed, in a bed or border of light earth, in September or October, and the plants will rise plentifully in spring; which, in autumn, when the leaves decay, transplant into a fresh bed, nine inches distance, to remain a year; then remove them into the borders, &c.

The roots sometimes afford off-sets, which may be separated for encrease in autumn.

The St. Bruno's Lily multiply freely by off-sets of the roots, which may be divided in autumn, planting the small slips in a nursery bed for a year, and the larger ones at once where they are to remain.

The three green-house kinds may be raised from seed, but they encrease exceedingly by off-sets or suckers, which may be taken off in summer, and planted in pots of light sandy earth, and in winter must have the shelter of a green-house or garden-frame, and managed as other succulent plants.

ANTHOLYZA, sometimes called Æthiopian Corn Flag.

The plants are herbaceous perennials, of the bulbous-rooted tribe, producing stalks from one to two feet high, ornamented with clusters of large monopetalous flowers, of singular structure and beauty.

Class and order, *Triandria Monogynia*.

Characters.] CALIX is a spathæ. COROLLA, one irregular ringent petal, tubular

below, widening gradually to a large compressed ringent mouth, the upper lip very long and erect, with two short wings at the base; the under lip short and trifid. STAMINA, three long filaments, and pointed antheræ. PISTILLUM, a germen below the corolla, slender style, and trifid stigma. PERICARPIUM, a trigonous capsule of three cells, and many seeds.

The species are,

¹ANTHOLYZA *Ringens*.

Ringent or Gaping scarlet Antholyza.] Antholyza with narrow, rough, furrowed leaves, a foot long; round hairy flower-stalk, two feet high, ornamented upward with several red flowers, having compressed jaws and gaping lips.

²ANTHOLYZA *Spicata*.

Half-spiked White Antholyza.] Antholyza with long, narrow, deeply-furrowed leaves; a flower-stem eighteen inches high, and white flowers, ranged all on one side, standing erect.

³ANTHOLYZA *Æthiopica*.

Æthiopian Crimson Antholyza.] Antholyza with long, narrow, deep-green leaves; a round flower-stem a foot high, the top ornamented with large, incurved, crimson flowers.

⁴ANTHOLYZA *Cunonia*.

Cunonia, or Large Spathæed Scarlet Antholyza.] Antholyza with narrow, sword-shaped, pointed leaves, nine inches long, rising in autumn, and the flower-stem in spring, eighteen inches high, ornamented upward with large scarlet flowers, have a large spathæ, and want the under lip.

These are exotics of Africa, and require the protection of a stove or good green-house in winter, so must be always retained in pots.

They have bulbous perennial roots, but the leaves and stems are annual, rise in spring, and flower in May and June; the flowers are elegant, and universally monopetalous, long, hollow, divided into six irregular segments, one of which is considerably extended, the whole extremely singular and beautiful, and are succeeded by plenty of ripe seeds in autumn.

Their propagation is by off-sets from the roots, which may be taken up and separated when the leaves decay.

They may also be propagated with facility by seeds sown in autumn, in pots of light earth, which place in the green-house in winter, and the plants will appear in spring, and in two years transplant them into separate pots.

ANTHOS-

ANTHOSPERMUM, Amber-Tree.

This is a beautiful, evergreen, odoriferous shrub, of the green-house.

Class and order, *Polygamia Dioecia*, i. e. hermaphrodite, and male and female flowers upon one plant, and only males or females upon another.

There are two species.

¹**ANTHOSPERMUM Æthiopicum.**

Æthiopian Smooth Amber-Tree.] Anthospermum with an erect very branching stem, and numerous, very small, smooth leaves.

²**ANTHOSPERMUM Giliare.**

Ciliated Cape Anthospermum.] Anthospermum with procumbent or trailing stalks, eight or ten inches long, and narrow spear-shaped leaves, having hairy borders.

The *Anthospermum Æthiopicum* is the sort commonly known here; it is a low shrub, the stem erect, and divides into numerous slender branches, closely covered with very small, ever-green, fragrant leaves, and flowers from the sides of the branches, which being devoid of petals, have no beauty; so that the merit of the plant is its being a pretty ever-green, of delightful fragrance.

Both these species require the shield of a green-house in winter, so must be cultivated in pots.

The propagation of both sorts is effected by cuttings and layers of their young branches; the cuttings may be planted in May, June, or July, either in pots, or in a bed or border, giving occasional shade, and they will be fit to transplant into separate pots in two or three months.

ANTHYLLIS, Barba Jovis, or Jupiter's Beard; also Silver Bush.

This genus furnishes ever-green shrubs and herbaceous plants; the former chiefly merit culture, which are exotics of the green-house, adorned with compound leaves, and papilionaceous, or butterfly-shaped flowers.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX**, monophyllous, swelling, five-parted, and permanent. **COROLLA** is papilionaceous, the standard long, both sides reflexed, the wings and keel short. **STAMINA**, ten filaments, simple antheræ. **PISTILLUM**, an oblong germen, simple style and stigma. **PERICARPIUM**, a roundish pod, having one or two seeds.

The species are,

¹**ANTHYLLIS Barba Jovis.**

Common Barba Jovis, or Jupiter's Beard.] Anthyllis with shrubby stem and branches,

nine or ten feet high, ornamented with winged silvery leaves, composed of many lobes, and bright yellow flowers in bunches at the ends of the branches.

²**ANTHYLLIS Cytisoides.**

Bastard Cytisus, or Ternate-leaved Spanish Barba Jovis.] Anthyllis with shrubby stem and branches, two feet high, leaves composed of three oval hoary lobes, and yellow flowers, by twos or threes from the sides of the branches.

³**ANTHYLLIS Heterophyllis.**

Dwarf Portugal Barba Jovis] Anthyllis with low shrubby stem and branches, spreading near the ground, pinnated silvery leaves, terminated by an odd lobe, and small variegated flowers at the ends of the branches.

⁴**ANTHYLLIS Hermania.**

Cretan Ternate-leaved Barba Jovis.] Anthyllis with shrubby stem and branches, rising five feet high, ternate leaves, and yellow flowers in clusters from the sides of the branches.

⁵**ANTHYLLIS Erinacea.**

Erinacea, or Prickly Anthyllis.] Anthyllis with shrubby and very prickly stem and branches, growing six or eight feet high, oval simple leaves, and purplish flowers.

These are all exotic ever-greens of the green-house, so must be always kept in pots for the convenience of moving them in and out occasionally.

They are natives of Portugal, Spain, Italy, and Greece.

The *Anthyllis Barba Jovis* is a most beautiful ever-green shrub, although it may be said to be white, for the leaves appear of a silvery white colour, hence it is sometimes called Silver Bush.

The *Anthyllis Cytisoides* is also a pretty hoary shrub.

The other three species are at present but rare in this country.

All the sorts flower annually in June and July; the flowers are universally butterfly-shaped, having a standard, two wings, and the keel, which are often succeeded by ripe seeds in autumn.

The propagation of all the species is by seeds, cuttings, and layers.

By seeds, sow them in pots in spring, which plunge in a moderate hot-bed just to bring up the plants, and they must afterwards be planted in separate pots.

By cuttings, plant them in May or June,

in

in a shady border, and they will be well-rooted by autumn.

Layers of the young branches may be performed at any time.

The following are herbaceous species of this genus.

¹*ANTHYLLIS Montana.*

Mountain Herbaceous Anthyllis, or Purple Milk Vetch.] Anthyllis with trailing stalks, winged hairy leaves, having an equal number of lobes, and purple flowers in globular heads at the ends of the branches.

²*ANTHYLLIS Vulnaria.*

Vulnaria, or Scarlet Lady's Finger.] Anthyllis with slender stalks, winged leaves, of two or three pair of lobes, terminated by an odd one, and double heads of scarlet flowers at the ends of the stalks.

They are hardy perennials, and proper furniture for the pleasure ground, and may be raised from seed in autumn or spring, and by parting their roots.

ANTIRRHINUM, Snap-Dragon, or Calve's-Snout; also *Linnaria*, or Toad-Flax, or Frog's-Mouth.

The plants are herbaceous, and of the flowery kind, producing erect stalks from one to three feet high, terminated by long erect spikes of numerous monopetalous grinning flowers.

The Snap-Dragons are often seen growing upon walls and ruins.

Class and order, *Didynamia Angiospermia.*

Characters.] *CALIX* is monophyllous, and deeply five-parted. *COROLLA* is monopetalous and ringent, the tube oblong, swelling, and opening above with a mouth, having two lips, the upper one two-parted and reflexed on each side, the under one trifid and obtuse, and a prominent nectarium at the base of the flower. *STAMINA*, two short and two long filaments. *PISTILLUM*, a roundish germen, simple style, and stigma. *PERICARPIUM*, a roundish capsule, having many seeds.

The four following are of the Snap-Dragon *Antirrhinums*, distinguished from the *Linnaria* by having the nectarium placed within the corolla, which, in the Toad-Flax, is extended at the base like a spur or horn.

¹*ANTIRRHINUM Majus.*

Great Perennial Snap-Dragon.] Antirrhinum with erect stems, two or three feet high; spear-shaped leaves, having foot-stalks, and the stem terminated by a long spike of many large flowers.

Varieties.] Great Perennial Snap-Dragon

with red flowers—with white flowers—white and red flowers—with white mouthed red flowers—with yellow flowers—yellow and red flowers—yellow and white flowers—with purple flowers—purple and white shaded flowers—and Variegated-leaved Great Snap-Dragon with flowers of different colours.

²*ANTIRRHINUM Latifolium.*

Broad-leaved Greatest Perennial Snap-Dragon.] Antirrhinum with erect stems, a yard high; broad spear-shaped smooth leaves, on short foot-stalks, and the stem terminated by a very long spike of many elegant large flowers.

Varieties.] The flowers of many different colours like the former.

³*ANTIRRHINUM Italicum.*

Italian Perennial White Snap-Dragon.] Antirrhinum with stems two feet high, very long, narrow, spear-shaped, hairy leaves, the stems adorned at top with a short robust spike of large white flowers.

⁴*ANTIRRHINUM Siculum.*

Sicilian Annual White Snap-Dragon.] Antirrhinum with stems fifteen inches high, narrow spear-shaped alternate leaves, white flowers with purple bottoms, arising singly on long foot-stalks from the sides of the branches.

The following are the *Linarias*, or Toad-Flax *Antirrhinums*, distinguishable from the Snap-Dragons by the flower being terminated behind by the nectarium, like a spur or horn, on which consideration, Miller ranges it as a distinct genera; but Linnæus places them among the *Antirrhinums*.

⁵*ANTIRRHINUM Linaria, Vulgaris.*

Linaria, or Common Toad-Flax] Antirrhinum with many erect stems, eighteen inches high, adorned below with numerous, very narrow, spear-shaped, grey leaves, in clusters, and each stem terminated by a long spike of many close-fitting flowers.

Varieties.] Common large Toad-Flax with yellow flowers, and golden chaps.—Large White Toad-Flax—Small Yellow Toad-Flax.

⁶*ANTIRRHINUM Purpureum.*

Great Purple Sweet-scented Linaria.] Antirrhinum with many erect, branching, very flowery stems, a yard high, long, narrow, spear-shaped leaves, placed sparsely, all the stems terminated by long loose spikes of many large, purple, sweet-scented flowers.

⁷*ANTIRRHINUM Triflis.*

Dark-mouthed Gibraltar Toad-Flax.] Antirrhinum

rhinum with many declinated succulent stalks, hardly a foot long, very short, narrow, succulent leaves, opposite below, but irregular above, the stems terminated by clusters of close-fitting yellow flowers, striped with purple, dark purple chaps, and awl-shaped nectariums.

¹ANTIRRHINUM *Arvensis*.

Field, or Wild Blue Toad-Flax.] Antirrhinum with many erect, very branchy stems, two feet high, narrow leaves in whorls below, by pairs or singly above, and all the stems and branches terminated by loose spikes of many small blue flowers.

Variety.] Field Toad-Flax with yellow flowers.

²ANTIRRHINUM *Dalmatica*.

Dalmatian Shrubby Yellow Toad-Flax.] Antirrhinum with a strong, erect, woody stem, a yard high, broad, spear-shaped, alternate, close-fitting leaves, and large deep yellow flowers, in loose spikes, at the ends of the branches.

³ANTIRRHINUM *Triphylla*.

Three-leaved Annual Toad-Flax.] Antirrhinum with erect branchy stems, near two feet high, oval smooth leaves by threes, and short spikes of flowers terminate the branches.

Varieties are,] Three-leaved Toad-Flax with yellow flowers—yellow with purple standard and spur—with purple flowers.

All these plants are herbaceous, and all perennials, except the *Antirrhinum Siculum* and *Triphylla*, which are annuals, and are mostly of hardy temperature, and will succeed in any of the common compartments of the pleasure ground; though the *Antirrhinum Tristis* and *Dalmatica* is somewhat impatient of severe frost.

The roots are fibrous, the stems rise several from each root, and the leaves are universally simple, and mostly long and narrow.

The flowers are formed universally of one hollow, grinning petal, resembling the snout and mouth of an animal, hence the names Snap-Dragon, Calve's-Snout, Frog's-Mouth, &c.

Culture of the Snap-Dragon Kinds.

The Snap-Dragon *Antirrhinums* are extremely pretty garden flowers, but more particularly those of the *Antirrhinum Majus* and *Latifolium*, and are of remarkably easy culture, as is obvious by the plants rising spontaneously from the self-sown or scattered seeds, even out of the crevices of walls, buildings, and ruins, so that they are also good furniture for artificial ruins, rock-work, &c. And in gardens, those that grow in dry, sandy, gra-

velly, rubbishy, or any dry hungry soil, are also of several years duration; though in rich land they grow strongest, and the flowers will be more large and elegant; in which soil, however, they are apt to acquire a luxuriance, or sponginess, and rarely abide longer than one or two years; but this is no inconvenience, since they may be raised plentifully by seed and by slips and cuttings.

They flower from June to the end of summer, and ripen plenty of seed in autumn.

The seeds may be sown in March, April, and May; those sown in March will flower the same year in autumn, and the others the year following. Sow them in a bed of light soil, and when the plants are three inches high, transplant them; those you intend shall blow the same year, may be sown in patches where they are to flower, as directed for hardy annuals.

By slips and cuttings is the method to continue the variegated-leaved sort; any of the others will also grow freely by cuttings in a shady border in summer.

The variegated kind is rather impatient of severe frost, and a few plants should be potted to be housed in winter.

Culture of the Toad-Flax Kinds.

Of the Toad-Flax *Antirrhinums*, the Common *Linaria*, *Antirrhinum Purpureum*, *Arvensis*, and *Triphylla*, are proper furniture for the common compartments of large pleasure grounds. The Purple *Linaria* particularly merit a place in every garden. All these sorts flower in June, and continue in succession till the end of summer, and are succeeded by abundance of seed in autumn.

The Common Toad-Flax grows wild by the way sides, that of banks, hedges, and pastures, as also the *Antirrhinum Arvensis*; but by culture in gardens they grow strong, and produce larger flowers.

All the sorts may be raised plentifully from seed, the same as the Snap-Dragons; and the perennial sorts also by parting the roots.

The Dalmatian *Linaria* and *Antirrhinum Tristis* are somewhat tender, and some plants should be potted to be housed in winter, and some may be planted in warm dry borders; they flower in June and July, but rarely afford seeds here.

They are easily increased by slips and cuttings of their branches in summer, or by parting their roots in autumn.

•APETALUS *Flos*, i. e. Apetalous Flowers. By botanists, a flower is said to be Apetalous that wants the corolla, petals, or flower-leaves.

in a shady border, and they will be well-rooted by autumn.

Layers of the young branches may be performed at any time.

The following are herbaceous species of this genus.

¹*ANTHYLLIS Montana.*

Mountain Herbaceous Anthyllis, or Purple Milk Vetch.] Anthyllis with trailing stalks, winged hairy leaves, having an equal number of lobes, and purple flowers in globular heads at the ends of the branches.

²*ANTHYLLIS Vulnaria.*

Vulnaria, or Scarlet Lady's Finger.] Anthyllis with slender stalks, winged leaves, of two or three pair of lobes, terminated by an odd one, and double heads of scarlet flowers at the ends of the stalks.

They are hardy perennials, and proper furniture for the pleasure ground, and may be raised from seed in autumn or spring, and by parting their roots.

ANTIRRHINUM, Snap-Dragon, or Calve's-Snout; also *Linnaria*, or Toad-Flax, or Frog's-Mouth.

The plants are herbaceous, and of the flowery kind, producing erect stalks from one to three feet high, terminated by long erect spikes of numerous monopetalous grinning flowers.

The Snap-Dragons are often seen growing upon walls and ruins.

Class and order, *Didynamia Angiospermia.*

Characters.] *CALIX* is monophyllous, and deeply five-parted. *COROLLA* is monopetalous and ringent, the tube oblong, swelling, and opening above with a mouth, having two lips, the upper one two-parted and reflexed on each side, the under one trifid and obtuse, and a prominent nectarium at the base of the flower. *STAMINA*, two short and two long filaments. *PISTILLUM*, a roundish germen, simple style, and stigma. *PERICARPIUM*, a roundish capsule, having many seeds.

The four following are of the Snap-Dragon *Antirrhinums*, distinguished from the *Linnaria* by having the nectarium placed within the corolla, which, in the Toad-Flax, is extended at the base like a spur or horn.

¹*ANTIRRHINUM Majus.*

Great Perennial Snap-Dragon.] Antirrhinum with erect stems, two or three feet high; spear-shaped leaves, having foot-stalks, and the stem terminated by a long spike of many large flowers.

Varieties.] Great Perennial Snap-Dragon

with red flowers—with white flowers—white and red flowers—with white mouthed red flowers—with yellow flowers—yellow and red flowers—yellow and white flowers—with purple flowers—purple and white shaded flowers—and Variegated-leaved Great Snap-Dragon with flowers of different colours.

²*ANTIRRHINUM Latifolium.*

Broad-leaved Greatest Perennial Snap-Dragon.] Antirrhinum with erect stems, a yard high; broad spear-shaped smooth leaves, on short foot-stalks, and the stem terminated by a very long spike of many elegant large flowers.

Varieties.] The flowers of many different colours like the former.

³*ANTIRRHINUM Italicum.*

Italian Perennial White Snap-Dragon.] Antirrhinum with stems two feet high, very long, narrow, spear-shaped, hairy leaves, the stems adorned at top with a short robust spike of large white flowers.

⁴*ANTIRRHINUM Siculum.*

Sicilian Annual White Snap-Dragon.] Antirrhinum with stems fifteen inches high, narrow spear-shaped alternate leaves, white flowers with purple bottoms, arising singly on long foot-stalks from the sides of the branches.

The following are the *Linarias*, or Toad-Flax *Antirrhinums*, distinguishable from the Snap-Dragons by the flower being terminated behind by the nectarium, like a spur or horn, on which consideration, Miller ranges it as a distinct genera; but Linnæus places them among the *Antirrhinums*.

⁵*ANTIRRHINUM Linaria, Vulgaris.*

Linaria, or Common Toad-Flax] Antirrhinum with many erect stems, eighteen inches high, adorned below with numerous, very narrow, spear-shaped, grey leaves, in clusters, and each stem terminated by a long spike of many close-fitting flowers.

Varieties.] Common large Toad-Flax with yellow flowers, and golden chaps.—Large White Toad-Flax—Small Yellow Toad-Flax.

⁶*ANTIRRHINUM Purpureum.*

Great Purple Sweet-scented Linaria.] Antirrhinum with many erect, branching, very flowery stems, a yard high, long, narrow, spear-shaped leaves, placed sparsely, all the stems terminated by long loose spikes of many large, purple, sweet-scented flowers.

⁷*ANTIRRHINUM Triflis.*

Dark-mouthed Gibraltar Toad-Flax.] Antirrhinum

rhinum with many declinated succulent stalks, hardly a foot long, very short, narrow, succulent leaves, opposite below, but irregular above, the stems terminated by clusters of close-fitting yellow flowers, striped with purple, dark purple chaps, and awl-shaped nectariums.

⁸ANTIRRHINUM *Arvensis*.

Field, or Wild Blue Toad-Flax.] Antirrhinum with many erect, very branchy stems, two feet high, narrow leaves in whorls below, by pairs or singly above, and all the stems and branches terminated by loose spikes of many small blue flowers.

Variety.] Field Toad-Flax with yellow flowers.

⁹ANTIRRHINUM *Dalmatica*.

Dalmatian Shrubby Yellow Toad-Flax.] Antirrhinum with a strong, erect, woody stem, a yard high, broad, spear-shaped, alternate, close-fitting leaves, and large deep yellow flowers, in loose spikes, at the ends of the branches.

¹⁰ANTIRRHINUM *Triphylla*.

Three-leaved Annual Toad-Flax.] Antirrhinum with erect branchy stems, near two feet high, oval smooth leaves by threes, and short spikes of flowers terminate the branches.

Varieties are,] Three-leaved Toad-Flax with yellow flowers—yellow with purple standard and spur—with purple flowers.

All these plants are herbaceous, and all perennials, except the *Antirrhinum Siculum* and *Triphylla*, which are annuals, and are mostly of hardy temperature, and will succeed in any of the common compartments of the pleasure ground; though the *Antirrhinum Trifidum* and *Dalmatica* is somewhat impatient of severe frost.

The roots are fibrous, the stems rise several from each root, and the leaves are universally simple, and mostly long and narrow.

The flowers are formed universally of one hollow, grinning petal, resembling the snout and mouth of an animal, hence the names Snap-Dragon, Calve's-Snout, Frog's-Mouth, &c.

Culture of the Snap-Dragon Kinds.

The Snap-Dragon *Antirrhinums* are extremely pretty garden flowers, but more particularly those of the *Antirrhinum Majus* and *Latifolium*, and are of remarkably easy culture, as is obvious by the plants rising spontaneously from the self-sown or scattered seeds, even out of the crevices of walls, buildings, and ruins, so that they are also good furniture for artificial ruins, rock-work, &c. And in gardens, those that grow in dry, sandy, gra-

velly, rubbishy, or any dry hungry soil, are also of several years duration; though in rich land they grow strongest, and the flowers will be more large and elegant; in which soil, however, they are apt to acquire a luxuriance, or sponginess, and rarely abide longer than one or two years; but this is no inconvenience, since they may be raised plentifully by seed and by slips and cuttings.

They flower from June to the end of summer, and ripen plenty of seed in autumn.

The seeds may be sown in March, April, and May; those sown in March will flower the same year in autumn, and the others the year following. Sow them in a bed of light soil, and when the plants are three inches high, transplant them; those you intend shall blow the same year, may be sown in patches where they are to flower, as directed for hardy annuals.

By slips and cuttings is the method to continue the variegated-leaved sort; any of the others will also grow freely by cuttings in a shady border in summer.

The variegated kind is rather impatient of severe frost, and a few plants should be potted to be housed in winter.

Culture of the Toad-Flax Kinds.

Of the Toad-Flax *Antirrhinums*, the Common *Linaria*, *Antirrhinum Purpureum*, *Arvensis*, and *Triphylla*, are proper furniture for the common compartments of large pleasure grounds. The Purple *Linaria* particularly merit a place in every garden. All these sorts flower in June, and continue in succession till the end of summer, and are succeeded by abundance of seed in autumn.

The Common Toad-Flax grows wild by the way sides, that of banks, hedges, and pastures, as also the *Antirrhinum Arvensis*; but by culture in gardens they grow strong, and produce larger flowers.

All the sorts may be raised plentifully from seed, the same as the Snap-Dragons; and the perennial sorts also by parting the roots.

The Dalmatian *Linaria* and *Antirrhinum Trifidum* are somewhat tender, and some plants should be potted to be housed in winter, and some may be planted in warm dry borders; they flower in June and July, but rarely afford seeds here.

They are easily increased by slips and cuttings of their branches in summer, or by parting their roots in autumn.

•APETALUS *Flos*, i. e. Apetalous Flowers. By botanists, a flower is said to be Apetalous that wants the corolla, petals, or flower-leaves.

Of this sort are many of the amentaceous flowers, mosses, ferns, and grasses.

APIUM, Parsley, likewise Celery and Smallage.

By the laws of botany this genus comprehends all the sorts of Parsley and Celery, all of which are useful herbaceous biennials, of the kitchen garden.

Class and order, *Pentandria Digynia*.

Characters.] The flowers grow in compound umbels, each umbel composed of many florets, each floret of five petals, five stamina, two styles, and succeed by two seeds.

The species are,

¹APIUM *Petroselinum*.

Common Parsley, of which are two varieties, viz. Common Parsley with plane leaves. — Common Parsley with curled leaves.

²APIUM *Latifolium*.

Broad-leaved large-rooted Parsley.] Apium with a large carrot-shaped, sweet, eatable root, radical leaves divided into three serrated large lobes, and have very long foot-stalks.

³APIUM *Dulce*.

Sweet Apium, or Common Upright Celery.] Apium with upright leaves, supported on long erect foot-stalks, the folioles of the leaves composed of five serrated lobes.

Of this are two varieties, viz. Common Upright Celery with the stalks of the leaves fistular or hollow — Common Upright Celery with the stalks of the leaves solid; — known by the names of Hollow Celery, and Solid Celery.

⁴APIUM *Rapaceum*.

Turnep-rooted Spreading Celery.] Apium with a large round turnep-shaped root, spreading leaves on short foot-stalks, and the folioles of the leaves composed of five serrated lobes.

⁵APIUM *Graveolens*.

Rank-tasted Apium or Smallage.] Apium with the cauline leaves, having wedge-shaped lobes.

All these plants are herbaceous, and of hardy growth, and all of the biennial tribe, i. e. of only two years duration; the first year they produce only leaves, and attain perfection for kitchen use; the second spring they shoot up stalks, flower, and perfect seed, and in autumn perish, root and branch; so that they continue useful only one year, and a fresh supply must be raised annually from seed.

Some of the species, if sown very early, run to seed the same year, particularly the Celery.

First, of the Common Parsley.

The two varieties of the *Apium Petroselinum*, i. e. the Plane and Curled Parsley, are most useful culinary and medical herbs, their leaves being in great request for various kitchen uses, and their roots for medicine.

With respect to the properties of these two varieties of Apium; for use, their virtues are the same both for food and medicine; the plane-leaved sort is most commonly cultivated, but many prefer the curled kind, for these reasons, because its leaves are easily distinguished from those of the *Æthusa*, or Fool's-Parsley, a sort of hemlock, and a poisonous garden weed, which, while young, has great resemblance to the Common plane-leaved Parsley, see *ÆTHUSA*. Likewise, the Curled Parsley having larger and thicker leaves, and being curiously fimbriated and curled, appearing full and double, make a pretty appearance in its growth, and is greatly esteemed by cooks as a fine garnish to dishes. It is to be however remarked that this sort, as being only a variety, it will degenerate to the common plane sort, unless particular care is taken to save the seeds always from the perfect curled plants.

Both the varieties of Common Parsley are propagated by seed sown where the plants are to remain, annually in spring, for the plants are biennials, rising from seed in March, April, or May; continue useful until that time twelvemonth, then shoot up, stalk, perfect seed, and perish.

The season for sowing both varieties, is any time from the beginning of February until the beginning of May, though they will grow almost any time of the year; however, to have the plants come in for use by the time the old Parsley begins to run, it is proper to sow in February or March, and the plants will be fit to cut in May, or beginning of June.

It is most eligible to sow this seed in drills, as it will be more convenient to clean and gather the herbs for use. Where only a sufficiency is required for the supply of a family, it may be sown in a single drill along the edges of the borders, or quarters of the kitchen garden, and the plants will serve a double purpose, for they will form an edging, and give an air of regularity and neatness to the place, at the same time yield their produce plentifully; but for the supply of markets, the London gardeners sow it also in large plats, either in broad cast, and rake it in, or in shallow drills, eight or nine inches distance,

tance, and trim the earth evenly over it, near half an inch deep, and lightly rake the surface smooth.

This seed is so extremely slow in its vegetative motion, that its germination, or at least, the appearance of the plants, is not to be expected in less than five or six weeks.

All the culture the plants require is to be kept clean from weeds, and when they at any time grow faster than is wanted for use, as is often the case in private gardens, they, when grown rank and spreading, should be cut down close; this should be particularly practised in autumn, i. e. about Michaelmas, time enough for the plants to recover before winter, and numerous young leaves will rise from the roots, and form a thick compact edging.

To save Parsley seed, permit some rows of the one year old plants to stand, and they will shoot up their stalks in May and June, and ripen seed abundantly in July and August.

Of the Second Species, Broad-leaved large-rooted Parsley.

The *Apium Latifolium*, or Broad-leaved Parsley, is esteemed for its large roots, which are boiled and eaten as sauce to flesh meat.

These roots are white and carrot-shaped, being long, taper, and of downright growth, and often obtain the size of a middling carrot; they boil exceeding tender and palatable, are very wholesome, and may be used in soup or broth, or to eat like carrots and parsneps; the use of them is greatly recommended to persons that are subject to the gravel, and are used in decays of many kinds.

They are raised in great perfection by the London gardeners, who supply the markets with them in bunches.

Their season for use is from July until Christmas, or even till March.

The propagation of this species of *Apium* is by seed sown where the plants are to remain, annually in February, March, or April. Choose a spot of light rich earth, in an open exposure; sow the seed broad-cast, and rake it in: the plants will appear in April, and in May they will require to be thinned, and cleared from weeds, which may be performed either by hand or hoe, but the latter is most eligible, as it will stir and loosen the surface, which will be beneficial to the plants, cutting them out to about six inches distance.

In the latter end of July the roots will have attained a due size for use, when some may be drawn occasionally, but they do not

acquire their full growth until Michaelmas.

This sort is sometimes called Hamburg Parsley, because the plants are greatly cultivated in the gardens near that city.

Of the Third Species, Common Celery.

The *Apium Dulce*, or Common Celery, in both its varieties, is in universal esteem as a culinary and salad herb, and the stalks of its leaves are the only parts used, which are excellent in soups, and for stewing, and as an autumnal and winter salad herb, it surpasses many others. It may be obtained for use nine or ten months in the year, that is, from July until the middle or end of May; but the season of its greatest perfection, is from about the middle or latter end of August till Christmas, or even till March, if the winter do not prove severe.

Both the varieties are of upright growth, and obtain two feet and half in height, which, by the culture of planting them out in trenches, together with several repetitions of earthing up their stalks as they advance in stature, they become very white, tender, and palatable, which otherwise would be tough and rank-tasted.

The Hollow Celery is the original variety, having been long known before the solid kind, the stalks of the latter having no hollow or vacancy in the middle; the former have, and is the principal difference, for they possess equal properties for general use, though the solid kind is often preferred for soups and stewing; but we however do not recommend it for a general winter crop, because it will not endure frost so well as the common Hollow Celery, nor for market service, it being very brittle, will easily break in washing and bunching up, as practised by the London gardeners, who bind six, eight, ten, or twelve heads, placed singly, but close together, in a flat spreaded bunch.

Their propagation and culture is as follow.

They are propagated by seed sown in the spring, and when the plants have attained six or eight inches in height, they are to be transplanted into trenches, in order to be earthed up on each side as they advance in growth, to blanch or whiten their stalks, to render them crisp and tender. See *Transplanting* and *Earthing them up*.

A fresh supply of plants must be raised annually, for the plants continue useful but one year.

The proper periods of time for sowing it, are,

are, that, if a regular succession of plants is required, eight or nine months in the year, it is necessary to perform three different sowings from the beginning of March until the middle of May.

As for example, if it is intended to have Celery for use as early as possible in summer, i. e. in July, sow some seed the first week in March, on a warm border; or, to bring the plants more forward, in a slender hot-bed; or if you are anxious to have very early Celery, some seed may be sown in the middle of February; but as these very early sown plants are apt to pipe, or run for seed the same year, before they attain half their perfection, a few should only be raised.

But for the general or principal crops, to come in for autumn and winter service, that is, in August or September, and continue in perfection till Christmas or spring, the seed should be sown towards the latter end of March, or in the first or second week in April, in a bed of natural earth, in an open exposure, and if a little more is sown in the latter end of the last named month, or in the first or second week in May, it will furnish a latter crop to come in for use the beginning of November, and continue good until the latter end of March; and by planting some in shallow trenches about Michaelmas, and in October and November, they will be fit for use in March and April, and continue without running till the middle or latter end of May.

We observed above, that the early crop may either be sown upon a warm border of natural earth, or upon a hot-bed of slender structure; by the latter practice, the plants may be so forwarded as to be fit to transplant into trenches sooner by three weeks or a month, than those raised in the natural ground; a small bed, about eighteen or twenty inches depth of dung, will be sufficient, which may be sheltered either with a small frame, or occasionally with mats supported on arches; lay thereon five or six inches of rich light earth, sow the seed on the surface, and cover it near a quarter of an inch deep; when the plants appear, admit the full air freely in mild days, but shelter them with a glass or mats on nights, until they acquire some strength, and give frequent light watering; and when the plants, of either sowing, are two inches high, some of the stoutest should be pricked out into a bed of rich earth, in a sheltered situation, three inches

apart; or to bring them still more forward, some might be pricked upon a slender hot-bed, occasionally sheltered with mats, giving water and occasional shade till they have struck root; and if rain do not fall, refresh them frequently with water, as you shall see necessary.

Those that were first pricked out, will, in May or the beginning of June, be five or six inches high, when some of the strongest should be transplanted into trenches, in order to their being blanched. See *Transplanting into Trenches*, next page, &c.

With regard to sowing the main and latter crops, observe the following directions.

At the times above noticed, make choice of a spot of rich light earth, in an open situation, and let it be then neatly dug, and divided into one or more beds; but one small bed is sufficient for private use, which should be three feet and half wide, making the surface level and smooth; this done, the seed may either be sown on the surface, and raked in lightly, or otherwise first rake the surface fine, then sow the seed, and sift earth over it near a quarter of an inch thick; or if the surface being first raked smooth as above, then, with the back of a rake, shove the earth from off the surface a quarter of an inch deep into the alley; sow the seed, and then with the rake turned the right way draw the earth on the bed again, with a kind of jerk, that it may spread and cover the seed equally in every part.

When the plants of either sowing are come up, they should, in dry weather, be frequently watered; do not omit this, particularly whilst the plants are young.

When the plants of each sowing are about three or four inches high, it is adviseable to thin the seed-bed by pricking out a quantity of the strongest into an open rich spot, properly dug and divided into beds three feet and half wide, taking opportunity, if possible, of moist weather, and prick the plants therein, in rows six inches asunder, and three or four inches distant in each row, giving water, which, if dry weather succeeds, should be occasionally repeated, till they strike fresh root, and in which bed they are to remain five or six weeks to acquire due strength, previous to their being transplanted into trenches, in order for blanching.

The same seed-bed will afford three, four, or more different drawings to prick out as above, which, by observing to thin out the largest

largest regularly each time, before they draw each other weak by close standing, and prick them in beds till the ground intended for the trenches is at liberty, they will be advancing in their growth, and will be considerably better prepared, than such that have remained all the time in the seed-bed.

Transplanting them into the Trenches.

The season for transplanting these plants into the trenches for blanching, is occasionally from the middle of May until the latter end of October, or even middle of November, according to the forwardness of the plants, time they are required for use, and the time it is intended they shall continue.

Observe, that when the plants are from about six to ten or twelve inches high, they are of a proper size for transplanting into the trenches.

It is necessary always to make, at least, three different plantations, allowing the distance of three weeks between each time of planting; but when the plants are required for use as early in summer as possible, and to be continued as late in spring as the middle or latter end of May, it is eligible to plant five or six different crops, allowing the distance of time abovementioned between the planting each separate crop; and observe that the crops intended principally for spring use, i. e. March, April, and May, should not be planted in the trenches until October and beginning of November.

The manner of making the trenches, and transplanting the plants therein, is as follow.

Make choice of a rich spot of ground, in an open quarter, and if there be any weeds, hoe the ground, and rake them off; then, with a line and spade, mark and chop out the trenches cross-ways the piece of ground, each trench twelve inches or one spade wide, and allow a space of three feet between trench and trench, that there may be sufficient scope to have a due portion of earth to land up the plants a proper height; the trenches being thus marked, then proceed to dig them out to form the cavity for the reception of the plants; observe to dig out each trench a moderate spade deep, without taking out any shovelling, laying the spits of earth alternately to the right and left in the spaces between, levelling it neatly, and beating up the edges firm and strait, and then let the bottom be properly dug and levelled; or if the ground is poor, you may first spread therein two or three inches depth of rotten dung, and dig it in four or five inches deep.

The trenches being ready, get the plants and trim them by cutting off the ends of their roots, and the tops of the straggling leaves; then plant one row exactly along the middle of each trench, placing the plants four or five inches distance; and directly give a hearty watering out of a pot with the rose on, which, if showers do not fall, should be repeated every other evening at least, till the plants have taken fresh root.

Do not plant out many of the very early plants, i. e. those sown in February, or early in March, because they are apt to pipe almost as soon as they are blanched.

When it happens that the plants intended for the late crops have stood so long in the seed or pricking-out bed, as to become rank, and grown so close as to draw each other up weak; in order to retard their running up tall, and to obtain them of short and robust growth against October and November, to plant in shallow trenches, it is advisable, in August or September, either to cut them down low to shoot out again, or transplant them in rows nine inches distance.

Earthing, or Landing up the Plants.

As we before noticed, these plants, in order to whiten or blanch the stalks, and render them crisp, tender, and of a grateful flavour, should, according as they rise in height, be earthed or landed up on each side, using for that purpose the earth that was dug out of the trenches, and when that is expended, that in the spaces between them must be dug, broken, and used repeatedly as the plants advance in growth.

The proper period to begin this work of earthing, is when the plants are about ten or twelve inches high, and which should be repeated every fortnight or three weeks, as you shall see necessary, during their principal growth.

In performing this work, regard must be had to break the earth moderately fine, and trim it up to the plants with attention, not to break the stalks of the leaves, nor force the mould into their hearts. At the first time of earthing, you may land them three, four, or five inches, according to the size and height of the plants, observing the same rule at each time of earthing them, till they are by degrees landed at least twelve, but if fifteen or twenty inches, the better; which, if the soil is rich, and somewhat moist, those of the main crop that are planted out in the end of June, or in July, sometimes make such progress, that if properly followed up with earth, they

they will, by October, be blanched eighteen inches, or near two feet in length.

The above work of earthing is to be continued to the latter crops, occasionally, until Christmas, or as long as the plants continue to grow in height during the winter; at which season, i. e. November and December, it is proper to land them up pretty near their tops, in case of hard frost setting in, which often destroys such part of the plants as are out of the ground, which, if of considerable length, would occasion the decay of most of the other parts within the earth.

In performing the different landings up, let it always, if possible, be done when the plants are dry, otherwise they are apt to become spotted and cankered.

Of taking up the Plants for Use.

Some of the first landed up plants, if they were planted in trenches in May or beginning of June, will be fit to take up in July, for when these early plants are blanched five or six inches in length, you may begin to take them up; for if they were sown pretty early, they rarely continue long before they begin to pipe, and soon become useless.

But the plants of the main crop will not be blanched any considerable length till the latter end of August, or beginning of September, but will not acquire their full perfection until October, as we before observed. However, where there is a demand for the plants, you may begin to take some up when they are whitened six or seven inches, as, if properly followed with earthing, they will be encreasing every day in length in the blanched part.

In winter, at the approach of very severe frost, it would be of particular advantage to cover some of the rows of the main crop with dry long litter, to save the plants, and prevent the ground being frozen hard, that the plants may readily be dug up when wanted.

Likewise, at the approach of hard frost, a quantity of the plants may be taken up for the use of a family, and laid in some dry earth in a shed, or other sheltered place.

Another Method of Planting Celery in Trenches for Blanching.

There is a method of planting out the Upright Celery in trenches, but little known or practised in these parts; the manner of it is as follows:

Having fixed upon an open piece of ground, then with a line and spade cut or mark out a bed, or rather trench, six feet wide, cross-ways the ground; this done, begin at one

end, and proceed to dig out a cavity the above width and length, one spade deep, laying the spits of earth to the right and left in a ridge along each side of the said cavity or trench, beating it up in front that it may not slip down, and when the trench is thus dug, loosen and level the bottom, and if dung is needful, let some be added, and dig it into the bottom four or five inches deep.

When more than one of such trenches are to be made, allow a clear space of six feet between trench and trench, to contain the earth dug out, and to have a sufficiency to land up the plants.

These trenches being prepared as above, then, having the plants and trimming them as before directed, proceed to plant them; but observing they are here to be planted in rows cross-ways the trench, the rows to be a foot asunder, and the plants to be set six inches distant in each row, and giving water as advised in the other method.

When the plants are of due height for earthing up, the earth that was thrown out of the trenches is to be first used, then that of the spaces; break it fine, and with the spade trim it in carefully between the rows of plants, in equal portions from each side of the trench, landing them up a due height, which is to be occasionally repeated, observing the same rules as advised in earthing the plants.

In landing up the plants that are planted in the above method, it will be of advantage, when they have attained a large growth, to be furnished with a couple of thin boards, six feet long; these are to be used at the time of earthing, to slip into the spaces between the rows of plants, to keep the stalks and leaves up close just till the earth is put in, placing them close to the plants; then trim in the earth between the boards, and when one space is thus earthed, draw out the boards and place them in the next, and in that manner proceed in earthing the several rows in every such trench.

Culture of the Fourth Species, Turnep-rooted Celery.

The *Apium Rapaceum*, or Turnep-rooted Celery, is esteemed principally for its root, which acquires a globular turnep-like form, and by culture becomes very white and tender, and is used for the same purposes as the Common Celery.

The leaves of this sort spread out somewhat horizontally, and rarely exceed ten or twelve inches in length, which, when blanched,

Blanched, may be used like the Upright Celery.

It is propagated by seeds, in an open rich spot, in March or April, sowing it as directed for the common sort, and when the plants are an inch or two high, thin them to three inches; and when they are four or five inches in height, transplant them into shallow trenches; previous to which, dig the ground all over, one spade deep, then with an hoe draw drills three inches deep, and eighteen asunder, and set the plants therein, six inches distance, and give water.

When the plants are advanced nine or ten inches in growth, observe the progress of the roots, and when they have acquired a tolerable size, draw earth up to each side of the row of plants, three or four inches high, which one earthing is sufficient to improve, the roots, which will be fit to take up for use in three or four weeks after.

Of saving Seed of this Species.

When it is intended to save Celery seed, leave a few of the finest plants in the places where they were planted out for blanching; they will shoot up their flower-stems in May and June, flower in July, and ripen their seeds in August, when the stalks should be cut and set in the sun a week to harden, then beat out the seed, and put it up in bags.

Fifth Species, the Smallage.

The *Apium Graveolens*, or Smallage, is a common weed, bearing great resemblance to Celery, inasmuch that the latter is by some supposed to be a variety of the former, raised to its present state of perfection by long culture; but I greatly doubt this, since both sorts retain their difference from seed.

This sort is used in medicine, but rarely for culinary purposes, except sometimes by poor country people to put in broth, or potage, in default of other herbs.

It grows wild in moist places, and is seldom cultivated in gardens; but if wanted, it may be raised plentifully from seed in the spring.

APOCYNUM, Dog's-Bane.

This genus comprehends hardy herbaceous perennials, and tender shrubby exotics, all of the flowery tribe, obtaining from two to five or six feet stature, adorned with simple leaves, and monopetalous bell-shaped flowers in clusters.

Class and order, *Pentandria Digynia*.

Characters.] CALIX is monophyllous, five-parted at the edge, and permanent. COROLLA is monopetalous, bell-shaped, and

five-parted at the brim, and five oval nectariums at bottom. STAMINA, five filaments, and bifid antheræ. PISTILLUM, two germina, two small styles, and globular stigma. PERICARPium, two capsules, containing many seeds.

The species are,

¹APOCYNUM *Androsæmi-folium*.

Tutsan-leaved Canada Apocynum.] Apocynum with upright herbaceous stalks, a yard high; large oval, smooth, stiff leaves, growing opposite by pairs, and the stalks crowned by cymose umbels of white flowers, having purplish nectariums.

²APOCYNUM *Cannabinum*.

Dwarf Canada Dog's-Bane.] Apocynum with upright herbaceous, reddish stalks, two feet high, oblong smooth leaves, set opposite by pairs, and the upper parts of the stalks terminated by greenish-white flowers in panicles.

³APOCYNUM *Venetum*.

Venetian Willow-leaved Apocynum.] Apocynum with erect herbaceous stalks, two feet high, oval spear-shaped smooth leaves, placed opposite by pairs, and the top of the stalks adorned with large flowers, collected into bunches.

Varieties of this.] Venetian Apocynum with purple flowers—with white flowers.

⁴APOCYNUM *Frutescens*.

Shrubby Upright Ceylon Apocynum.] Apocynum with a shrubby, erect, branchy stem, obtaining five feet in height, the branches adorned with oval spear-shaped, smooth, shining leaves, set opposite by pairs; and flowers collected into small bunches, having an acute corolla, and hairy jaws.

Varieties.] Shrubby Apocynum with purple flowers—with yellow flowers.

⁵APOCYNUM *Reticulatum*.

Climbing Veined-leaved Indian Dog's-Bane.] Apocynum with a twining perennial stalk, climbing twenty or thirty feet high, oval, very much veined leaves, by pairs opposite; and small bunches of flowers from the sides of the branches.

Varieties.] With purple flowers—greenish flowers—with white flowers.

For other species of Dog's-Bane, see ASCLEPIAS, PERIPLOCA, and CYNANCHUM.

The three first species are hardy herbaceous perennials; the roots are fibrous, and very creeping; the stalks rise annually from the root in spring, and perish in autumn; the leaves are simple, and pretty large, which,

as well as the stalks, abound with a milky juice: the flowers are formed each of a single hollow, bell-shaped petal; those of the *Apocynum Venetum* are considerably the largest and most beautiful: they all flower in July and August, but rarely perfect seeds in Britain.

These three sorts and their varieties are proper furniture for the common compartments of the pleasure ground.

The propagation of these three species is easily effected by their creeping roots, in autumn or spring, either by dividing the main root, or by joints thereof.

The *Apocynum Frutescens*, and Climbing Dog's-Bane, are tender exotics of the stove; the first has most claim to attention.

They may be propagated by seeds procured from abroad, and by cuttings and layers, either of which must be assisted by a hot-bed, and the plants are to be potted and always retained in the stove.

AQUATICÆ Planta, Aquatic Plants, i. e. such that grow in or near waters, either rivers, ponds, watery ditches, or other very marshy places.

AQUILEGIA, Columbine.

The plants are hardy, herbaceous, flowery perennials, that obtain from one to three feet stature, adorned at top with many pentapetalous nectarious flowers.

Class and order, *Polyandria Pentagynia*.

Characters.] **CALIX** none. **COROLLA**, five oval, spear-shaped, spreading petals, and alternately with these are ranged five hollow and horned nectariums, their lower part lengthened to a long incurved tube. **STAMINA**, numerous filaments, and erect antheræ. **PISTILLUM**, five oval germina, five subulate styles, and simple stigmas. **PERICARPIUM**, five erect cylindrical capsules, containing numerous oval shining seeds.

There are but three species, which are,

¹**AQUILEGIA Hortensis**.

Garden, or Common Columbine.] *Aquilegia* with upright stems, a yard high, dividing into many erect branches, leaves composed of many lobes, growing by threes, and all the branches terminated by the flowers, which have incurved nectaria.

Varieties of this are numerous, and singularly curious, which are,

Common Columbine with flowers composed of five petals, ranged alternately with five nectaria, as expressed in the characters.

Common Columbine with flowers composed of double petals, and nectaria ranged alternately.

Common Columbine with flowers, having no visible nectaria, and composed principally of oval petals, of which there are single and very double flowers; commonly called Rose Columbines.

Common Columbine, having no visible nectaria, and composed principally of sharp-pointed petals, expanding like a star, of which there are single and perfectly double flowers, commonly called Starry Columbine.

Common Columbine with flowers, having no petals, being composed entirely of nectaria, of which there are single, double, and trebly double flowers, having numerous nectaria, placed one within another, in a curious manner.

Common Columbine with inverted flowers.

Of each of the above varieties, there are blue flowers—white flowers—red flowers—purple flowers—flesh-coloured flowers—ash-coloured flowers—chestnut-coloured flowers.—Of variegated kinds there are, blue and purple flowers—blue and white flowers—with red and white flowers—blue and white flowers—with finely striped flowers—with flowers having one part plain or self-coloured, the other curiously striped and spotted with different colours.

²**AQUILEGIA Vulgaris**.

Wild Mountain Blue Columbine.] *Aquilegia* with upright slender stems, two feet high, dividing into many slender erect branches, many-parted leaves, and large single blue flowers terminate the branches, and with erect nectaria, and short spear-shaped petals.

This grows wild in many places in woods and hilly grounds.

³**AQUILEGIA Canadensis**.

Canada Dwarf Early Columbine.] *Aquilegia* with upright stalks, a foot high, dividing into slender erect branches, each terminated by a single flower of a red colour, with a yellow middle, having erect nectaria, and stamina longer than the corolla.

All these species and respective varieties are hardy herbaceous perennials; the roots are fibrous, and the leaves and flower-stems rise annually from the root in spring; the leaves are branching, and composed of many lobes, growing generally by threes; the stems divide into many branches, each terminated by the flowers, which are large, numerous, and very showy, appearing in April, May, and June, and ripen seeds plentifully in August and September.

The *Aquilegia Hortensis*, or Garden Columbine,

bine, in all its varieties, are choice furniture for pleasure grounds of any extent, their flowers being large and numerous, and assuming many curious structures, forms, sizes, colours, and variegations, as to be extremely conspicuous and ornamental in a garden, and those of all the double variegated and striped kinds particularly have singular elegance; and in short, all the varieties are capable of forming a most agreeable diversity, and they prosper freely in any common soil and exposure, but make the finest appearance in an open situation.

It is remarkable that all the different varieties of this species, in regard to structure, form, size, colour, and variegations of the flowers, are often obtained from the seed of the same plant.

All the varieties of this species flower in the end of May, and in June.

The *Aquilegia Vulgaris* have no striking beauty, but the flowers being large, will form a variety in the common borders in May and June.

The Canada Columbine merits culture principally for its early bloom, which generally appear in April.

Propagation, Culture, &c.

First of the *Aquilegia Hortensis*. All the varieties of this sort may be raised plentifully from seed, and by dividing their roots.

The seed may be sown either in autumn or spring, in a bed or border of common light earth; dig the ground neatly one spade deep, sow the seed moderately thick on the surface, and rake it in, and the plants will appear in April or May, giving occasional water and weeding until June, July, or August, according to their size; then prick them out upon another bed in rows nine inches distance, and give occasional watering during the hot weather. Next summer the plants will flower, but not strong; when the best kinds should be marked, in order to be removed in autumn into the most conspicuous compartments, where they will flower strong, and in their utmost perfection the year following, and continue several years.

In order to keep up a succession of fine flowers, a supply of plants should be raised from seed every two or three years, because the old plants discover a degeneracy, that often, from the fullest doubles, and elegant variegations, become single, and of plain colours.

By parting the roots, any variety may be

increased; but this should be performed always upon the young plants of two or three years old, before they degenerate, which may be done in autumn or spring.

In saving seeds of this species, gather it always from the plants that exhibit the finest flowers.

The other two species, Mountain and Canada Columbines, are to be propagated in the same manner as the garden kinds.

All the culture necessary for the several kinds, is to keep them clean from weeds in common with other plants, and to cut down their decayed stems in autumn.

ARALIA, Berry-bearing Angelica, and Angelica-Tree.

This genus comprehends two herbaceous perennials, and one woody plant, of the tree kind.

Class and order, *Pentandria Pentagynia*.

Characters.] CALIX, globular umbel of flowers, having a small involucre, and very small cup to the florets, resting on the germen. COROLLA, the florets of the umbel have five oval petals. STAMINA, five filaments, and roundish antheræ. PISTILLUM, a roundish germen below the calix, five short styles, and simple stigma. PERICARPIUM, a roundish striated berry, containing five seeds.

The species are,

¹ARALIA *Racemosa*.

Leafy-stalked Herbaceous Canada Aralia.]

Aralia with an upright, smooth, branching, leafy stem, obtaining three or four feet stature, adorned with large leaves, composed of many oval serrated lobes, and flower-stalks rising from the angles of the leaves, terminated by round umbels of whitish flowers.

²ARALIA *Nudicaulis*.

Naked stalked Herbaceous Virginia Aralia.]

Aralia with an upright naked, or leafless stalk, a yard high, large branching leaves, of two or three divisions, each division composed of five serrated lobes, and rise directly from the root, and between them the stalks, crowned by round umbels of whitish flowers.

³ARALIA *Spinosa*.

Thorny Tree-like Virginia Aralia, or Angelica-Tree.] Aralia with a tree-like branching stem, growing ten or twelve feet high, defended by strong spines, large, long, decomposed, spinous leaves, composed of many wings, each wing of many oblong lobes, and large, loose, greenish-yellow umbels of flowers terminate all the branches.

All these plants are natives of America, but grow freely here in the full ground.

The appellation of Angelica to these plants, is from their similarity of growth, and the young leaves forming a cluster at the ends of the stem and branches, like those on the same parts of the Common Angelica.

The *Aralia Racemosa* and *Nudicaulis* are herbaceous perennials; the roots are fibrous, and creep considerably, and the stalks rise annually from the root, produce their large umbels of flowers in June and July, and are succeeded by plenty of seed in clusters of small black berries, ripe in September and October.

These two species assuming a large branching majestic growth, are proper furniture for the compartments of large shrubberies, and to embellish those of wilderness works, and the borders of wood-walks, &c.

Their propagation is by seed, and by dividing their roots.

The seed, if sown in autumn, in a bed of light earth, will rise freely in the spring, and in autumn transplant the plants where they are to remain.

By roots they encrease exceedingly, which may be parted in autumn when the leaves decay.

The *Aralia Spinosa*, or Angelica-Tree, is deciduous in leaf. It is a plant of singular appearance in summer, when cloathed with its large, long, doubly branching, many-lobed leaves, and claims a place in the most conspicuous parts of the shrubbery.

It flowers in August, but rarely perfects seed in England.

The propagation of this species is by seed, and by planting pieces of its horizontal roots.

The seed is procured from America. Sow it as soon as it arrives, in spring, in pots of light earth, and cover it half an inch deep, and if they are plunged in a moderate hot-bed, it will facilitate their germination; but in default of this, plunge the pots in a dry warm border, give occasional light waterings and shade in hot sunny days, and probably the plants will appear the same year; but if this is not effected by June, move the pots under a shady hedge or wall for the remainder of the summer, and in October place them in a garden frame, to have occasional shelter from frost during winter, in which let them remain until March; then plunge them in a warm border, and if the plants did not come up before, they will now appear, giving wa-

ter occasionally, and remove the pots to the shade in summer, and into a frame again in winter, to continue until the latter end of March; then transplant them, some separately into small pots, others in a bed of light earth, in a sheltered situation in the nursery: those planted in the pots are designed to be moved to shelter in winter, because the seedling plants are tender the first two or three years; some shelter should also be bestowed the first winter upon those in the full ground, when the frost is very severe.

When these plants are three or four years old, or two or three feet high, they may be transplanted into the shrubbery.

To propagate them by roots, cut off pieces of the horizontal ones in spring, and plant them in pots, which plunge in a hot bed, and they will send out fibres below, and shoots above.

Likewise, by separating some of the roots from the plant in spring, permitting them to remain in the ground, they will also send up several shoots or stems.

ARBOR, a Tree. A perennial plant, rising with a simple, woody, and durable stem or trunk, to a great height and substance.

This definition of a tree is principally the substance of what naturalists advance to distinguish a tree from a shrub, which is supposed to be of lesser growth, and for the general part to have several stems; and from herbaceous plants, whose stems are soft, often succulent, and mostly rise in spring, and perish in autumn, though this is not general.

But in regard to the distinction between trees and shrubs, it is not universally obvious. Nature, says Linnæus, has put no limits betwixt trees and shrubs; for to say that trees are taller than shrubs, is in effect saying nothing, unless a certain fixed immutable standard were previously established. Besides, every thing respecting dimensions is so variable in its nature, and depends so much upon difference of climate, soil, and culture, that no certain standard or boundary can with propriety be fixed between trees and shrubs, since the same plant, in different countries, often assume very different growths; thus the *Arbutus*, and Laurel, in warm climates, grow to large trees; in this country are generally considered as shrubs.

The only definition therefore that can be made, is, that, for distinction sake, shrubs may be considered as such, which either rise with

with several stems from the root, or that the main stem divide near the root into several smaller ones. See *FRUTEX, a Shrub*.

ARBOURS.

These are departments in gardens formed with various sorts of trees and shrubs, in such order as to enclose a certain space, to form a kind of recess and shady retreat from the walks, in the heat of summer.

They were in great repute formerly, and were commonly formed of ever-greens, very often of yews, planted very close, the sides trained erect, six, eight, or ten feet high, and the top formed like a vault, or trained arch-ways, over an arched frame or lattice-work, of wood or iron, and arched openings or arcades were curiously formed on the sides, and the whole was thorn or clipped annually, to keep them in due order, which often appeared very ornamental, according to the ancient style of gardening.

These kind of Arbours were also often formed of deciduous trees, particularly those of the elm, and sometimes with hornbeam, beech, and limes, which were constantly sheared every summer.

The figure of these Arbours, both of the ever-green and deciduous kinds, were either square, hexagonal, octagonal, or round; and their dimensions were from ten to fifteen feet in width and height; the tops were formed either pavillion, turret, or dome fashion, and sometimes terminated by a globe, pyramid, or other figure, formed of the extreme branches.

Covered Arbours or Bowers may be formed very quickly, even in one season, with several sorts of shrubby climbers, some of which will advance fifteen or twenty feet in one summer. See *CLIMBING PLANTS*.

When it is designed to form an Arbour, it should, if possible, be erected upon a somewhat rising ground, for the greater advantage of free air, and to enjoy the prospect of the garden and adjacent country.

An Arbour is sometimes formed in the head of a single tree, particularly that of the elm, when the trunk has divided at the height of ten or twelve feet, into several lesser spreading stems, to admit of erecting a small platform between, cutting down the large boughs, and training the pliable branches arch-ways over lattice-work, till those of each side meet; so continue to shear the sides annually, and the top may either be cut, or permitted to grow up.

Rural Arbours are sometimes formed thus: plant some of the tallest growing flowering shrubs round the inside, to form the dimensions of the Arbour; then, on the outside of these, plant others of somewhat lesser growth; so continue three or four ranges, diminishing gradually in stature from the Arbour outward, permitting the whole to take their natural growth; so that at a distance it will assume the appearance of one of the common shrubby clumps.

The bottom of Arbours should be gravelled, and garden-chairs placed there in summer, which should always be housed in winter.

ARBUTUS, the Strawberry-Tree.

This genus furnishes most beautiful ever-green shrubs for the shrubbery, remarkable for producing fine clusters of scarlet fruit, like strawberries, hence they derive the appellation Strawberry-Tree.

Class and order, *Decandria Monogynia*.

Characters] *CALIX* is small, five-parted, permanent, and placed under the germen. *COROLLA*, a single pitcher-shaped petal, five-parted, and revolute at the brim. *STAMINA*, ten short filaments, and bifid antheræ. *PISTILLUM*, a globular germen, cylindric style, and thick obtuse stigma. *PERICARPIUM*, a roundish berry of five cells, containing small hard seeds.

The species are,

¹*ARBUTUS Unedo*.

Common Arbutus, or Strawberry-Tree.] *Arbutus* with an erect tree-like woody stem, oblong oval smooth leaves, sawed on the edges, and berries having many seeds.

Varieties of this are,] *Common Arbutus* with large oval fruit.—*Common Arbutus* with round fruit.—*Double-blossomed Common Arbutus*.—*Scarlet-flowering Common Arbutus*.

²*ARBUTUS Andrachne*.

Andrachne, or Oriental Broad-leaved Arbutus.] *Arbutus* with an erect tree-like woody stem; oblong, oval, smooth leaves, having entire edges; and berries having many seeds.

³*ARBUTUS Uva Ursi*.

Uva Ursi, Bear-berry, or Dwarf Arbutus.] *Arbutus* with shrubby, very branchy stalks, about two feet high; oval, thick, smooth, entire leaves; greenish-white flowers in clusters at the ends of the branches, and roundish berries.

Varieties.] *Uva Ursi* with black berries.—*Uva Ursi* with red berries.

All the above species and respective varieties are hardy exotic ever-greens; the two former are of a tree-like growth, and the other is a dwarfish shrubby plant. They will prosper in any common soil of a garden.

They are all closely adorned the year round with simple leaves, and produce flowers and fruit in small loose clusters.

The Common *Arbutus* and varieties are some of the most elegant ever-greens of our shrubberies; they are natives of Spain, Italy, and some parts of Ireland, where they obtain twenty or thirty feet stature, with trunks of considerable substance.

These varieties, in this country, often grow twelve or fifteen feet high, assuming full and regular heads, and all the young shoots a fine red colour, the whole closely adorned with moderate-sized, oblong, sawed leaves, placed alternate, and the trees are fully garnished with them at all seasons, and produce whitish flowers in numerous small clusters annually in October and November, succeeded by abundance of strawberry-like fruit; but these do not attain maturity in less than twelve months, when they assume a scarlet colour; so that those of each year's bloom ripen next year in November, by which means there are annually flowers, and ripe fruit upon the trees at the same time; which, together with their numerous leaves on red foot-stalks, effects one of the most singularly beautiful contrasts in nature.

The oval and round fruited varieties are the sorts most commonly cultivated, the former of which rather obtains the largest growth, and produces the largest flowers and fruit.

The double-blossomed kind having only two series of petals; its doubleness is not very conspicuous.

The scarlet kind, when in bloom, forms a pretty diversity, in assemblage with the other varieties.

The *Andrachne*, or Oriental *Arbutus*, assumes a larger growth than any of the preceding sorts, and branches out irregularly; the leaves are large, and with the edges entire, but produces flowers and fruit like the Common *Arbutus*.

This sort having fine large leaves, makes a noble appearance at all seasons.

The flowers of all these varieties are produced in small loose clusters, each separate flower is small, and formed universally of a single hollow petal, bellied below, pitcher fashion; the whole, except the scarlet kind,

assume a greenish-white colour, and the fruit succeeds the flowers in clusters.

The fruit are berries, in shape, size, and colour resembling large scarlet strawberries, though generally much larger, and grow three, four, five, or more in clusters, remarkably beautiful to appearance, but unpalatable to eat.

The *Uva Ursi* is a small bushy shrub, a native of the mountainous parts of the continent of Europe, and is retained in many gardens for the sake of variety.

Use in Gardens, Propagation, &c.

All the varieties of the Common *Arbutus* and *Arbutus Andrachne*, are some of the finest ever-greens that can be seen, and are well adapted to occupy the most conspicuous places in shrubberies, either in assemblage towards the fronts of clumps, or to be placed detached on grass ground.

In whatever mode of planting it is designed to employ them, place them so much detached as to appear conspicuous at all times, and permit them to take their own natural growth.

The best season for transplanting all the sorts, is the end of September, October, and beginning of November, or in March and April.

The propagation of all the species is effected most commonly by seed; they will also sometimes grow by layers and cuttings, though rather reluctantly; but the seed grows freely, and from which the handsomest plants are always obtained. Observe however, that, to continue the double-blossomed and scarlet kinds with certainty, it must be effected either by layers, cuttings, grafting, or inarching; for these varieties will not retain their difference from seed.

From the seed of either the common oval and round fruited kinds, some of both sorts may be expected; that of the former is rather to be preferred for sowing.

The berries containing the seed may be had of the nurserymen in October, November, and December; and the seed may either be then sown in pots, and sheltered in a frame all winter, or may be preserved in dry sand until March, and then sown in pots of light earth, and covered about a quarter of an inch deep; then, if the pots are plunged in a hot-bed, it will so greatly forward the germination of the seed that the plants will rise in a month or six weeks, when they must have plenty of air, moderate waterings, and by degrees

greens inured to the full air, when the pots should be plunged in the common ground until October, and then placed in a greenhouse or frame, to have shelter from frost, till March; at which time it is adviseable to transplant the seedlings singly in small pots, which, if directly plunged upon a slender hot-bed, shielded and shaded occasionally with mats, giving moderate waterings, they will quickly take root and set to growing, when the pots may be plunged in a bed of common earth in a sheltered place, to remain two or three years, indulging the plants with larger pots, and protection from severe frost, till they are about two feet high; then transplant them, with the balls of earth about their roots, into the full ground.

To propagate them by layers, it must be performed on the young shoots, which rarely emit roots in less than two years.

Cuttings will emit roots by the aid of heat. Plant a number of the short young shoots in pots, and plunge them in a substantial hot-bed of tan or dung.

Inarching or grafting them is performed in the usual way, upon stocks of any of the varieties.

ARCTOTIS.

This genus consists of four shrubby perennials, of tall and very branching growth, and an herbaceous acaulis plant, all flowery exotics of the green-house.

Class and order, *Syngenesia Polygamia Neceffaria*.

Characters.] CALIX, is a round, imbricated, scaly cup. COROLLA, is compound and radiated; the middle composed of numerous male, funnel-shaped, five-parted, reflexed florets, and many long, flat, female florets compose the border or radius. STAMINA, in each male floret are five filaments, having short antheræ. PISTILLUM, in the female florets, a trigonous downy germen, simple style, and two oval stigma. PERICARPIUM none, and a single seed in each female floret.

The species are,

¹ARCTOTIS *Aspera*.

Rough-leaved Golden Arctotis.] Arctotis with an upright, branching stalk; oblong, deeply sinuated, winged-like, hairy leaves; the segments oblong and indented, and large golden yellow flowers, having a fertile radius.

²ARCTOTIS *Angustifolia*.

Narrow-leaved Arctotis.] Arctotis with an erect, branching stalk; narrow, spear-shaped, stiff, entire leaves, indented on the

sides, and pale yellow flowers, having a fertile radius.

³ARCTOTIS *Calendula*.

Sea Ragwort-leaved Arctotis.] Arctotis with an erect, branching stalk; oval, lyre-shaped, indented leaves, with blackish denticles, and large sulphur-coloured flowers, having a sterile radius.

⁴ARCTOTIS *Plantaginea*.

Plantain-leaved Arctotis.] Arctotis with an upright, branching stalk; ovate-spear-shaped, indented, nervous, running leaves, embracing the stalk; and large golden yellow flowers, having a fertile radius.

⁵ARCTOTIS *Acaulis*.

Stalkless Dwarf Arctotis.] Arctotis without stalk, lyre shaped, sinuated leaves from the root, the foot-stalks of the flowers rise between the leaves, supporting large golden flowers.

The four first species obtain four or five feet stature, having erect, thick, shrubby-like, perennial stems, which divide into many luxuriant tender branches, terminated by large, compound, radiated, yellow flowers, appearing in summer, and often continue in succession during autumn and winter, and make a pretty appearance.

The *Arctotis Acaulis* is a low plant, the flower stalks rarely exceed six inches in height, but support fine large radiated flowers in April or May, and often afford ripe seeds.

They are all exotics of Africa, and require the protection of a green-house in winter, so must always be kept in pots.

The propagation of the shrubby sorts is easily effected by cuttings of the branches or shoots any time the beginning of summer, either in pots, or a bed of light earth, giving occasional shade and water, and they will be rooted in six or eight weeks, when they should be planted in separate small pots, and managed as other green-house plants.

The dwarf sort may be raised from seed in spring, and by slips from the roots.

ARISTA, the awn, or sharp beard or point issuing from the husk or scaly flower-cup of the grasses, as that of the common barley and other corn.

ARISTOLOCHIA, Birthwort.

This genus comprehends herbaceous perennial exotics of the common ground and green-house, adorned with heart-shaped leaves, and monopetalous tubular flowers, retained in our gardens for variety, and are also esteemed for their eminent virtues in medicine, and are accounted sovereign in childbirth, as the name imports.

Class

Class and order, *Gynandria Hexandria*.

Characters.] CALIX none. COROLLA is monopetalous, tubular, and irregular, the base is globular, and is extended above into a cylindrical tube spreading at the brim, where the lower part is stretched out like a tongue. STAMINA, no filaments, but six antheræ joined to the under part of the stigma. PISTILLUM, an oblong triangular germen under the corolla, no style, but a roundish six-parted stigma. PERICARPIUM, a large oblong capsule of six cells, filled with depressed seeds.

The species that demand attention are the following.

The first four are hardy, herbaceous, perennial-rooted plants, with annual stalks.

¹ARISTOLOCHIA *Rotunda*.

Round-rooted Trailing Birthwort.] Aristolochia with a roundish root; infirm trailing stalks, two feet long; heart-shaped roundish leaves, sitting close; and blackish-purple solitary flowers.

²ARISTOLOCHIA *Longa*.

Long-rooted Trailing Birthwort.] Aristolochia with a long carrot-shaped root; infirm trailing stalks, eighteen inches long; heart-shaped blunt leaves, having foot-stalks; and purplish solitary flowers.

³ARISTOLOCHIA *Serpentaria*.

Virginia Snake-root.] Aristolochia with infirm, flexible, procumbent stalks, a foot and half long; heart shaped, oblong, plane leaves; and recurved, reddish, solitary flowers.

⁴ARISTOLOCHIA *Clematidis*.

Upright Heart-leaved Birthwort.] Aristolochia with very creeping roots; erect firm stalks, eighteen inches high; heart-shaped leaves, having long foot-stalks; and pale yellow flowers in clusters.

The three following are perennial-stalked exotics of the green-house.

⁵ARISTOLOCHIA *Sempervivens*.

Ever-green Trailing Birthwort of Crete.] Aristolochia with infirm, angular, trailing stalks, eighteen inches long; heart-formed, oblong, waved leaves; and long, recurved, dark purple, solitary flowers.

⁶ARISTOLOCHIA *Pistolochia*.

Pistolochia, or Small Ramose-stalked Birthwort.] Aristolochia with infirm branching stalks, heart-shaped slightly crenated leaves, having foot-stalks, and solitary flowers.

⁷ARISTOLOCHIA *Arborescens*.

Shrubby Upright Virginia Birthwort.] Aristolochia with shrubby erect stalks, two feet

high; heart-formed spear-shaped leaves, and solitary flowers.

The four first species are hardy, have perennial roots, but the stalks are renewed annually in spring; which, of the first, second, and third sorts, if not supported, prostrate themselves upon the ground; but the *Aristolochia Clematidis* stand erect: all of which are adorned with the leaves in alternate order, and flowers proceeding from the sides of the stalks at the angles of the leaves, in June and July, succeeded by ripe seed in autumn.

For purposes in gardens, these four sorts are considered chiefly as plants of variety, or for observation, for as flowering plants they cut no great figure.

As medical plants they are possessed of eminent virtues, being very salutary in many disorders, particularly the roots of the *Aristolochia Rotunda* and *Aristolochia Longa*, which are also remarkable for their drawing properties, insomuch that a poultice of them will extract thorns or splinters from the flesh in any part of the body; and the root of the *Serpentaria* or Snake-root is a cure for the bite of the rattle-snake of America, and all other noxious serpents and venomous animals: these, as well as the others, are efficacious in many other cases. They are imported from abroad to supply the shops, for they are not cultivated here in sufficient quantity for general use, though from seed a few plants may be easily obtained in our gardens.

The Ever-green *Aristolochia*, the *Pistolochia*, and Shrubby Virginia Birthwort, are small exotic perennials of the green-house, durable in root and stalks; the two former being of very infirm and flexible growth, require support; but the stalks of the other, being more shrubby and firm, support themselves erect; all of which produce flowers singly from the angles of the leaves in summer, but rarely any seed in England.

The flower of all the sorts is formed of a single hollow, tubular, irregular petal. See the *Characters*.

Propagation.

The propagation of the three first sorts is by seed sown in autumn, soon after they are ripe, i. e. in September or October, in pots of light earth, which must be placed in a garden-frame to have occasional protection from frost, and in spring the plants will appear; but if the pots are plunged in a moderate hot-bed in March, it will forward them exceedingly, observing to inure them by degrees to the

the full air, giving water during summer, and shelter of a frame in winter, and next spring transplant them, some into a warm border, and some in small pots, to have another winter's occasional shelter, which, in spring after, may also be turned out into the common ground.

The *Aristolochia Clematitis* multiplies exceedingly by its creeping roots, by which it may be encreased at almost any season.

The green-house kinds may be propagated by seeds procured from abroad, and sown in pots of light earth, and plunged in a hot-bed in March; they may also be encreased by slips of the roots in spring, likewise by cuttings, particularly the Shrubby Birthwort; all of which, after being raised in spring and summer, must be potted in autumn, and housed every winter.

ARMA, Arms, Armature, or Offensive Weapon, or Armour of Plants, intended by nature, say naturalists, to keep off naked animals that would approach to hurt them.

There are different species of Armour with which plants are furnished, and are by botanists called, *Aculeus*, prickles, such as those of the rose and raspberry, &c. *Spina*, spine, or thorns, as the hawthorn, buckthorn, false acacia, &c. *Furcæ*, forks, species of prickles, consisting of two or three prongs, as berberry, fig, marigold, &c. *Stimula*, stings, as nettle, &c. See ACULEUS, SPINA, FURCÆ, and STIMULA.

AROMATICÆ Planta. Aromatic Plants are odoriferous, or of a strong, fragrant, agreeable smell and taste, generally warm and cordial; they are chiefly herbaceous, and their virtue resides in the leaves.

Several Aromatics are in great esteem, both for kitchen and medical purposes.

The principal sorts are,

Summer Savory—Winter Savory—Hyssop—Thyme—Sweet, or Knotted Annual Marjoram—Winter, or Perennial Pot Marjoram—Red or Common Sage—Green Sage—Sage of Virtue—Baum—Spear-mint—Peppermint—Pennyroyal—Clary—Lavender—and Rosemary.

All these Aromatics are so useful in the economy of domestic affairs, that they should have places in every kitchen-garden, and their culture is remarkably easy. See their respective genera.

To the above may be added, Basil, Chervil, Coriander, Dill, Fennel, and Tansey.

For other Aromatics, see MEDICAL

PLANTS, POT-HERBS, and VERTICILLATÆ.

ARTEMISIA, Mugwort, comprehending also the species of *Abinthium*, or Wormwood, and *Abrotanum*, the Southernwood.

This genus is very comprehensive, and retains both herbaceous perennials and shrubby plants of the common ground and greenhouse, for medical use and variety in gardens, adorned principally with finely divided leaves, and small compound flowers, of no beauty, in spikes or clusters.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] Compound flowers. CALIX, the general cup roundish and scaly. COROLLA, many hermaphrodite florets compose the middle, and females the border. STAMINA, in each hermaphrodite floret five filaments. PISTILLUM, a germen and style in the florets of both sorts, and bifid stigma. PERICARPIMUM none, a single naked seed succeed each germen.

There are upwards of twenty species, those cultivated for use and ornament are,

¹ARTEMISIA *Vulgaris*,

The Common Mugwort.] Artemisia with pinnatifid, many-parted, plain leaves, downy underneath, and erect firm stalks rising among the leaves, two feet high, each terminated by a long simple spike of small purplish flowers; the radius composed of five florets.

Varieties of this.] Common Plain-leaved Mugwort.—Silver Striped-leaved Common Mugwort.—Gold-striped Mugwort.

²ARTEMISIA *Abinthium*.

Abinthium, or the Common Wormwood.] Artemisia with compound, many-parted, finely divided, whitish leaves; shrubby stalks growing two feet high, closely adorned with leaves, and globular heads of flowers, hanging from the sides of the stalks.

³ARTEMISIA *Pontica*.

Pontic, or Roman Wormwood.] Artemisia with multi-parted, very finely divided leaves, hoary underneath, herbaceous stalks, growing a foot and half long, covered with leaves, and globular heads of yellow flowers, nodding from the sides of the stalks.

⁴ARTEMISIA *Maritima*.

Sea Wormwood.] Artemisia with multi-parted, divided, very downy leaves, shrubby stalks, two feet high, adorned with leaves, and drooping alternate spikes of flowers from the sides of the branches.

⁵ARTEMISIA *Arborescens*,

Tree

Tree Wormwood.] *Artemisia* with an erect, woody, branching stem, grows six feet high; leaves composed of multifid, linear, very hoary, whitish segments; and flowers collected into roundish heads at the ends of the branches.

⁶*ARTEMISIA Abrotanum.*

Abrotanum, or Common Southernwood.] *Artemisia* with shrubby, erect, very branchy stalks, three feet high; fine branchy, bristly, odoriferous leaves, and all the stalks and branches terminated by long spikes of flowers in autumn.

⁷*ARTEMISIA Dracunculus.*

Tarragon.] *Artemisia* with spear-shaped, entire, smooth leaves, and annual shoots.

The flowers of all these species are compound (see the *Characters*), very numerous, though small, and of no beauty.

The *Artemisia Vulgaris* and Common Wormwood are wild inhabitants of uncultivated places, by road sides, bye lanes, banks, and under walls and hedges about country villages; but being efficacious in medicine, are often cultivated in gardens, where they are also sometimes admitted as plants of variety or observation, particularly the variegated Mugworts.

The Roman Wormwood is an exotic of Hungary and Thrace, but is retained in our gardens for variety and uses in medicine.

The Sea Wormwood inhabits the sea-shores of England, and is sometimes admitted in gardens for variety, and as a medical plant.

The above four species flower in June, July, and August, and ripen abundance of seed.

They may be raised abundantly from seed, in almost any situation or soil; and by slips, cuttings, and by parting their roots in autumn or spring.

The Tree Wormwood is an exotic of Italy; it is a hoary ever-green, and considered here principally as a green-house plant, although it will often succeed in the full ground, and by its hoary whitish leaves make a pretty appearance any where. It is propagated by cuttings in a shady border, in April, May, and June; and in autumn some should be potted for shelter in winter, and some may stand to take their chance in the full ground.

The Southernwood is one of our smallest hardy deciduous shrubs, will grow any where, and affords variety in common borders and the fronts of shrubbery clumps.

This little shrub is in great repute about London, and the gardeners about that city

raise vast quantities of them annually, training them about a foot high, with roundish bushy heads, for which they find a ready sale in Covent-garden and Newgate markets; the inhabitants buying them to place in their court-yards, balconies, and windows, in assemblage with other hardy plants that bear the smock.

It is propagated with facility by slips and cuttings of its branches, in a shady border in April; and as many small stems rise from the root, these may be slipped or divided into as many parts as are furnished with the least fibre, and plant them in an open bed in rows nine inches distance, they will form handsome plants after one summer's growth.

The Tarragon, being warm and fragrant, is used as a salad herb; it is perennial, and propagated by its creeping roots, or cuttings of its young shoots in April and May.

ARUM, Wake-Robin, or Cuckow-Pint.

The plants are herbaceous perennials of the common borders and stove, mostly acaulis, i. e. no stalk, but rise with large leaves directly from the root; though some are caulescent, and between the leaves rise a large spadiceous, apetalous, club-shaped flower, of singular structure.

Class and order, *Gynandria Polyandria.*

Characters.] *CALIX*, is a large monophyllous spathe, compressed in the middle, and coloured within. *COROLLA*, no petals, but a large simple, club-shaped, coloured spadix, upon which are placed the germina. *STAMINA*, no filaments, but numerous four-squared antheræ sitting close to the spadix, with a double row of hair-like nectaria between them. *PISTILLUM*, numerous oval germina surround the spadix, no styles, but many bearded stigma. *PERICARPIUM*, many globular berries of one cell, and many roundish seeds.

There are twenty or thirty species, one of which grows naturally in England; all the others are exotics of many different parts of the world, several of which are retained in our gardens: these are,

¹*ARUM Maculatum.*

Common Spotted Arum.] *Arum* without stalk, halbert-shaped entire leaves from the root, and among them rises a short foot-stalk, crowned by a large club-shaped spadix.

Varieties of this.] Common *Arum* with dark spotted leaves—with white spotted leaves—with white and black spotted leaves—with entirely green leaves.

²*ARUM*

²ARUM *Italicum*.

Italian White-veined-leaved Arum.] Arum without stalk; large, halbert-shaped, white-veined leaves, running out to a sharp point, rise from the root a foot and half high, on long foot-stalks, and a large erect whitish spatha rises between the leaves, near a foot in height.

³ARUM *Arifarum*.

Arifarum, or Broad-leaved Friar's Cowl.] Arum without stalk; heart-shaped oblong leaves from the root, and between them is the flower, growing close to the ground, having a bifid spatha and incurved spadix.

⁴ARUM *Dracunculus*.

Dracunculus, or Common Spotted Dragon.] Arum with an erect thick stalk, a yard high, finely spotted like a snake's belly, dividing at top into palmated leaves, having spear-shaped, equal, entire lobes, and between them proceed a long erect purple spatha, protruding a large erect, club-shaped, purple pistil, or spadix, shorter than the spatha.

⁵ARUM *Colocasia*.

Colocasia, or Egyptian Arum.] Arum without stalk; large target-shaped ovate leaves from the root, two-parted at the base, and with sinuated waved borders.

⁶ARUM *Trilobatum*.

Trilobate, or Three-lobed Indian Arum.] Arum without stalk; leaves from the root, composed of three arrow-pointed lobes, and between them rise the flower on a short foot-stalk, having a long spatha and scarlet spadix.

⁷ARUM *Arborescens*.

Tree American Arum, or Dumb Cane.] Arum with an erect jointed stalk, six feet high, arrow-shaped leaves in clusters at top, and the flowers rise between the leaves in long green spathæ, sitting close to the stem.

All these plants are herbaceous, perennial in root, but mostly annual in leaf and stalk, which rise in spring, flower in April, May, and June, ripen seeds soon after, and die to the ground in autumn.

The roots are mostly thick, fleshy, and multiply considerably.

The leaves are large and broad, and some are very beautiful.

The flower-stalks of all the sorts support a single spatha or scabbard, protruding the flowers, having no petals, but a large red or purple spadix or pistillum, elevated like a column, which is succeeded by a cluster of berries, containing the seeds; but very few of these plants ripen seed in this country.

The *Arum Maculatum* is a resident of our woods and banks under hedges, but the plants are admitted for variety in pleasure grounds, in assemblage with the other hardy sorts; but the spotted kinds of them have most merit, and form an agreeable diversity.

The second and third sorts are exotics, though of hardy growth, and have been long entertained in curious gardens for their singular appearance.

The *Arum Dracunculus* is a hardy plant, of so singular and august appearance, that it deserves a place in every collection of herbaceous perennials, although the strange singularity of its maculated snake-like stem is disagreeable to some, and its flower emits a disagreeable odour.

All the above four species succeed in any of the common borders.

The fifth, sixth, and seventh sorts are exotics of hot climates, and are preserved here in stoves as plants of curiosity.

Propagation.

The propagation of all the sorts is easily accomplished, and mostly by parting the roots.

The first six sorts encrease greatly by their roots, and the off-sets may be separated, or the whole root divided in autumn, after they have flowered, or early in spring; those of the hardy kinds are to be planted in the borders, and the tender sorts in pots, and retained in the stove.

Those of the hardy sorts that ripen seeds may also be raised by sowing them in pots in autumn, and if those are plunged in a hot-bed in March, just to bring up the plants, it will forward them greatly.

The Tree Arum is propagated by cuttings of its stalk, three joints in length, which, after having lain four or five weeks, till the cut part is healed, plant them separately in pots, and plunge them in the stove.

ARUNDO, the Reed.

The plants are mostly herbaceous perennials, some of which rise with herbaceous stalks, from three to twelve feet high; others have tree-like stems, advancing with amazing rapidity of growth to thirty or forty feet in height.

Class and order, *Triandria Digynia*.

Characters.] CALIX is a glume, or husky scale of two valves. COROLLA, two acuminate husky valves, downy at the base. STAMINA, three filaments, and horned antheræ. PISTILLUM, a germen, two reflexed styles, and

and simple stigma. PERICARPIUM none, and the seed is single.

The plants are of the grass tribe, and produce their flowers in spikes, which have no beauty.

The species of note are,

¹ARUNDO *Phragmites*.

The Common Marsh Reed.] Arundo with slender erect stalks, six or eight feet high, terminated by loose panicles of flowers, growing five in each cup.

²ARUNDO *Donax*.

Donax, or Portugal Reed.] Arundo with large erect stems, ten or twelve feet high, terminated by diffuse panicles of flowers, growing three in each cup.

³ARUNDO *Versicolor*.

Variegated Indian Reed.] Arundo with erect firm stalks, four or five feet high, adorned with variegated leaves, and terminated by diffuse panicles of flowers.

⁴ARUNDO *Bamboo*.

Bambu-Cane, or Great Indian Reed] Arundo with a very large erect stem, growing thirty or forty feet high, adorned with very large, long, and pointed leaves, and sessile spikes, having many flowers in a cup.

The first three sorts are hardy, but the Bambu-Cane cannot live in our climate, unless it is indulged with a place in the hot-house.

The *Arundo Phragmites* or Common Reed is an inhabitant of our river sides, and standing waters, all over the kingdom, so is rarely admitted in gardens. This species growing in great abundance in marshy situations, and the roots sending up an annual crop of stalks, are, in many places, constantly cut in autumn, and tyed in bundles for sale, being useful for various purposes, such as thatching houses, &c. and among gardeners, they are employed in forming shelters, called reed-hedges, being cheap, and quickly made shelter for young and tender plants in winter, both in nurseries and large kitchen grounds, see REED-HEDGES, and for which, and many other uses, great quantities are brought in barges up and down the river Thames to London, where they may be purchased in the ware-houses contiguous to the river.

The Portugal or Spanish Reed is retained in many of our gardens for its singular lofty growth; it prospers in any common soil of a garden: the stalks rise annually in spring, frequently from three to twelve from the same root; they are large and jointed, and

attain ten or twelve feet stature in three or four months, adorned with large long leaves at the joints, but it rarely flowers here.

The Variegated Indian Reed, is, in its general habit, the same as the Portugal kind, only the whole plant is of much smaller growth.

Both these sorts are easily propagated by dividing their roots in February or March, before they begin to shoot forth new stalks, and the slips will shoot the same season, though not with vigour until the second or third year.

The stalks may be cut down every autumn, and used as walking-sticks, &c.

The *Arundo Bamboea* is a native of both Indies, and is retained here in our stoves as a plant of singularity; in its native soil it grows forty feet high, and attains considerable substance, and even in our hot-houses, where there is room, they often grow at the astonishing rate of twenty feet in six weeks; the stems of these Canes are used here for walking-sticks, fishing-rods, &c. but in India the large ones are employed for various purposes, and the leaves being very large and long, are skewered together to form mats for package, so arrive here in tea-chests, &c. and we often see them in the streets thrown out of the grocer's shops.

The propagation of this Cane is easily accomplished by taking off slips from the roots in February or March, planting them in large pots, which plunge in the bark-bed in the hot-house, where they are always to remain.

As they grow naturally in marshy places, they must be plentifully watered.

ASARUM, *Asarabacca*.

The plants are low herbaceous perennials, adorned with simple leaves and apetalous flowers, which rise but very little from the ground, and are retained in gardens for variety, and some as medical herbs.

Class and order, *Dodecandria Monogynia*.

Characters.] CALIX is monophyllous, bell-shaped, coloured, three-parted, and reflexed at the brim. COROLLA none. STAMINA, twelve filaments, and oblong antheræ. PISTILLUM, a germen, cylindric style, and six-parted stigma. PERICARPIUM, a leathery capsule of six cells, having oval seeds.

The species are,

¹ASARUM *Europæum*.

European, or Common English Asarabacca.] Asarum with kidney-shaped, bluntly two-pointed, shining leaves, rising from the root on

on short foot-stalks, and among them purple flowers, close to the ground.

²ASARUM *Canadense*.

Canada Asarabacca.] Asarum with large kidney-shaped, pointed, hairy leaves from the root, on long foot-stalks, and among them greenish flowers, sitting close to the ground.

³ASARUM *Virginicum*.

Virginian veined-leaved Asarabacca.] Asarum with heart-shaped, rounded, smooth, veined, and spotted leaves from the root, on very long foot-stalks, and dark purple flowers elevated among the leaves.

They are all hardy, herbaceous, fibrous-rooted perennials, whose leaves and flowers rise directly from the root, and grow near the ground; the flowers of the first and second sorts having very short foot-stalks, are insufficient to elevate them above the leaves, but those of the third being much longer, the flowers are more conspicuous.

They flower in May, and ripen seeds in August.

The flowers are universally apetalous, so consist only of the bell-shaped coloured calix. See the *Characters*.

Considered as plants of ornament, they make no great figure; but as plants of singularity in their flowers, mode of flowering, &c. they merit places in the front of borders, and other compartments, among plants of lowest growth.

As medicinal plants, the Common Asarum is the sort prescribed, and is efficacious in many disorders.

The propagation of all these three species is by parting their roots in autumn or spring.

ASCLEPIAS, Swallow-Wort, comprehending also several sorts of Dog's-Bane, removed by Linnæus from the genus *Apocynum*.

This genus furnishes a choice collection of tall flowery perennials, both herbaceous and shrubby, of the full ground, green-house, and stove, obtaining from two to seven feet stature, ornamented with simple leaves and monopetalous flowers, in clusters.

Class and order, *Pentandria Digynia*.

Characters.] CALIX is monophyllous, and five-parted at the brim. COROLLA, a single petal cut into five oval segments, and five horned nectaria encompass the fructification. STAMINA, five scarcely visible filaments, and five antheræ situated between the nectaria. PISTILLUM, two oval germina, two short styles, and single stigmas. PERICARPIUM, two large oblong swelling pods, having compressed seeds.

The following ten species are those chiefly known in the English gardens; the first eight of which are herbaceous and hardy.

¹ASCLEPIAS *Vincetoxicum*.

Vincetoxicum, or Common White Swallow-Wort.] Asclepias with erect jointed stalks, growing two feet high; oval leaves by pairs, bearded at the base; and white flowers in branching clusters near the top of the stalks.

²ASCLEPIAS *Nigra*.

Black-flowered Swallow-Wort.] Asclepias with slender stalks, rising three feet high, twining at top; oval spear-shaped opposite leaves, by pairs, bearded at the base; and black flowers in branchy clusters from the upper part of the stalks.

³ASCLEPIAS *Lutea*.

Yellow Swallow-Wort.] Asclepias with infirm stalks, two feet long, narrow oval acute leaves, and yellowish flowers in simple clusters near the top of the stems.

⁴ASCLEPIAS *Syriaca*.

Syrian Broad-leaved Purple Dog's-Bane.] Asclepias with very creeping roots, sending up strong erect simple stems, four feet high, having large oval thick leaves, by pairs, downy underneath, and purplish flowers in nodding clusters near the top of the stems.

⁵ASCLEPIAS *Purpureascens*.

Purplish Carolina Dog's-Bane.] Asclepias with erect stalks growing a yard high, adorned with oval leaves, by pairs, hairy underneath, and the stems terminated by erect umbels of purplish flowers, having declinated nectaria.

⁶ASCLEPIAS *Verticillata*.

Whorled-leaved Maryland Asclepias.] Asclepias with erect slender stems, two feet high, narrow revolute leaves placed in whirls round the stalk, and the stalks crowned by umbels of white flowers.

⁷ASCLEPIAS *Decumbens*.

Declinated Orange-coloured Virginia Dog's-Bane.] Asclepias with declinated hairy stalks, a foot and half long, garnished with oval hairy opposite leaves, and the stalks terminated by compact umbels of orange-coloured flowers.

⁸ASCLEPIAS *Tuberosa*.

Tuberous-rooted Erect Orange-coloured American Dog's-Bane.] Asclepias with a large tuberous root, erect divaricating hairy stalks, about two feet high, adorned with spear-shaped hairy alternate leaves, and the stalks surmounted by umbels of orange-coloured flowers.

The following is a green-house plant.

⁹ *ASCLEPIAS Fruticosa*.

Shrubby Asclepias.] *Asclepias* with shrubby erect very branchy stems, growing six or eight feet high, all the branches closely garnished with long spear-shaped smooth leaves, and white flowers in single loose umbels, on long foot-stalks, from the sides of the branches.

The following is a stove plant.

¹⁰ *ASCLEPIAS Curassavica*.

American Scarlet Asclepias.] *Asclepias* with erect single stems, rising five or six feet high, spear-shaped smooth opposite leaves, having foot-stalks, and flowers from the upper parts of the branches, in erect single umbels, having scarlet petals, and saffron-coloured nectaria.

All these plants are exotics principally of America, and are retained here in most of our curious gardens as plants of ornament.

The first eight species are hardy herbaceous perennials, with fleshy fibrous abiding roots; but the stalks are annual, they rising in spring, attain their full growth in three or four months; flower in June, July, and August; perfect seeds in September, and soon after the whole dies down to the ground.

Ripe seed however is only to be expected here principally from the first four sorts, and sometimes from the *Asclepias Decumbens* and *Tuberosa*.

The above eight hardy species are elegant furniture for the pleasure ground; they will succeed in the common borders, and may be employed in the embellishment of the shrubbery clumps, disposing them towards the front, and their general culture is the same as other hardy herbaceous perennials. See HERBACEOUS PLANTS.

Observe however that as the two Orange Dog's-Banes are sometimes affected by severe frost, it is eligible to allow them a warm dry situation, also to pot some of each for shelter in winter.

The *Asclepias Fruticosa*, and the American Scarlet *Asclepias* are tender exotics; the former that of the green house, and the latter of the stove. These are elegant plants, and remarkably beautiful when in flower, which is generally from about Midsummer until October, and they frequently afford us ripe seed for their propagation. They must always be cultivated in pots, and the former sort placed in a green-house in winter, and the other must be retained always in the stove; and as they are milky plants, should be very sparingly watered in winter.

The flowers of all these ten species are produced in umbellated clusters; each separate flower is rather small, and formed of one leaf or petal, and five horned nectaria. See the *Characters*.

Propagation of all the Species.

The first six species are propagated plentifully by dividing the roots in autumn, when the stalks decay; or in spring, before new ones begin to shoot forth.

They may also be raised from seed in a bed of common earth, in March and April.

The seventh and eighth sorts are propagated principally by seeds in pots of light earth in spring, plunging them in a hot-bed, and when the plants appear, inure them by degrees to the full air; then prick them upon a sheltered border, six inches apart, giving occasional shade and water; also shelter from frost in winter by covering the bed with litter or mats, and in March transplant them where they are to remain.

The Shrub *Asclepias* is propagated by seed and by cuttings. By seed, sow them in pots of light compost in March or April, and plunge them in a hot-bed, and when the plants are three inches high, prick them in separate small pots, giving shade and water. By cuttings, plant them in pots any time from March till Midsummer; move them to the shade, and give water, and in autumn they will be rooted, when they are to be separately potted, moving the whole to the green-house in October.

The tenth sort is also raised from seed in a hot-bed; when the plants are three inches high, prick them in separate pots, and plunge them directly in the hot-house.

ASHES, for Manure to Land.

Ashes, as manure or dressing to land, may be applied to considerable advantage in cold, heavy, inactive soils.

There are several sorts of Ashes used in the improvement of land, such as Coal-ashes, Wood-ashes, Turf-ashes, Fern-ashes, Furze, and Heath-ashes.—Ashes of all sorts of burnt vegetables, such as burnt weeds, sedge, straw, stubble, bean-haulms, &c. also Pot-ashes, and Soap-ashes from the soap-boilers.

All these sorts of Ashes are of particular utility in the improvement of cold, wet, stubborn land, to warm, open, and loosen the mould, and augment its vegetable and prolific quality.

Coal-ashes are particularly efficacious in the meliorating and fertilizing all cold, stiff, or

or clayey soils, in gardens or fields; and in grass ground of the above quality; they have a great effect in preventing the rankness and coarseness of the grass peculiar to such soils, by making it come finer, and rendering it more sweet for cattle to feed on.

ASH-KEYS, the fruit, or seed-vessel, of the Ash-tree. See *FRAXINUS*.

ASPARAGUS, *Asparagus*, falsely called Asparagras.

The common *Asparagus* is one of our choicest esculents of the spring and beginning of summer, and highly merits culture in every garden.

But besides the common Garden *Asparagus*, the botanists present us with nine or ten more species in the same genera, under the title of *Asparagus*, which are principally tender shrubby exotics of the green-house and stove; several of which are retained in our gardens, which we shall take notice of after the culture of the esculent kind.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, six petals, forming a tube below, and spread at top. STAMINA, six short filaments, and roundish antheræ. PISTILLUM, a trigonous germen, very short style, and prominent stigma. PERICARPIUM, a globose berry, of three cells, each having two roundish seeds.

We shall first of all proceed in the culture of the common *Asparagus*, and the following is the species.

ASPARAGUS Officinalis.

The *Officinal*, or *Common Asparagus*.] *Asparagus*, with an erect herbaceous stalk, three or four feet high, and very fine bristly leaves.

This is a perennial fibrous-rooted plant, the roots being of many years duration, but the tops or stalks are annual, and the plants being raised from seed, they, after having acquired a period of three years growth, produce proper sized *Asparagus*, and of which, the same roots furnish an annual supply for many years, continuing to rise in perfection for six or eight weeks each summer; then the shoots run up to stalks, flower, and perfect seeds in autumn.

It is the young shoots, or stalks, of the plant that are used, which, when from about one, to four or five inches long above the surface of the ground, are in the greatest perfection.

The natural season of these plants for use is, from about the beginning of May, until the middle or latter end of June. For about the fourth week in April, or first in May, the roots begin to send up shoots or buds, and as

often as these are gathered, new ones continue rising in succession from the same roots; but in order to preserve the roots in vigour, it is adviseable to leave off cutting the buds about the third or fourth week in June. The common rule is, to continue cutting about six or seven weeks, then permit the whole to run up to stalk.

But besides the crop of natural *Asparagus* in summer, it may also be obtained in perfection in winter, and early in spring, by the aid of hot-beds. See the *Method of forcing Asparagus*.

Propagation of the Plants.

The propagation of *Asparagus* is by seed only, which is sold cheap enough at all the seed shops. It is to be sown in February, or beginning of March, in a four-feet wide bed of rich earth, broad-cast on the surface, and directly tread it in, and rake the ground.

In six weeks, or thereabouts, the plants will appear. Keep them clean from weeds all the summer, and in winter spread a little litter on the ground, to defend the crowns of the roots from frost, and in spring following they will be fit to be transplanted, where they are finally to remain, as hereafter directed, which, in two or three years after, will produce *Asparagus* fit to gather; for, observe, *Asparagus* is always three years, at least, from the time of sowing the seed, till the plants obtain strength enough to produce shoots of due size for the table; that is, one year in the seed bed, and two after being transplanted; but the same plantation will continue producing good *Asparagus* ten or twelve years, nay, will even endure fifteen or twenty years; but at that age, the shoots will be small, and the whole annual produce inconsiderable; a new plantation should therefore be made once every eight, ten, or twelve years, as you shall judge necessary.

If you are desirous to have a new plantation of *Asparagus*, fit for use, as soon as possible, you may gain a year, by purchasing ready raised year-old plants of the nursery-men, or kitchen-gardeners, at a shilling or eighteen-pence per hundred.

But this is only meant for private use, as those who raise great quantities for sale, would find it very expensive to purchase roots for large plantations, some of which, in the neighbourhood of London, are very extensive, particularly about Deptford, where some of the gardeners have twenty acres of ground employed in *Asparagus*.

Method

Method of Planting.

The time of year to make a plantation of these plants, is any time in March, in common light ground, and at latest, the first or second week in April; but in cold very moist soils, from about the twentieth of March to the 15th of April, is the proper time to plant them in such land.

With regard to soil and situation, the plants succeed tolerably in any common pliable soil of the kitchen-garden; but it is, however, eligible to allow them a spot of the very best and richest moderately light ground, in one of the open quarters, exposed to the free air and full sun; for this is of much importance. Dung must be added, six or eight inches thick at least, but if ten or twelve the better. The ground is then to be trenched one or two spades deep, as you shall see necessary, burying the dung regularly in each trench, observing, if you trench but one spade deep, bury the dung in the bottom, but if you dig two spades, bury it betwixt the first and second spit, about ten or twelve inches below the surface; and if the trenching is performed in winter, or any considerable time before the planting season, it is proper to throw the ground in ridges, so level it down when that time arrives. See **TRENCHING and RIDGING GROUNDS.**

The necessary space of ground to plant for private service, is from about five, to fifteen rod, making the calculation according to the extent of the family.

The proper quantity of plants to a rod, exclusive of the alleys, is about 260.

Always chuse one year old plants, not older, as those of that age will establish themselves sooner, and more effectually than older roots.

The plants, at the time of planting, consist only of roots; they, at the proper time, are to be taken up from the seed-bed with a dung-fork, as entire as possible; and sort out the strongest for planting, which are not to be trimmed, only cutting off such parts as are broken or bruised.

They are to be planted in rows a foot asunder, and formed into beds, each bed to consist of four rows, allowing three foot and half alleys betwixt bed and bed, and are to be planted in drills, or small trenches, in the following manner. Begin at one end of the plat of ground, and stretch a line cross-ways eighteen inches from the end; then with the spade held in an erect position, cut out a narrow trench, close along the outside of the line,

six or eight inches deep, making the side next the line nearly upright. This done, get the roots, and place them against the upright side of the trench, ten or twelve inches distance, with the crowns two inches below the surface, spreading the fibres both ways, and draw a little earth up about each plant as you go on, just to fix them till the row is planted. One row being thus formed, move the line a foot farther, and cast out another trench, the earth of which readily covers the plants of the first; place the roots as before directed, and so on to a third and fourth row, making the earth of each trench cover in the plants of that immediately before it; and when four lines are planted, one bed is formed. Then measure off three feet six inches for an alley, &c. and proceed to plant another bed of the same dimensions; and after that, leaving another three-foot and half alley, plant a third bed, and in this manner proceed until your plantation is completed.

The beds and alleys may either be lined out now, or deferred till the winter dressing, observing, that of the three feet six inches directed for alleys, two feet only are to be allowed for that use, the other foot and half is to be added to the beds, which makes each bed four feet and half wide, i. e. nine inches on each side wider than the two outside rows of plants; but at this time the alleys are only to be trodden out, taking out none of the earth, and so stand in the alleys and lightly rake the beds smooth.

But in making the above plantation, that if you have occasion to make the most of every spot of ground, a thin crop of onions may be sown the first year on the same plat as soon as the Asparagus is planted; so tread in the seed, and rake the beds with a light and even hand.

The Asparagus being planted, their culture is as follow. Their shoots will appear above ground the beginning of May not bigger than straws, so must be permitted to run wholly to stalk. During summer they must be kept clean from weeds, by small-hoeing them three or four times in the course of that season; and if there is a crop of onions, thin them in the usual way, cutting up any that grow immediately about the Asparagus. In October, when the Asparagus stalks decay, cut them down, clear off weeds, and dig the alleys two feet wide, (See *Winter Dressing*) burying the weeds therein, and spread some of the earth over the beds, which is all that is necessary

necessary to be done until March, at which time the beds should be deeply hoed and raked smooth, permitting the shoots to run as in the first summer; and in October, cut down the decayed haulm as before, and land up the beds. In spring following, being the second after planting, slightly fork-dig the beds, (see *Spring Dressing*) and rake them level, and in this spring the shoots will rise of tolerable substance, when you may begin the first gathering. See *Winter Dressing*, *Spring Dressing*, *Manuring the Beds*, and *Gathering the Buds*.

Winter Dressing, or Landing up the Beds.

From about the middle of October, to the latter end of November, is the time to give the Asparagus beds their Winter Dressing.

This dressing consists in cutting down the decayed stalks of the plants annually at the above time, and clearing the beds from weeds, digging the alleys, and spreading some of the earth on the top of the beds, which is called landing up the beds.

It is done in the following manner.

The decayed stalks or haulm are to be cut down with a knife within an inch or two of the ground, then with a sharp hoe cut up all weeds, at the same time drawing them off into the alleys to be buried. This done, proceed to line out the alleys, stretching the line along the edges of the beds about nine inches from each outer row of plants; the stumps of the stalks will be a guide; then with a spade chop the ground along by direction of the line, by which you form each bed four feet and half wide, and the alleys two feet. See the *Method of Planting*. The alleys are then to be dug one spade deep, and a good portion of the earth spread over each bed three or four inches thick; as you proceed in digging, the weeds drawn off the beds are from time to time to be trimmed into the bottom, and buried a due depth, observing to land the beds all a regular thickness, so as to make them about six or eight inches higher than the level of the alleys, forming the edge of each bed full and straight.

The above work of landing the Asparagus beds must be repeated every autumn.

It may by some be thought, that by an annual landing of the beds, they in several years will be considerably raised; but observe, that by the spring forking and raking, together with the repeated hoeings and clearing off weeds in summer, and at the time of landing up in autumn, a considerable part of the earth is annually drawn off again into the alleys.

After performing the winter dressing of these beds, a row or two of cabbage plants may be planted in each alley, as a place of shelter during winter, by which they will be forwarded for early spring coleworts; or a row of mazagan dwarf beans may be planted in October or November, in the warmest side of each alley, for an early crop. The market gardeners also often occupy the beds during winter, by planting a crop of cabbage lettuce hereon for spring service, which being all gathered or transplanted elsewhere by the beginning of April, do not injure the Asparagus.

Of the Spring Dressing the Beds.

The Spring Dressing of Asparagus beds consists in fork-digging the beds annually to a moderate depth, to loosen the soil, that the buds may freely advance and swell to their due size.

The time for performing this work is any time in March, but not to defer it later than the first or second week in April, because many of the buds will then be formed, and in forward seasons, begin to advance in growth.

This work of loosening the beds is performed with a flat three-tined fork.

Observe, however, that in the first spring dressing after planting, it is proper to loosen the surface only with a hoe, two or three inches deep, and so rake the beds smooth.

But in respect to the general spring dressing, it is to be annually performed by fork-digging, to all such beds that have been planted more than one year, which should be slightly dug four or five inches deep with the Asparagus-fork, being careful to loosen all the earth as deep as the surface of the roots, having regard, however, not to wound the crowns of them; and after forking, let all the beds be neatly raked, to break clods, clear off stones, and to form a level and smooth surface, finishing each bed with a gentle rounding.

Of Dunging, or Manuring the Beds.

These beds should be enriched with an augment of good rotten dung once every two years, the benefit of which will be evident in the quantity, as well as the size and quality of the produce.

The time to apply this manure, is at the time of winter dressing, or landing up the beds.

The dung for this purpose should be perfectly well rotted; none better than the dung of old cucumber and melon beds, or any other of

of similar quality, which should be applied when the stalks and weeds are cleared off, the dung is to be spread three inches thick over the surface of each bed, and a double portion in the alleys; the beds are then to be slightly forked to bury the dung; after this dig the alleys in the usual way, and spread a portion of the earth evenly over the beds.

The winter rains will wash the enriching quality of the above manure into the beds, and the roots will reap the benefit thereof in spring.

Of Gathering the Produce.

We formerly observed, that Asparagus, from the time of sowing the seed, till the plants produce buds large enough for use, is commonly three or four years; that is, one in the seed-bed, and two or three after being transplanted; they, however, sometimes, in very rich ground, yield tolerably large buds the second year, but of which I should advise to cut only here and there one of the largest that happen to appear the first week or fortnight; afterwards permit the whole to run to stalk; but in the third year you may perform a more general gathering, and continue it a month or five weeks; and in the fourth year, the general produce will rise in its utmost perfection: you may then, and every succeeding year, gather all the buds arising from every plant during the season of Asparagus.

The proper size of the buds for use is, when they are from about one to four or five inches high above the surface of the earth, while the heads remain compact and plump.

The principal season of cutting them, is from the latter end of April, or beginning of May, according to the forwardness of the season, until the middle or latter end of June.

They might, however, be obtained a month or two longer in the season, by continuing to cut all the buds according as they attain proper size; but this would be a very wrong practice, as the roots would thereby continue sending up a fresh supply, till they in a manner exhausted their vegetable fund, as would be apparent by the inconsiderableness of the future year's crop, and short duration of the plants.

The gatherings therefore should be terminated about, or soon after the 20th of June, especially, as by that time there will be plenty of young peas, to substitute as a dish at table in lieu of the Asparagus.

If late Asparagus is however wanted, some beds should be set apart for that purpose, exclusive of the main crops.

For the purpose of cutting the Asparagus for use, it is necessary to be furnished with a long strait narrow-pointed knife, the blade six or eight inches long, teathed on the edge like a saw; and in cutting the Asparagus, slip the knife down close to each separate bud, and cut them off slanting three or four inches within the ground, being careful not to injure any of the younger buds rising in succession, there being generally several from the same root, advancing in different stages of growth.

The gardeners who supply the London markets with Asparagus, sort it into three sizes, a large, middling, and small sort; the former they call ware, the next middlings, and the latter sprew; they sell it wholesale by the basket, three, four, or five hundred buds in each, according to their size, and those that retail it, bind it in bundles, from one to three hundred in each bundle.

In preparing Asparagus for the table, the cook should slightly scrape each shoot, to divest them of the small scaly parts annexed to their sides, tie them in small bunches, the heads all one way, then cut the white ends even; they are then ready for boiling, which is effected in fifteen minutes.

Forcing or raising early Asparagus.

As many families are anxious to have Asparagus in winter, and early in spring, I shall next proceed to the method for obtaining it also in these seasons.

This is effected by means of planting the roots in substantial hot beds, covered with frames and glasses, as hereafter directed.

This work is by gardeners called forcing Asparagus.

As the practical method of forcing Asparagus has not been digested by former authors on gardening, I propose to handle this article at some length, according to real practice, for the benefit of my brother-gardeners, who have not had the opportunity of seeing the true practical part; and as the London kitchen-gardeners, having great experience, by forcing vast quantities annually, it is generally allowed they excel in the production of winter Asparagus, I shall exhibit the whole culture according to their method.

Previous to this work it must be observed, that when intended to have a constant succession of Asparagus during winter and spring, a new hot-bed must be made, and planted with fresh plants every three or four weeks, for these roots, when forced in hot-beds, do not continue to yield any tolerable produce longer

longer than that period of time, when they will in a manner be quite exhausted, and are not fit for that nor any other purpose afterwards: therefore, for this purpose of forcing, a fresh quantity of plants must be in readiness for every new hot bed: these are raised in the natural ground to a proper age; they must be three or four years old; that is, the plants are raised from seed, as directed for the natural-ground Asparagus, and when they are one year old, transplant them in beds of rich earth, as directed also for the natural plantation, in rows a foot asunder, but need not be more than nine inches distance in each row, forming them in beds of six rows in each, with only two feet alleys, just to go in to clean off weeds, &c. for the beds need not be landed up in winter, as in the natural Asparagus; and when the plants have had two summers growth, they, in good ground, will be fit for forcing, though they will be in greater perfection, if permitted to stand three years. During the time they remain in the natural ground, no buds should be gathered, at least very few, but permit the whole to run to stalk each summer.

It must next be observed, that when intended to force Asparagus annually, some seed must be sown every spring, and a due quantity of plants transplanted as before directed, so as to have three different pieces of ground always employed at the same time with Asparagus plants for the above purpose; that is, one piece with seedlings in the seed-bed, the other two with transplanted plants, one to be a year's growth before the other; by which practice, after the three first years, you will obtain an annual succession of plants fit for a forcing.

But as some persons may be impatient to wait the raising the plants, or may be anxious to have a supply till their own are ready, in which cases, they may be furnished with them at most of the kitchen-gardeners in the neighbourhood of great towns, particularly that of London, where they commonly sell them by measurement of the ground they grow upon, generally from six to ten shillings per rod, according to the age, size of the plants, and fullness of the crop.

The necessary quantity of plants for hot-beds is considerable, since about as many as grow upon three rods of ground is requisite for a bed intended for a common three-light garden-frame. The common allowance of the London gardeners is about one rod to a light; for the plants are to be placed as close as they

can possibly stand to one another, to the amount of five, six, or seven hundred, or more, according to their size, in a three-light box, otherwise a bed would not afford a sufficient supply, adequate to the expence and trouble necessary in the culture of these plants in hot-beds; for, from a bed of the above dimensions, we commonly expect about three hundred large buds, or ware, besides sprew, weekly, and in the whole about eight or nine hundred good Asparagus, and near as many small ones in three weeks, in which period of time the roots will have exhausted their strength, and can produce very little more.

Therefore, in raising or procuring plants for the above purpose, the quantity must be proportioned to the number of lights you intend working, and the succession of Asparagus required, which may be readily calculated according to the foregoing observations.

The season to begin the above work of forcing, is according to the time the Asparagus is required for use; as, for instance, if you would have Asparagus at Christmas, it is proper to make the hot-bed in the first or second week in November, and so on in proportion to any other time of the winter or spring it is desired to have Asparagus fit to gather. The rule is this: if a constant succession is required from about Christmas till the time of the natural Asparagus come in, a new hot-bed should be made every three weeks or a month, as already observed, from the beginning of November until that of March; but some of the London gardeners begin about the latter end of September, in order to obtain Asparagus against Lord Mayor's day, which happens the second week in November.

Previous to making and planting the hot-bed, observe also the following particulars.

As to the hot-beds for this purpose, the proper materials are, a sufficient quantity of horse or stable dung, fresh, and full of heat, wherewith to make the hot-bed for one or more three-light frames, two feet and half, or a yard high; also some to line it when the heat declines, a quantity of good kitchen-garden earth, and one or more three-light garden-frames to place over the bed, and some large garden-mats, to cover occasionally on nights and bad weather.

The dung for making these beds is to be previously prepared, as directed under the article HOT-BEDS.

The situation for the hot-beds should be where the ground is light, rich, and dry, for the

the convenience of having plenty of good light earth at hand for earthing the bed, banking up the outside plants, and moulding them at top, &c.

The exposure should be open to the full sun, and defended from the northerly winds.

It is eligible to make the bed in a trench four or five feet wide and one deep, so that the earth dug out in forming the cavity, serves in part to earth the bed and plants as above.

As to the general dimensions of the bed; it is made a foot wider and longer than the frames intended to cover it, that is, six inches on each side and end, whereon to bank up earth against the outside roots, &c. and must be two feet and half, or a yard high, earthed at top six inches thick for the reception of the plants, which are placed entirely upon the top of the earth before the frame is put on, keeping them within the compass thereof, upright, and as close as they can stand, as hereafter directed; and as there being a clear space of six inches on each outside and end, as above hinted, is to receive a wall or bank of earth against the outside roots, and for the support of the frame, the latter of which, on account of the first violent heat, is not put on till two or three weeks after planting the roots; these, as soon as planted and banked up on the outsides, are earthed an inch deep, which is increased to five or six, when the buds appear through the first earthing, at which time, as the heat of the bed will be moderate, the frame and glasses are placed thereon. See the *General Culture*.

Method of making the Bed, planting the Roots, and Culture.

In the situation and exposure above described, mark out a trench for the hot-bed, twelve or fourteen inches wider than the intended frames, and of a proportionable length, whether for one, two, or more, and dig out the cavity one spade deep, then wheel in the dung, and with which form the bed the full width and length of the trench, observing, if only for a single three-light frame, make the bed a yard high, but if for two or more such frames in one range, two feet and half depth of dung is sufficient, working the whole upright and firm in the usual way. See *HOT-BEDS*.

When the bed is thus formed, let it be directly earthed at top for the reception of the plants, with finely broken earth six inches thick, to the full width and length of the bed, and rake the surface level and smooth; this done, im-

mediately proceed to place the roots, for no time must be lost in Asparagus hot-beds in waiting for the temperature of the heat. Previous to planting the roots, mark out on the surface of the bed the exact width and length of the frames, so as to have a clear space on each outside of six inches width, to receive the banking of earth against the outside roots, &c. as before-mentioned; then begin at one end, and raise a small ridge of earth crossways upon the surface, about six inches high, against which to lay the first row of roots; then having the roots, which are not to be trimmed, lay the first course close against the above ridge, and intirely upon the surface of the bed, with the crowns upright, and as close to one another as you can possibly place them, and when one course or row is thus placed, lay another against these in the same manner, and so proceed, laying them one against another as close together every way as you can possibly crowd them from one end of the bed to the other, without laying any earth between or about the fibres, for these will soon strike down into the earth of the bed, being careful to place all the crowns of such an equal height, that the whole may form, as it were, a level surface, keeping the whole rather within the measure of the frame, for they will unavoidably swell out a little on each side, observing, if more frames than one are intended for the same bed, then at the termination of the length of each frame, raise a cross ridge of earth, as at first, about six inches in height; so proceed laying the plants, as before, and when all the roots are thus placed the whole length of the bed, directly bank up some earth on each side and end, as above hinted, against the outside roots, raising it an inch higher than the crowns of them, then cover the crowns all over evenly with finely-broken light earth an inch deep, which finishes the work for the present until the buds appear, which see, for the roots must not till then be earthed deeper, nor the frame placed upon the bed, till the violent heat has subsided, because it would confine the burning steam, and occasion the bed to heat too vehemently, to the destruction of the plants.

In making the above beds, many of the London gardeners, to save dung, instead of making the beds a foot wider than the frames, as above directed, make them only the exact width of the frame; so to secure the outside roots, and for the support of the frame, raise a bank of earth quite from the ground,

ground, six inches broad, drawing it in gradually to the top, banking it close against the sides of the bed, and that of the outside roots, raising it an inch higher than the crowns of them, so earthing them all over the top an inch deep, as before observed; which method of banking quite from the ground, is very effectual in preserving the temperature of the bed, by defending the dung from driving rains, snow, and piercing winds.

As soon as the beds are made and planted in either of the above methods, then, in order to judge of the temperature of the heat, it is proper to thrust some sharp-pointed sticks, two feet long, down betwixt the roots into the dung of the bed, and by drawing these up daily, and feeling the lower end, you will be able to judge of the degree of heat, whether too violent or weak, which is to be regulated accordingly, as hereafter directed.

The beds being made and planted, the roots will soon after send forth fresh fibres into the earth, and even, in time, into the very dung, and the buds of the Asparagus will begin to appear in about three weeks; but till that period, as the heat will be very strong, the bed is to remain unframed and uncovered, except being occasionally defended at top with long litter or garden mats, from violent rains, snow, and severe frosty weather, observing, however, that until the buds appear, moderate rains, frosts, &c. can do no damage; therefore use only slight and occasional covering, as above, just to preserve the crowns of the plants until the heat of the bed is become quite moderate, for at this period too much covering would encrease the heat to a violent degree, and scorch the roots, which in strong beds we must, at any rate, be particularly watchful to guard against; the temperature of heat must therefore be every day examined by the trying sticks, and if it is found so vehement, that you judge the roots are in danger of scorching, the remedy is, to bore with a large rake-handle, &c. the sides of the bed, quite through in several places, both in the dung, and betwixt the top of the dung and the earth, that the rank steam and burning quality may evaporate at the holes; at the same time the free air will have access, and in two or three days the bed will be reduced to a moderate temperature.

When the Asparagus begins to appear, they are then to have their final earthing of four or five inches depth of more mould all over the crowns of the roots, and the frame and glasses to be put on. Observe as follow.

At this period, i. e. that of the first appearance of the buds, prepare some light, rich, finely-broken earth, sufficient to mould them the above depth; at the same time, in order to secure the outsides of the said final earthing, it is proper to form a sort of border, or empalement, round the top of the edges of the bed, four or five inches high, which is done either with a thick straw-band, or by raising the outside banking an additional four or five inches, either of which, as just observed, is necessary not only to secure the sides and ends of the earth, but also to support the frame a due height, the bottom of which should stand nearly as high as the surface of the final covering of earth, so as there may be full scope between the earth and the glasses for the buds to shoot. But in respect to the above empalement round the top of the bed, that instead of forming it by banking higher with earth, it is more customary to fix a wreath of straw-bands round the top of the first banking, to serve that purpose; this the London gardeners call wreathing the bed. It is done thus: when the buds first appear, make a large straw-band or rope, four or five inches thick, and long enough to go round the bed; then upon the top of the banking, exactly in the place where the frame is to stand, place this band round singly in a neat and regular manner, fastening it with pegs stuck through the sides of it into the earth, and when this is fixed, directly earth the buds as high as the said wreath, or about four or five inches deep, as above noticed, so as there may be now in the whole, about five or six inches depth of earth all over the crowns of the plants; then if the heat of the bed is become of a moderate temperature, it is proper to put on the frame, resting it upon the top of the above wreath or straw-band; or in default of this, set it immediately on the top of the banking, having been previously raised as above; after this, if you are anxious to have long buds, as is the case with the market gardeners, you may lay an inch depth of more earth, so as to make the whole full six inches thick.

The bed being now finally earthed and framed, and the heat is become moderate, the glasses or lights are to be kept constantly upon the frame, which on nights should be covered with mats, or dry long litter, but must be uncovered every day, except in uncommonly severe weather, for it is of importance to admit as much light and sun as possible, to promote a green colour in the tops of the buds;

and as to the admission of fresh air, if the heat is moderate, the glasses need only be shoved a little open in fine days, especially if you require the plants to be drawn up quick; but by admitting a larger portion of air, the buds rise slower, and will acquire a larger size and greener colour, on which consideration some, in the spring-made beds, take the glasses entirely off a few hours in fine mild dry days, particularly when the heat is considerable at the first appearance of the buds after the bed is framed.

At this time also, examine the temperature of heat in the bed. When it has been made about three weeks, if it is but a small bed, only for one or two three-light frames, the heat will begin to decline considerably, which should be renewed by a lining of hot dung applied to the sides: do not omit this, particularly when the buds begin to appear through the last covering of earth, if you should see occasion, though beds of more considerable length seldom require lining till after the first breaking or gathering of the buds; then adding a good lining, it will maintain the bed in due temperature fifteen or eighteen days longer, which is as long as the roots continue yielding any tolerable produce. See LINING BEDS.

In about five or six weeks after the bed is made and planted, we may expect Asparagus fit to gather; when the buds are from two to four or five inches high above the earth, they are of the proper size.

The method of gathering them in hot-beds is, by breaking the buds off near the root, and is done by thrusting the finger and thumb into the earth, and by a gentle twist the buds will readily break. For the supply of a family, the buds may be gathered every other day, or oftener, if necessary; but for market, the gardeners seldom make more than three principal gatherings, or breakings, from the same bed, that is, one every week for three weeks, and the second breaking is generally the best, which in Covent-garden market is sold from ten to thirty shillings a basket, each basket consisting of about 300 buds, and which of those they call ware, are often very large and fine for the season. But the Rev. Mr. Hanbury, in his Body of Gardening, says, the forced Asparagus brought to Covent-garden market, is scarcely bigger than wheat-straws, which he attributes to the ignorance of the gardeners, in which, however, as well as in the true culture of forcing Asparagus, that gentleman is greatly mistaken; for the London gardeners

having considerable practice in that article, many of whom force upwards of a hundred lights annually, that they generally excel most others in the culture of forced Asparagus, and supply the markets therewith in great perfection, especially from about Christmas till the arrival of the natural crops. Indeed, in the best-managed beds, there will, besides the main crop of large buds or ware, be many of middling growth, and many small buds or sprew; so the gardeners sort them accordingly for market, into ware, middlings, and sprew, the latter of which is sometimes not much thicker than large straws.

Of the ASPARAGUS FRUTICOSA, or Shrubby Asparagus, including also the Dragon-tree, one of the Palms, but now ranged by Linnæus as a species of Asparagus.

Besides the esculent species of Asparagus already treated of, there are several other species in the same genus, mostly of shrubby growth, exotics of the green-house and stove.

The species of most esteem are,

¹ ASPARAGUS *Albus*.

White Prickly Portugal Asparagus.] Asparagus, with shrubby very white stalks, and flexible branches, growing four feet high, ornamented with short, fine, chaffy, deciduous leaves, in clusters from one point, and sharp spines under each tuft of leaves.

² ASPARAGUS *Declinatus*.

Declinated Bristly-leaved African Asparagus.] Asparagus, with several shrubby, erect, smooth stalks; infirm declinated branches, closely covered with bristly evergreen leaves.

³ ASPARAGUS *Acutifolius*.

Acute-leaved Portugal Asparagus.] Asparagus, with shrubby, crooked, smooth, whitish stalks, growing about four feet high; small, rigid, prickly-pointed, evergreen leaves, in clusters from the same point.

⁴ ASPARAGUS *Retrofractus*.

Retrofracted Great Prickly Larch-leaved Asparagus.] Asparagus, with shrubby very crooked stalks, rising eight or nine feet high, emitting infirm reflexed branches, adorned with long, fine, narrow, evergreen leaves, in clusters from one point, and a single sharp thorn advancing under each tuft of leaves.

These four species flower here annually, which, like the common Asparagus, are very inconsiderable, and are seldom succeeded by seeds in England.

Their Culture, &c.

The above four species are exotics of the green-house, so must always be kept in pots, and managed

managed as the other plants of that department. See GREEN-HOUSE PLANTS.

Their propagation may be readily effected by slipping the roots in March or April.

If seed can be procured, they may also be raised abundantly that way, by sowing it in pots in March or April, and plunge them in a hot-bed, just to bring up the plants, which in August will be large enough for transplanting into separate pots.

¹ASPARAGUS *Draco*.

The Draco Arbor, or Dragon-tree, from the Cape Verd Islands.] Asparagus, with a large single or unbranching trunk, rising twelve or fourteen feet high, the top crowned with a circular cluster of sword-shaped, pointed leaves, a yard or more in length, placed singly, without foot-stalks round the stem, and hang down on every side in a singular manner, but rarely flowers in England.

From this plant flows, by incision, a red gummy juice, of medical property, commonly called Dragon's Blood.

This species is an exotic of the hot-house, and retained in many of our gardens, as a plant of singular growth and appearance, bearing resemblance in growth and leaves to the *Yucca*, or Adam's Needle.

It is of the Palm kind, most of which are of singular growth. See PALMÆ, &c.

The propagation of this plant is by seed, which is procured from abroad, sown in pots, and plunged in bark hot-beds; by which assistance the plants will soon come up, giving occasional waterings, and when three inches high, transplant them into separate pots, continuing them always in the stove, except in the months of July and August, when they may be exposed in the open air.

During summer they must be frequently watered, which must also be performed in winter with moderation.

ASPERIFOLIÆ Plantæ, Rough leaved Plants, and in antient botany the name of a class, consisting of plants whose leaves are rough to the touch, and have four naked seeds; of which are *Anchusa*, or Bugloss; *Borrago* Borage; *Cynoglossum*, Hound's-tongue; *Symphytum*, Comfrey, &c. the leaves of all of which are simple, alternate, and attached to the stems and branches, without any foot-stalk.

ASPHODELUS, Asphodel, or King's-Spear, so called from the resemblance of its spiked flowery stalk to a royal scepter.

The plants of this genus are herbaceous flowery perennials, with fleshy fibrous roots,

producing annual stalks two or three feet high terminated by long spikes of many liliaceous flowers of ornamental appearance.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA consists of one petal, cut into six spear-shaped spreading segments, and at bottom a globular nectarium of six valves. STAMINA, six subulate arched filaments, alternately long and short, attached to the valves of the nectarium, and oblong incumbent antheræ. PISTILLUM, a globular germen within the nectarium, awl-shaped style, and truncated stigma. PERICARPIUM, a globular fleshy capsule of three cells, filled with triangular seeds.

There are but three distinct species, all of which have fleshy fibrous roots.

The species are,

¹ASPHODELUS *Luteus*.

Common Yellow Asphodel.] Asphodelus with an upright, unbranching, large, round, leafy stalk, growing near three feet high, adorned half-way with numerous long, triangular, hollow, sharp-pointed leaves, and many starry yellow flowers, forming a long erect spike from the middle of the stalk upward.

²ASPHODELUS *Alba Ramosus*.

Branching Great White Asphodel.] Asphodelus with branching unleaved stalks a yard high; sword-shaped, long, hollow, flexible leaves, in large tufts directly from the root, and in the midst of them the stalk, emitting many side branches, adorned upward with long spikes of many large, starry, white flowers, having a purple line running down each segment.

³*Variety.*] ASPHODELUS *Alba non Ramosus*.

Unbranching White Asphodel.] Asphodelus, with simple or unbranching leafless stalks a yard high; sword-shaped, very narrow, flexible leaves from the root, and amongst them issue the stalk, upright, without branches and leaves, terminated by a very long spike of many starry snow-white flowers.

⁴ASPHODELUS *Fistulosus*.

Fistular, or Hollow-leaved Minor White Asphodel.] Asphodelus with upright, branching, leafless stalks, eighteen inches high; awl-shaped, striated, fistular leaves, hollow like a pipe, rising in a large tuft from the root, in the midst of which issue the stalks, dividing upward into a few branches, adorned at top with starry white flowers striped with purple.

Variety.] *Fistular-leaved Annual White Asphodel.*

The roots of all these Asphodels consist of many thick fleshy fibres, connected at top into one common head; to those of the second and third,

third, hang many oblong thick tubers, all of which roots are of perennial growth.

The leaves and stalks rise annually from the roots in spring, and perish in autumn, after they have flowered and perfected seeds.

The flowers are numerous on each stalk, surrounding them from the middle upward, forming a spike of innumerable buds, opening in successive order; each separate flower consists of one leaf, or petal, deeply cut into six segments, so as to appear so many different petals, opening in June, continuing in successive order a month or six weeks, and are succeeded by plenty of ripe seeds in autumn.

Culture, Propagation, &c.

All these three species demand attention as plants of ornament, as during their bloom they make a noble appearance, and may be employed as choice furniture for the embellishment of the principal compartments of the pleasure ground.

They succeed in any common soil and situation, and are of easy culture.

Their propagation is easily accomplished by seed, and by parting their roots. Sow the seed in autumn or spring in a bed of light earth, and in April or May the plants will appear, which in autumn or spring after transplant into nursery-beds, six inches distance, where they will flower the following summer, and in autumn after remove them to the open borders.

By dividing, or slipping the roots, they may be increased plentifully, which may be performed in autumn or spring. Plant the slips directly where they are to remain, and they will all flower the following summer.

ASTER, Starwort, so called from the figure of its radiated flower.

The Asters are mostly herbaceous, fibrous-rooted, flowery plants; some are annual, but the greater part are hardy perennials, producing annual stalks of different statures, from one to five feet in height, the whole adorned with simple leaves, and terminated at top by compound radiated flowers. See RADIUS. There are also some shrubby plants of the green-house.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a scaly, imbricated, general cup, containing numerous florets. COROLLA is compound and radiated; many funnel-shaped hermaphrodite florets form the disk; and flat female florets, three-parted at

the end compose the border, or radius. STAMINA, five filaments, and cylindric antheræ. PISTILLUM, an oblong germen, slender style, and bifid stigma; and in the female florets, the style is crowned by two stigma, which are oblong and revolute. PERICARPIUM, none, and a single downy seed succeeds each floret.

There are upwards of thirty species, several of which produce large and elegant flowers; and those of an annual species, called *China Aster*, are remarkably grand and beautiful; some of the perennials are also very spacious and showey, all of which adorn our gardens in autumn.

First of the annual sort, which is,

ASTER Chinenfis.

The China Aster, or Annual Starwort, from China, or Queen Marguerette.] Aster with only one stalk from the root, dividing into many spreading branches, growing about two feet high, ornamented with oval, angular, indented foot-stalked leaves, and every branch crowned by one large beautiful radiated flower, appearing in August, September, and October.

Varieties of this are.] China Aster, with single white flowers—single blue flowers—single purple flowers—single red flowers,—with double white flowers—double blue flowers—double purple flowers—double red flowers,—and with variegated blue-and-white flowers; all of which varieties, in their single state, consist of a broad yellow disk, encompassed by a series of flat spreading florets, forming the circumference, or radius; but the double flowers have many series of such florets continued to the very centre.

All the varieties are but of one summer's duration, rising from seed in spring, flower and perfect seed plentifully in autumn, and perish root and branch in November; so a fresh supply must be raised annually.

Their Culture.

This species *Aster Chinenfis* is one of the most elegant and showey annuals that ornament our gardens, all the varieties of which are curious furniture for the embellishment of the common borders; and as they are of easy culture, may be obtained plentifully in every garden.

Their propagation is by seed sown annually in March, April, or beginning of May, in a hot-bed, or warm border, from which the plants are to be transplanted into the borders.

Be careful to procure seed of the different varieties, as white, blue, red, &c.

The

The seed is commonly sown in a moderate hot-bed; it will, however, grow freely in a warm border, if sown about the middle, or latter end of April, or beginning of May, but by the aid of a hot-bed, just to raise the plants, it will forward them sooner, by almost a month, to a state of flowering. Sow the seed either on the surface, or in small drills drawn with the fingers, and cover it a quarter of an inch deep with fine earth, and when the plants appear, inure them betimes to the open air, previous to their being transplanted, and give frequent waterings. See ANNUAL PLANTS.

In May or June, when the plants are three inches high, transplant them into the natural ground in the places where they are to remain to flower, taking opportunity of showery weather, and let them be properly disposed in every border, and other compartments contiguous to the principal walks, lawns, &c. a yard, at least, distance from one another, where they will make a grand show in August, September, and October, especially if there are varieties of different colours.

For some other particulars in their culture, see ANNUAL PLANTS.

If any are wanted for pots to adorn courtyards, &c. some of the finest double sorts of different colours should be selected as soon as they shew bloom; so take them up with large balls about their roots, and plant one in each pot, giving water plentifully.

To save seed of this species, it should be gathered only from the perfect double flowers of the most lively colours, which will be ripe the end of September and October, taking opportunity of dry days, to cut off the heads as they ripen.

The hardy perennial sorts are,

¹ASTER *Tradescanti*.

Tradescant's Virginia Starwort, erroneously called Michaelmas Daisy] After with numerous, erect, branching stalks, about four feet high, adorned with oblong acute-pointed leaves, broad at the base, which half embrace the stalk, and all the stalks and branches terminated by pale blueish flowers, appearing in October.

²ASTER *Amellus*.

Amellus, or Italian Starwort.] After with numerous, upright, firm stalks two feet high, ornamented below with spear-shaped, blunt, three-veined, rough entire leaves, and the tops crowned by corymbus clusters of large flowers, on naked foot-stalks, having a golden centre, and bright blue radius, appearing in October and November.

³ASTER *Alpinus*.

Alpine Dwarf Starwort.] After, with upright unbranching stalks about a foot high, garnished with spear-shaped hairy leaves, the radical ones blunt, and each stalk surmounted by one large blue flower, appearing in June and July.

⁴ASTER *Novæ Angliæ*.

New-England Starwort.] After with many erect hairy stalks about five feet high, decorated with spear-shaped entire leaves, growing alternate; their base half surround the stalk, and all the stalks terminated by panicles of large violet-purple flowers, appearing in August and September.

⁵ASTER *Altissimus*.

Tallest Philadelphia Purple Aster.] After with upright, unbranched, hairy stalks eight or ten feet high; oblong pointed hairy leaves; their base half embrace the stalks, and each stalk terminated generally by three large reddish-purple flowers, appearing in November.

⁶ASTER *Grandiflorus*.

Great Blue Pyramidal Aster, or Catesby's Virginia Starwort.] After with stalks a yard high, emitting many side-branches, adorned with spear-shaped, reflexed, rough leaves, and every branch crowned by one large blue flower, having a rough calix, appearing in the end of October and November.

⁷ASTER *Puniceus*.

Purple-stalked American Aster.] After with upright purple stalks three feet high, garnished with spear-shaped, sawed, rough leaves; their base half embrace the stalk, and each stalk terminated by a corymbus cluster of pale blue flowers, growing singly on alternate foot-stalks, appearing the end of September and October.

⁸ASTER *Linifolius*.

Flax-leaved Aster.] After with strong erect stalks about a yard high, sending forth many side-branches, forming a corymbus, narrow, acute-pointed, entire, alternate leaves; their base half embrace the stalk, and every branch terminated by one blue flower, appearing in August and September.

⁹ASTER *Undulatus*.

Waved-leaved Aster.] After with branching stalks about a yard high, heart-shaped waved leaves, downy underneath; their base embrace the stalks, and each branch terminated by an ascending spike of whitish-blue flowers, appearing in September.

¹⁰ASTER *Ericoides*.

Heath-like Bushy Starwort.] After with slender very branchy bushy stalks about three feet high,

high, closely garnished with very narrow entire leaves, and each branch terminated by a small whitish flower, having leafy foot-stalks, appearing in October.

¹¹ASTER *Cordifolia*.

Cordated Broad-leaved Aster.] Aster with slender stalks about two feet high; heart-shaped, pointed, sharply serrated, foot stalked leaves, and the upper parts of the stalk dividing into many branches, terminated by panicles of white flowers; in September.

¹²ASTER *Glaber*.

Smooth Peach-leaved Aster.] Aster with branching stalks about five feet high; oblong, spear-shaped, acute, serrated, smooth leaves, and all the branches dividing at top into several spreading foot-stalks, each ending in a large pale blue flower, appearing in October.

¹³ASTER *Rigidus*.

Stiff-leaved White Virginia Aster.] Aster with branchy stalks about three feet high, very narrow alternate leaves, and each stalk and branch terminated by one white flower, appearing in November.

¹⁴ASTER *Tenuifolius*.

Narrow Belvedere-leaved American Aster.] Aster with branching stalks four or five feet high, very narrow entire leaves, and all the branches ending in long spikes of whitish-blue flowers, appearing the end of October.

¹⁵ASTER *Concolor*.

Single-stalked Virginia Starwort.] Aster with single or unbranched stalks four feet high; oblong, oval, entire, downy, close-fitting leaves, and each stalk terminated by a loose spike of blueish flowers, appearing about Michaelmas.

¹⁶ASTER *Divaricatus*.

Divaricated White American Aster.] Aster with stalks about two feet high, divided at top into forked diverging branches, garnished with oval sawed leaves, and terminated by umbellated clusters of white flowers, appearing the beginning of September.

¹⁷ASTER, *Novæ Belgicus*.

New Holland Starwort.] Aster with stalks about four feet high; spear-shaped, slightly-sawed, close-fitting leaves; all the stalks paniculated, and all the branches of each panicle terminated by one blue flower, appearing the end of August.

¹⁸ASTER *Tripolium*.

The Tripolium Aster, or Sea Starwort.] Aster with stalks two feet high, producing unequal branches; spear-shaped, entire, fleshy, smooth leaves, and terminated by a corymbus cluster of blue flowers; in July and August.

Of the above species, the first four or five sorts are those most commonly cultivated.

All these perennial Asters have fibrous very spreading perennial roots, but annual stalks, which rising annually in spring, continue their growth all summer, flower and perfect seed in autumn, and then die down to the root.

Their Culture.

They disdain no common soil of a garden, and will succeed almost any where.

Most of them produce considerable tufts of stalks, forming a large bush, which being closely covered with leaves and flowers, they make a very showy appearance late in autumn, when other flowers are scarce, so are well calculated for large open compartments, or in assemblage with common shrubs, and to adorn the boundaries of home-lawns, or the borders of walks carried round out-shrubberies, &c.

The propagation of all the sorts is effected with facility, by dividing their roots in autumn, winter, or spring.

The root you intend to encrease from may either be taken up and divided, or with a spade separate part of it as it stands, and so divide that part into as many separate slips as it will admit of.

The smallest slip will readily grow and flower the following autumn, and in a year or two will encrease to a great bunch; and some sorts spread so considerably, that it is necessary to reduce them every two or three years, either by cutting in the roots on each side, or by taking them entirely up, and divide them, so plant a necessary supply of the best slips, and throw the rest away.

Most of the sorts may also be encreased by cuttings of their flower-stalks in May and June in a shady border, so that if any sort afford root off-sets sparingly, recourse may be had to this method.

The green-house sort is,

ASTER *Fruticosus*.

Shrubby African Starwort, from the Cape of Good Hope.] Aster, with a shrubby stem, growing a yard high, sending out side-branches, adorned with narrow leaves, in clusters from one point, and long naked foot-stalks from the sides of the branches, each supporting one blue flower, appearing early in March.

Variety.] Shrubby Aster with white flowers.

Both these varieties must always be kept in pots, in order to be wintered in a green-house.

Their

Their propagation is by cuttings of the young branches in spring or summer, planting them in pots, which plunge in a hot-bed, just to strike the cuttings; afterwards move them to the full air during summer.

ASTRAGALUS, Milk-Vetch, including also the *Tragacantha*, or Goat's Thorn.

This genus consists of herbaceous annual and perennial flower-plants, and some of shrubby growth, all of them adorned with winged leaves, and papilionaceous or butterfly-shaped flowers.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX is monophyllous, and five-parted at top. COROLLA is papilionaceous; the standard long, erect, blunt, and reflexed on the sides; the wings and keel of equal length, and shorter than the standard. STAMINA, nine united filaments, and one single, having roundish antheræ. PISTILLUM, a taper germen, subulate style, and blunt stigma. PERICARPIUM, a pod of two cells, and kidney-shaped seeds.

There are upward of twenty species; those of them principally cultivated in the English gardens are,

¹ASTRAGALUS *Alopecuroides*.

Fox-tail Alpine Biennial Milk-Vetch.] Astragalus with upright hairy stalks a yard high, ornamented with long-winged leaves, of about twenty pair of oval lobes, terminated by an odd one; and from the places of the leaves proceed large, cylindrical, close-fitting spikes, wholly covered with down, out of which appear yellow flowers, succeeded by woolly pods; flowers in June and July.

²ASTRAGALUS *Galeiformis*.

Goat's-Rue-leaved Oriental Perennial Astragalus.] Astragalus with upright smooth stalks four feet high, adorned with long-winged leaves, of about fourteen to twenty pair of oval lobes, ending in an odd one; and from the places of the leaves, long hanging spikes of yellow flowers, succeeded by triangular pods, appearing in June and July.

³ASTRAGALUS *Christianus*.

Great Yellow Oriental Perennial Milk-Vetch.] Astragalus with erect stalks a yard high, large long-winged leaves, having many pair of oval lobes, ending in an odd one; and all along the stalks, from the angles of the leaves, proceed globular close-fitting clusters of large bright yellow flowers, appearing in July.

⁴ASTRAGALUS *Cicer*.

The Cicer Sylvestre, or Globular Podded Perennial Astragalus.] Astragalus with prostrate

stalks three feet long, winged leaves, of about ten pair of small oval lobes, terminated by an odd one; and from the angles of the leaves grow small spikes of yellow flowers, succeeded by globular swollen pods, flowering in July.

The first of these species is a biennial plant; the other three are perennials.

They are all very hardy, and will prosper in any of the common borders, or shrubby clumps, and flower and perfect seed annually.

Their propagation is by seed. Sow it in spring in a bed or border of common earth, and the plants will soon come up; all they require is weeding till autumn, when they should be transplanted into the places where they are to remain, when they will flower next summer.

As the Fox-tail Astragalus is apt to die away after it has flowered, some plants should be raised annually.

⁵ASTRAGALUS *Tragacantha*.

The Common Tragacanth Shrub, or Goat's-Thorn.] Astragalus with many shrubby, procumbent, prickly, white stalks and branches, spreading every way a foot or two in length, adorned with winged, silvery-white leaves, of six, eight, or ten pair of lobes, ending in an odd one, having their foot-stalks terminated by a sharp thorn, and white flowers in clusters from the sides and end of the branches, appearing in June and July, but not succeeded by seeds in England.

Varieties of this are.] Goat's-thorn with oval lobes to the leaves—with spear-shaped-lobes—with spear-shaped, pointed, very downy lobes—and with purple flowers, red flowers, &c.

This species and varieties retain their leaves long, and when they drop, the foot stalks remain in form of acute thorns, and as armature to the plants.

They succeed in the shrubberies in a warm dry situation, but as they are somewhat tender while young, some should also be kept in pots, to have occasional shelter of a frame or green-house during winter.

Their propagation may be effected easily by seed, if it can be procured, sowing it in a bed of common earth in April; but in default of seed, they may also be increased plentifully by slips and cuttings of their young shoots in April or May, planting them in pots, which plunge in a moderate hot-bed about six weeks, giving occasional shade and water; and harden them gradually to the open air.

ASTRANTIA, Masterwort.

This genus furnishes two species of herbaceous perennials, growing from one to two feet high, ornamented with large divided leaves, and crowned by umbellate flowers.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, the flower is umbellate, each umbel formed, of four or five smaller ones: the general calix, or involucre, consists of eight or ten leaves; that of the small umbel, of about twenty, which are long, coloured, and spreading. COROLLA, each umbel have many florets, each formed of five erect, bifid, incurved petals. STAMINA, five filaments. PISTILLUM, an oblong germen, two styles, and simple stigma. PERICARPIUM, an oval two-parted fruit, having two seeds.

The species are,

¹ASTRANTIA Major.

Great Black Masterwort.] Astrantia with upright stalks about two feet high; many large, spreading, radical leaves, divided into five large, oval, deeply-ferrated lobes; those on the stalk trilobate and pointed, one leaf at each joint, and the top of every stalk and branch crowned by an umbel of flowers.

Varieties.] Great Masterwort, with purple flowers—with white flowers.

²ASTRANTIA Minor.

Lesser Black Masterwort.] Astrantia with stalks about a foot high, digitated or fingered leaves, of seven or eight deeply sawed segments, and all the branches terminated by the umbels of flowers.

The roots of these plants are large, fibrous, spreading, black without, and of many years duration.

The plants are very hardy; they are considered chiefly as plants of ornament; tho' they effect no great figure, they however afford variety in large gardens, where it is necessary to have many plants of easy culture.

Their propagation is by seed in the common ground, or by parting the roots, both of which may be performed any time, in open weather, from October till March.

ATRAPHAXIS.

This genus retains two shrubby plants of the green-house, garnished with small simple leaves, and clusters of two petalous flowers.

Class and order, *Hexandria Digynia*.

Characters.] CALIX, two coloured permanent leaves. COROLLA, two roundish petals. STAMINA, six capillary filaments, and roundish antheræ. PISTILLUM, a compressed ger-

men, no style, but two stigma. PERICARPIUM none, the single seed being enclosed in the calix.

The species are,

¹ATRAPHAXIS Spinosus.

Prickly Oriental Atraphaxis.] Atraphaxis with a woody stem and branches four or five feet high, armed with sharp spines; small, spear-shaped, ash-coloured, smooth leaves; and clusters of white flowers from the ends of the branches, appearing in August, but no seed in England.

²ATRAPHAXIS Undulata.

Waved-leaved Smooth African Atraphaxis.] Atraphaxis with shrubby, trailing, unarmed stalks; garnished with small, oval, waved, curled leaves; and greenish-white flowers from the angles of the leaves, appearing in June and July, but no seed in England.

These two species must always be kept in pots, to be moved to a green-house in winter.

Both the species are easily propagated by cuttings in spring and beginning of summer.

ATRIPLEX, Orach, or Arach; also the *Halimus*, or Sea-Purslane Shrub.

This genus furnishes herbaceous and shrubby plants; the former are considered chiefly as esculent culinary herbs, the latter as plants of ornament, being adorned with curious silvery leaves.

Class and order, *Polygamia Monoecia*.

Characters.] Hermaphrodite and female flowers apart on the same plant. CALIX, five oval, concave, membranous-bordered, permanent leaves in the hermaphrodites, and two large, plane, erect, acute ones in the female flowers. COROLLA, none. STAMINA, five filaments, and double antheræ. PISTILLUM, an orbicular germen, two-parted style, and reflexed stigma. PERRICARPIUM none, the seed being lodged in the calix.

The species are,

¹ATRIPLEX Hortensis.

Garden Herbaceous Orach.] Atriplex with large triangular leaves, and when it runs to seed, shoots up erect herbaceous stalks; flowers in June and July, and ripen seeds in August.

Varieties.] Garden Orach with dark green leaves—whitish-green leaves—with purple leaves.

All these varieties are annual herbs; they were formerly much cultivated in kitchen-gardens, for culinary purposes, in the manner of spinach, and require exactly the same culture, the seeds being sown where they are to

to remain annually in spring for summer use ; also in autumn, to stand the winter for spring service, hoeing the plants to four or five inches distance.

¹ATRIPLEX *Halimus*.

The Halimus, or Sea-Purflane Tree.] Atriplex with a shrubby stalk, branching out widely on every side, grows four or five feet high, ornamented with white, silvery, deltoid, entire leaves, being shaped like the Greek letter *Delta*, remaining all the year, and effects a singularly agreeable variety at all seasons, but the flowers have no beauty.

It is a maritime plant of Spain, Portugal, and Virginia, but succeeds here in the full ground.

¹ATRIPLEX *Portulacoides*.

Common Sea-Purflane.] Atriplex with a shrubby stalk, sending out numerous wide-spreading branches, grows three or four feet high, very bushy, adorned with numerous, ovate, narrow, whitish, silvery leaves.

This is a sea-side plant of England, and is sometimes admitted in gardens.

These two shrubby Atriplexes, by their silvery-coloured leaves, effect an agreeable contrast, in assemblage with other shrubs, in any part of the pleasure-ground.

Their propagation is by cuttings planted in a shady border in spring and beginning of summer ; they will readily take root, and be fit to transplant in autumn.

ATROPA, *Belladonna*, or Deadly Night-Shade ; and the *Mandragora*, or Mandrake.

This genus retains two hardy herbaceous perennials, and one shrubby plant of the green-house, garnished with simple leaves, and bell-shaped flowers, cultivated in gardens more for singularity than utility or beauty.

The *Mandragora*, or Mandrake, so called from the feigned resemblance of its large, long, fleshy root, to the human figure, was always ranged as a distinct genus, till Linnaeus lately discovered its characters to be the same as the *Atropa*, and so ranges it as a species of that genus.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is monophyllous, swelling, acutely five-parted at top, and permanent. COROLLA is monopetalous, bell-shaped, with a short tube below, swelling, five-parted, and spreading above. STAMINA, five awl-shaped filaments attached to the base of the corolla, connected below, and large assurgent antheræ. PISTILLUM, a semi-oval germen, filiforme style, and oblong transverse stigma. PERI-

CARPUM, a globose bilocular berry, sitting on the calix, containing kidney-shaped seeds.

The species are,

¹First species, ATROPA *Belladonna*.

The Belladonna, or Deadly Night-Shade.] Atropa with herbaceous, strong, branching, purple stalks, four or five feet high, ornamented with large, oval, entire leaves, placed alternate ; and from the angles or places of the leaves, proceed many long foot-stalks, each supporting one bell-shaped, brownish-purple flower, succeeded by large shining black berries of deadly quality.

It flowers and ripens its fruit from June or July until Michaelmas.

This is a wild plant of Britain, but being a robust, conspicuous perennial, is admitted in many gardens, to form variety in the pleasure-ground. It ought, however, to be disposed with great caution out of the way of children, on account of the noxious quality of the fruit, which being the size and colour of black cherries, appear very beautiful and tempting ; and taken internally, they cause a stupor, delirium, and convulsions, and without the speedy and copious use of acids, such as vinegar, juice of lemons, &c. soon prove mortal.

The fresh leaves of this plant applied to hard tumours, and schirrhous swellings on the breast, are a certain remedy.

The propagation of this species is effected abundantly by slips or off-sets from the root in autumn or spring ; also by seed in a bed of common earth, from which transplant the plants in autumn.

²Second species, ATROPA *Mandragora*.

The Mandragora, or Mandrake Plant.] Atropa with a very large, long, parsnep-like root ; no stalk, but the root crowned with many large pointed leaves, devoid of foot-stalks, about a foot long, almost half as broad, spreading in a circular cluster, and in the midst rise the foot-stalks of the flowers three inches long, each supporting one whitish-green flower, succeeded by large, round, yellowish berries.

It flowers in March or April, and the fruit ripen in July.

This species is very durable in root, which are said to remain sound and vigorous half a century at least.

It is retained in many curious gardens, as a plant of singularity.

Its propagation is by seed, in a bed of light earth, sown in autumn or spring, either where they are to remain, or the plants may be transplanted

planted in autumn into different borders for variety, placing them in dry ground, where they will abide an age, encrease exceedingly in magnitude, and flower and perfect seed annually.

This is supposed to be the Mandrakes mentioned in Scripture, and the fruit are said to have vast power in procuring fruitfulness to women.

Of the root of this plant many ridiculous stories have been invented by quacks, relative to its fancied resemblance to the human form, it acquiring considerable substance, and strikes three or four feet deep, dividing frequently into large, long, fleshy forks, which impostors made to resemble the legs, thighs, and arms of the human body, and shewed it about the country, advancing strange accounts of its singularity, too idle to be regarded; such as its sensation of feeling, by emitting groans at the approach of violence, and to cause instant death to him who should attempt to root it out of the ground. So greatly were these impostures palmed upon the credulous formerly, that in default of the real *Mandragora*, Mandrakes, or images, were formed of the large roots of briony, effected by opening the earth in spring about a strong-shooting young plant, without disturbing the lower fibres, so fixing a figure-mould about it, then filling in the earth, and by autumn the root assumes the desired form; they also sometimes artfully carved a large root, as it grew, to a sort of resemblance, so filling in the earth again, and by the end of summer the carved parts would be crusted over, so as to hide the artifice.

³ Third species, *ATROPA Frutifcens*.

Shrubby Deadly Night-Shade of Spain] *Atropa* with a shrubby very branching stalk, grows seven feet high, garnished with roundish oval leaves alternately, and footstalks in clusters from the wings of the leaves, supporting yellowish brown-striped flowers, which are not succeeded by berries in England.

This plant must always be kept in pots, and wintered in a green-house.

It may be propagated by seeds procured from abroad, which must be sown in pots in spring, and plunged in a hot-bed, just to raise the plants.

AVENUES In gardening Avenues are considered to be large strait walks, bounded on each side with one or two rows of noble forest trees, designed sometimes as a principal way from the common road to the mansion of

a country seat, and often to form views, or to lead to different districts.

In the ancient style of gardening, these kind of walks were considered as great ornaments; no country seat was without them, and many still permit the old ones to stand: sometimes several were extended from the mansion in different directions; frequently a grand one was extended directly from the main front of the dwelling to the nearest common road; others were designed chiefly as ornaments, and some as views terminating in that of some distant natural object, or that of the united work of art and nature, and some were concluded by domestick works, as an obelisk, temple, alcove, ruins, or other garden edifices; sometimes by natural or artificial mounts, woods, groves, recesses, bowers, &c. which Avenues, when disposed with propriety, and planted with different noble trees, assumed a grand appearance.

But modern planners rarely admit any such thing as a regular Avenue in their designs; even often demolish entirely the old ones of a century or two standing, copying nature to such an extreme, that nothing having the appearance of art or regularity can be admitted.

Regular Avenues, however, about extensive seats, detached in parks, &c. always exhibit an air of grandeur, though I should advise to have the principal front of the mansion entirely open, or unincumbered with these or any kind of plantation; for it is a great absurdity to hide a good front, and obstruct the prospect: no avenue can therefore be admitted with propriety in that part of the ground. A spacious lawn of grass should always be exhibited in due extension in the most conspicuous fronts of the dwelling. See **LAWNS**. But in a direction from the wings, detached at some considerable distance, Avenues might with more propriety be introduced and extended on each side of spacious lawns, serving by way of boundary, and backed up next the lawn with shrubs and lower trees, disposed irregularly, and if the Avenues are carried in an oblique direction, the lawn will widen gradually, and the prospect will be more copious, or Avenues might be admitted at some distance from either end or back front of the dwelling, in either of which situations an Avenue may be extended towards any common road, village, or town, one or more serving as the common entrance or Avenue leading to the habitation, others by way of ornament, &c. and in extensive situations, Avenues might occupy

A V E

occupy different parts at a distance directed towards woods, groves, or edifices, and particular districts about an estate, which when of considerable width, and bounded on each side with the noblest progeny of the forest, gives an air of dignity to the site.

These Avenues should be planted with the stateliest trees; and an assemblage of different sorts, effects the more agreeable variety.

The width of the Avenue should never be less than sixty feet, but when it is to be extended any considerable length, a hundred feet wide is not too much, especially when we consider that as the trees grow up, the branches on the opposite sides continuing to approach each other, which by degrees greatly contract the view, so that if a considerable width is not at first adopted, the Avenue would in time appear very narrow and trifling.

The trees in the rows on each side should be planted thirty feet distance at least, that the different trees may have full scope to display their heads, and each sort exhibit itself conspicuously, according to its own natural form.

The sorts of trees proper for Avenues, are of the deciduous tribe; the elm, lime, platanus, beech, chestnut, horse-chestnut, ash-tree, or white poplar, sycamore, Norway maple, Virginia maple, walnut-tree, wild cherry-tree; all of which are of lofty growth; and an assemblage of all, or part, will have a fine effect disposed in Avenues.

Sometimes evergreen trees are used for Avenues: where this is intended, the most proper sorts are various species of the *Pinus*, or pine-tree, including all the sorts of firs, most of which attain a great height and magnitude, with beautiful spreading heads, and are extremely ornamental.

Rural Avenues, as common ways or roads through a park, &c. to a habitation, may be contrived either in a direct line, or carried round in a moderate sweep, or the course directed in two, three, or more, very gentle bends, or easy serpentine turns, each side ornamented with different sorts of trees, thinly dispersed in a rural taste; that is, some placed singly, others in groupes of two, three, or more together, exhibiting them variously, some breaking forward, others standing more back; and for the greater diversity, may introduce here and there a clump of tall flowering shrubs, having, the whole, the single trees, groupes, and clumps, so considerably detached, as to admit of a full prospect of the

A U T

adjacent lawns, fields, or plantations, during the whole excursion of the Avenue.

The trees that form any sort of Avenue, whether deciduous or evergreen, should all be permitted to take their own natural growth.

AURANTIUM, the Orange-tree. See CITRUS.

AURICULA *Ursi*, Bears-ear, or Auricula. See PRIMULA.

AUTUMNAL *Plants*, Plants that flower in autumn.

AUTUMNAL SEASON. The Autumn season being very often mentioned in the course of this work, it may be necessary to observe, that in regard to the numerous works directed to be done in that season, we commonly consider it to be from about the beginning or middle of August, till the latter end of November, in which period many works of sowing, planting, and propagation, is successfully performed.

As for instance, many sorts of esculent plants are sown to stand the winter for spring, such as cabbage, cauliflower, carrots, lettuce, spinach, onions; and in October and November, beans, peas; planting out also early cabbage-plants; likewise cauliflowers under hand and bell glasses, where they are to remain, and pricking others thick in frames, to stand till spring; planting out lettuces on warm borders, and in frames, to stand the winter; also celery in shallow trenches, for spring service; making and spawning mushroom beds, for winter and spring use.

Many sorts of fibrous-rooted flower-plants are increased at this season, by dividing or parting their roots, particularly in the months of September, October, and November, when the flower-stems decay, and the slipped or divided parts will all flower the year following.

Likewise, from the middle of September until the middle or end of November, is a proper time to transplant from one place to another almost every kind of hardy fibrous-rooted perennials, as directed each under its proper genera.

It is also a proper time to plant all sorts of bulbous flower-roots that were taken up in summer, which being now planted, exhibit an early spring and summer bloom.

Seeds of many sorts of flowers are also now to be sown, which do not grow so freely when sown at other seasons, as expressed in their respective places in the course of the work.

In this season also, from the middle of September till the end of November, is the best time.

time to plant cuttings, and make layers, for the propagation of numerous hardy trees and shrubs.

Seeds of many sorts of hardy trees and shrubs are also to be sown in October and November.

The principal Autumnal planting season for all sorts of hardy trees and shrubs, both fruit, forest, and ornamental kinds, is from about the middle of October to the end of November.

AXILLA, the angle formed by the stem and branch; and leaves proceeding immediately from that part are termed axillary leaves.

Likewise flowers proceeding from the angle, formed by the leaf and branch, are termed axillary flowers.

AZALIA, American Upright Honeysuckle.

This genus furnishes our shrubberies with two hardy, deciduous, flowering shrubs, of moderate growth, ornamented with oblong simple leaves, and funnel-shaped flowers in clusters.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is small, five-parted at top, coloured, and permanent. **COROLLA** is a funnel-shaped petal, having a long tube below, and divided at top into five reflexed segments. **STAMINA**, five filaments inserted into the receptacle, and simple antheræ. **PISTILLUM**, a round germen, long permanent style, and blunt stigma. **PERICARPIUM**, a roundish capsule of five cells, and numerous roundish seeds.

The species are,

¹**AZALEA Viscosa.**

Viscous Flowered White Azalea.] Azalea with several shrubby branching stems, rising three

or four feet high, garnished with spear-shaped, narrow-based, rough-bordered leaves, in clusters towards the end of the branches, and with all the branches terminated by white, hairy, glutinous flowers, coming out between the leaves in clusters.

²**AZALEA Nudiflora.**

Naked-flowered Red Azalea.] Azalea with several woody branching stems, rising seven or eight feet high, decorated with oblong, oval, smooth, entire leaves, placed alternate, and long footstalks proceeding from the sides of the branches, supporting clusters of large red flowers, having the longest stamina.

The flowers of both these species are beautiful and fragrant, and bear some resemblance to the common Honeysuckle, being formed each of a single petal, having a long tube, divided at top into five reflexed parts. See the *Characters*.

They flower annually in July, but never perfect seeds in England.

For purposes in gardening, both the species are well adapted for the shrubbery, and will succeed in any common soil, though they delight most in shady moist places.

As to their propagation, they not producing seed here, are commonly increased by laying the young shoots in autumn, or spring; or that, as many stems or shoots generally rise from each root, some of these may be taken off with roots, and planted either in nursery rows, or where they are to remain.

The seeds of both sorts are also often imported from America by the seedsmen, which should be sown in spring in a warm situation, or their germination may be facilitated by aid of a moderate hot-bed.

B.

BACCA, a berry, defined to be a pulpy pericarpium, or seed-vessel, generally round or oval, without a valve, inclosing several seeds, mostly placed upon foot-stalks within the pulp, as in the gooseberry, currant, raspberry, &c.

The berry does not naturally gape or burst for the dispersion of seeds, being designed to be performed by means of animals.

By Linnæus, not only the currant, gooseberry, raspberry, strawberry, &c. but also

the very different fruits; the apple, pear, quince, medlar, love-apple, orange, lemon, and pine-apple, are all denominated berries.

BACCHARIS, Ploughman's Spikenard.

Of this genus are three exotic shrubs of the green house, growing five or six feet high, ornamented with simple leaves, and compound flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Cha-

Characters.] Compound flower. CALIX is a cylindrical, acutely scaly, general cup containing many florets. COROLLA, the general flower is equal, the hermaphrodite and female florets are intermixed. STAMINA, five filaments in each hermaphrodite floret, and cylindrical antheræ. PISTILLUM, in all the florets an oval germen, filiforme style, and bifid stigma. PERICARPIUM, none; the seeds are one under each floret, crowned with down.

The species are,

¹BACCHARIS *Ivaefolia*.

Iva-leaved American Baccharis.] Baccharis with shrubby branching stems, four or five feet high; long, spear-shaped, venose, dentate-sawed leaves; and whitish flowers from the sides and ends of the branches, in July and August.

²BACCHARIS *Neriifolia*.

Oleander-leaved African Baccharis.] Baccharis with shrubby stems rising six or seven feet high, branching out upward, garnished with spear-shaped stiff leaves, a little indented at top, and greenish-white flowers, in close spikes from the ends of the branches, in July and August.

³BACCHARIS *Halimifolia*.

Halimus-leaved Baccharis, or Virginia Ground-sel-tree.] Baccharis with a shrubby branching stem, rising seven feet high, ornamented with oboval, emarginate-dentated, glaucous-coloured leaves, continuing all the year, and many small white flowers, in September and October.

They flower here annually, and the first and second sorts furnish seeds; but the third flowering late, rarely produce any in England.

These three shrubs are generally considered as green-house plants; they are however so hardy as to be able to struggle with our ordinary winter in warm shrubberies, in which departments they are sometimes planted to take their chance; but as they are subject to be much cut in severe frosts, some of each sort should also be potted, in order to be housed in winter.

The propagation of all three sorts is by layers and cuttings of the young shoots, any time from March till Midsummer, in pots or the common ground, giving occasional shade and waterings, particularly the cuttings, and they will be rooted and fit to transplant into separate pots in autumn.

They may also be raised from seeds, in a bed of common earth, in March or April.

BACCIFERÆ *Planta*, Bacciferous, or Berry-bearing Plants, and such that have a bacca, or berry, for their seed-vessel or pericarpium. See PERICARPIUM.

BARBA, a Beard, alluding to bearded plants, being such whose leaves or flowers are terminated by a bunch or tuft of down, or hairs. The *Mesembryanthemum Barbatum* furnishes an example.

BARBATUS *Flos*, bearded, gaping, or ringent flowers.

A flower having two lips, the lower of which is the beard, *Barba*, and stands opposed to *Galea*, the upper-lip. Vide COROLLA *rignens*, and GALEA.

BARK-BEDS, Hot-beds formed of tanner's-bark, and such that support the most uniform and durable temperature of heat, and the best calculated hot-beds yet known, for the cultivation of all sorts of tender exotics from the warm parts of America, Asia, and Africa, that require the continual aid of artificial heat to maintain them in this country.

These hot-beds, with a little assistance, as hereafter directed, often support a regular temperature of heat almost a twelvemonth.

It is these bark or tan hot-beds that are universally used in hot-houses, and are called the bark-beds, there being a cavity or pit formed within the hot-house almost its whole length, six or seven feet wide, and three deep, and walled round with brick; see HOT-HOUSE; and in which pit is made the bark hot-beds, the use of which is to plunge the pots in, containing all sorts of tender exotics from warm countries; and by the aid of which principally, with occasional assistance of actual fire, we are enabled to cultivate in the greatest perfection that very curious exotic perennial, the *Bromelia Ananas*, or pine-apple; also all other tender plants from every quarter of the world; for by the joint aid of these bark hot-beds, and fire heat, we are able to imitate, within the hot-house, the temperature of distant climates, so far as to raise and exhibit in health, duration, and beauty, every known plant, herbaceous, or woody, from the warmest parts of the globe, which before the use of bark-beds were thought impossible to be cultivated in England.

These bark hot-beds are also made in pits formed in the open ground, distinct and detached from the hot-house, which pits are walled round, having a frame of wood at top, for support of glass lights, and are designed chiefly

chiefly for the propagation of tender plants from seed, cuttings, suckers, &c. without incumbering the hot-house, or stove departments, which are often so crowded, as not to admit of such work; these are commonly called pits, or bark pits, and are very useful where there are great collections of tender exotics, and serve also as a nursery for young Pine-apple plants, for the annual supply of the stove, or main pinery. See BARK PIT.

Bark hot-beds are also sometimes used in the culture of melons, which, on account of their regular and durable heat, generally afford excellent crops: the Dutch practise this with great success. See *CUCUMIS Melo*, the Melon.

These kind of hot-beds are also used with great success in forcing-frames, for the production of early fruit, such as apricots, peaches, grapes, &c. See FORCING-FRAMES.

Hot beds made of this material, are considerably more regular and durable in heat than those of dung, and not, like them, liable to injure plants by steam; and as to duration, they commonly maintain a due temperature of heat almost a year, with the assistance of forking or turning over two or three times, together with the addition, once, of about one third part of new tan; but they must be entirely renewed every autumn or spring, as hereafter directed.

This article tanner's bark, of which these hot-beds are made, is the bark of the oak-tree, chopped or ground to pieces for the use of the tanners, which after being used by them in their tan-vats, is fit for the gardeners purpose, wherewith to make hot-beds, for which, there being now so great a demand all over the kingdom, the tanners sell it at a good price, which about London is commonly seven and six pence per cart-load of sixty bushels, or in proportion. The places about that city where the greatest choice is to be had, is principally in the Borough of Southwark, where are numerous considerable tan-yards, particularly in the parts called the Grange-road, Long-lane, Barnaby-street, Bermondsey, and places adjacent.

In the choice of the bark or tan, observe there are different sorts, such as the large or coarse, the middling, and the small sort, which last is the worst of all; the large sort is longest before it heats, and the heat is apt to be violent at first, though of the longest duration; the middle-size sort heats moderately soon, and regular, seldom very violent,

and is pretty durable; the small sort heats the soonest of any, though more weak, and soon becomes earthy, whereby its fermenting property is soon exhausted, and should never be used alone, where any other can be possibly procured; this sort however is now very common in the tan-yards, for the tanners find a considerable advantage for their use by grinding the bark small, because it goes the farthest.

Therefore where there is choice, the middle size sort is to be preferred, or a mixture of this and the large, and but as little of the small as possible.

Likewise observe to procure such that is fresh, i. e. that has been about a week or fortnight, or at most not more than three weeks or a month out of the tan-pit, rejecting such that have lain so long as to have become black and earthy.

When the tan is brought home, if it is very wet, it is eligible, previous to forming it into a bed, to dispose it in small heaps or ridges for two or three days, or till it is drained of the redundant moisture, which would greatly retard its regular fermentation.

The time of year to make these beds is principally in autumn and spring. In hot-houses, for pine-apple plants, &c. they are commonly made in September or October, to have a good heat during winter; but when they are required for the purpose of raising tender exotics from seed or cuttings, &c. they are generally made in spring, as also for melons, and forcing-frames.

The dimensions of the bed is to be the width and length of the pit in which it is made, and a yard deep.

In making the bark-bed, the tan is to be thrown into the pit prepared for its reception, as before observed; and a hand or two beginning at one end, work the whole up regularly with the tan-fork to the bottom, carrying the bed to its full width and depth on before you; for it is not proper to tread much upon the bark when formed into a bed, which would render it too compact, and prevent its regular fermentation, raising the whole three or four inches higher than the kirb or top of the wall of the pit in which the bed is made, to allow for settling.

As soon as the bed is made, thrust two or three long sticks into the bark in different parts, to draw up occasionally to feel their lower end, to inform you of the temperature of the heat.

In

In a fortnight, or perhaps in a little more or less time, the bed will be arrived at a due temperature of heat for the reception of the plants, of which you are to judge by the above mentioned sticks, observing, if it is intended for pines, or other plants in pots, they are to be plunged immediately into the bark, there being no occasion for earth thereon, as in dung hot-beds; and when you proceed to plunge them, it is eligible to lay a board across to stand upon, to prevent treading the bark too close; likewise having regard, if the heat is apparently violent, to plunge the pots only half way, less or more, as you shall judge necessary to preserve the roots of the plants from being scorched, and when the vehement heat subsides, plunge them down to their rims.

The bed being thus made, it will support its first heat a quarter of a year at least, when if, by the trying sticks, you find it upon the decline, it is to be revived by stirring up, or turning over the bark, which, if it is the large, or the middle-size sort, it will not at this time require any augmentation of fresh tan. Previous to the turning, first take up all the pots, then beginning at one end, fork up the bark quite to the bottom, breaking the lumps, and turn the whole over, and directly plunge the pots as before; this operation will renew the heat, and support it in a proper temperature two or three months longer, when the same work of turning, with the addition of about one third part of fresh tan is necessary, blending the whole together, continuing to repeat the same operation of turning as often as you shall find the heat decline; about twice or thrice in the course of the year is sufficient.

It is always necessary, in March or April, to add about one third, at least, of fresh tan, previously clearing out all the most crumbly or earthy old stuff at top and next the outside, then throwing in as much new as will fill up the pit, fork the whole up neatly, old and new together.

Every autumn, in September or October, it is proper to renew entirely the bed in the hot-house and bark pits; for after it has been made ten or twelve months, the bark will be greatly exhausted both in heat and substance, so as to become earthy, which, at the time you intend to make the new bed, should be previously screened, and all that passes through the screen to be cleared away; so adding to the remaining old, as much new tan as will fill up the pit, then working the whole regularly toge-

ther with the fork. See HOT-HOUSE. But where the old tan is very earthy, it is proper to clear it out entirely, and make the bed wholly of new materials.

BARK-PIT. In hot-houses a Bark-pit is the cavity, wherein the bark hot-bed is made. See BARK-BED, HOT-HOUSE, &c.

A Bark Pit is also an erection, covered with glass, formed separately or distinct from the hot-house, but in a manner connected with it, as its chief use is by way of a nursery for that department, being useful for raising all kind of tender exotics from seeds, cuttings, suckers, &c. and retaining them till a certain period, or till arrived at a proper state of growth, to be removed to the stove, and is particularly useful for the young ananas, or pine-apple plants, in rearing and nursing them till of a proper size to be placed in the succession-house or fruiting-stove.

These pits are commonly erected in a defended sunny situation contiguous to the hot-house, and are formed most commonly with a wall of brick or stone, with flues behind, and with a frame of wood at top for the support of glass.

The dimensions are, the length from ten to as many feet as convenient, six or seven wide, and sunk not more than eighteen inches in the ground in case of wet, and the whole to be walled round with brick from the bottom, raising it four or five feet in front, and five or six behind, the ends in proportion, with two flues near the upper part of the back wall, to make fires occasionally in winter, to warm the air, and a timber plate or kirb, framed round the top with cross-bars three feet four inches asunder, for the support of glass lights.

In this pit a bark-bed is made the whole length and width, and about a yard deep in tan, which will be ready for any sort of tender plants, seeds, and cuttings, and its heat is continued by forking it over, and a small addition of new tan, as directed under the article BARK-BED.

But when pits are required principally for raising tender plants from seed, cuttings, &c. in spring or summer, there need not be any flues or fire place.

BARLERIA. It contains several hot-house exotics, herbaceous and shrubby plants, rising three or four feet high, having simple, oblong, or oval leaves; monopetalous, funnel-shaped, blue flowers, with four stamina, and one style.

Q

They

They are rare in England, but may be raised from seeds in the stove.

BASELLA, Climbing Night-Shade of Malabar.

This genus retains two climbing, herbaceous, succulent, hot-house perennials, garnished with simple leaves, and monopetalous pitcher-shaped flowers.

Class and order, *Pentandria Trigynia*.

Characters.] **CALIX**, none. **COROLLA**, a pitcher-shaped, fleshy, permanent petal, connivent and six or seven-parted at top. **STAMINA**, five filaments attached to the corolla. **PISTILLUM**, a globular germen, three slender styles, with oblong stigmas. **PERICARPIUM**, the permanent corolla assumes the appearance of a fleshy berry, inclosing one seed.

The species are,

¹**BASELLA Rubra**.

Red Malabar Night-Shade.] Basella with climbing, strong, succulent, deep purple, herbaceous stalks and branches, mounting, upon any support, eight or ten feet high, adorned with heart-shaped, succulent, purple leaves, and foot-stalks from the sides and ends of the branches, supporting reddish flowers.

²**BASELLA Alba**.

White Small Malabar Night-Shade.] Basella with climbing, small, succulent, very branchy green stalks; oblong-oval, waved, flaccid leaves; and long foot-stalks from the sides of the branches, supporting white flowers.

Variety.] Basella with small purple stalks, and variegated leaves.

The flowers of both species appear from June till October, and are succeeded by plenty of seeds.

The plants are preserved here in stoves, more for singularity than beauty.

They are propagated either by seed in a hot-bed in spring, or by cuttings in pots of dry light earth, plunged in the bark-bed in the stove, or any other hot-bed, moving the plants afterwards to the stove, and allow them support.

BASKETS. For the use of gardeners, different sorts of Baskets are necessary for gathering the different products, and other uses.

As for instance, that for the purpose of gathering all sorts of salad herbs for family use, flat, shallow, chip or osier Baskets, without any handle, are the most convenient, which are in dimension, from about ten or twelve, to eighteen inches diameter, and two or three

deep, which will commodiously hold, separate, all the different herbs necessary to compose a salad for a family, and which are also useful for gathering many other sorts of small herbs. The Basket-makers make vast numbers of them for the above uses, which, about London, they sell from one to two or three shillings per dozen.

For the purpose of gathering peas, beans, cabbage, carrots, and other crops required in any considerable quantity, there should be strong, deep, osier Baskets, of different dimensions, somewhat of the form of a water-pail, and from about a peck to a bushel size, with two strong side-handles at top.

Baskets of the above dimensions are also very useful to use in weeding, both in the kitchen and pleasure ground.

But in some places they make their garden Baskets round, or of a half-globular form, with an arched or bow-handle cross-ways at top, and are very useful for light work.

The kitchen-gardeners about London, for the purpose of carrying their ware to market, have strong osier Baskets of different sizes and shapes, for which they have different terms, as boats, junks, maunds, sieves, &c. The boats are large flat Baskets two or three feet broad, and eight or ten inches deep, with two handles at the rim, used chiefly to put up such goods that cannot bear hard, or close packing, such as lettuce, celery, cauliflowers, small salad-herbs, &c. also many sorts of bunched esculents, as bunches of young carrots, onions, leeks, fans of horse-radish, sticks of parsneps, hands of radishes, bunches of young coleworts, and such like. Junks are from about half a bushel to a bushel size, flat-bottom, eight or ten inches deep, widest at top, where are four strong handles, much used for packing kidney beans, which, with the help of large cabbage-leaves, they generally heap considerably more at top than there is within the Basket. Maunds are upright narrow Baskets about two feet deep, wider at top than bottom, having two handles, and usually open round the middle of the sides, and are used wherein to pack spinach, parsley, sprouts, and other small culinary herbs. Sieves are flat-bottomed, upright-sided Baskets, about a foot deep, without handles, and from about a peck to a bushel measure in dimensions, being equally as wide at bottom as the top, and are used for packing various small plants; likewise fruit, particularly gooseberries, currants, cherries, plums, &c. which differ-

rent

rent kinds of Baskets, though moderately cheap, stand the market-gardeners in an annual expence of from ten to twenty or thirty pounds, or more, according to their extent of ground.

Fruit-baskets for domestic use, should be of different sorts; that for gathering small fruit for table, such as strawberries, raspberries, mulberries, gooseberries, currants, cherries, &c. there should be several small, round, shallow, white Baskets, of two or three different sizes, holding in measure from about a quart to half a gallon, &c. from about six to ten or twelve inches diameter, and the rims not more than two or three deep, wider at top than bottom; so that every sort of these small fruit may be gathered in a separate Basket, and in that manner carried in to be put up in the desert. For the larger kinds of fruits, such as apricots, peaches, nectarines, plums, figs, pears, &c. it is proper to be furnished also with different-sized, small, shallow Baskets, as above, at least for the purpose of sending in the fruit for the desert, each sort in its separate Basket, which should be previously lined at bottom, and round the sides and edges, thinly with vine leaves, the more effectually to preserve the beauty of the fruit, and set it off to the best advantage, especially if some are also thinly disposed between the larger sorts, as apricots, peaches, &c.

Pottle baskets are the most convenient for sending quantities of strawberries, raspberries, and mulberries, choicer sorts of early cherries, and the most delicate sorts of small plums, to market, or to any distance; these are very small, upright, chip Baskets, holding about a quart, being ten or twelve inches deep, very narrow at bottom, and not more than four or five inches wide at top, where there is a cross handle. The London gardeners use vast quantities of them, buy them at ninepence or a shilling per dozen, which when filled with fruit, they pack many together in a large Boat-basket, so send them to market on men's heads, or otherwise.

Sieve-baskets, already mentioned, are the most useful for sending large quantities of gooseberries, currants, common cherries, grapes, plums, and other stone fruit, and soft pears, to market, which should never be filled higher than the brim, placing a little fern, or short hay, at top, so that, as being of an equal width at bottom and top, may, if requisite, place one upon another, without pressing upon the fruit. The cherry farmers in Kent and Hertfordshire, &c. use all these

sort of Baskets for sending their cherries, and other soft fruit, to market.

Baskets are also useful for packing many sorts of plants in pots, when intended to be sent in a growing state to any great distance, for which use the Baskets are prepared in width and depth, in proportion to that of the pot containing the plant; and if the plant hath a full head, the edge of the basket is closely set round with long osier, or willow rods; so when the plant is placed in the basket, its head is tyed together neatly in two or three different parts; then the rods are gathered together at top, so as to surround and defend the head of the plant, which, when fastened, will have a pyramidal form, and if it is cold weather, and the plants are of the tender kinds, mats should also be neatly sewed round the whole.

Large Baskets, about three feet deep, and two and half diameter, are useful in pleasure-grounds, for carrying off the mowing of short grass, leaves, &c. placing the basket on a water-barrow, which Basket will contain three times as much as the body of a common wheel-barrow; so that the work is done with more expedition, and with less wheeling backward and forward upon the grass and walks.

In many places the gardeners make their own Baskets, particularly in North-Britain, where, in time of hard frosts, when nothing can be done abroad, the men are occasionally employed in making Baskets for the ensuing year's service, at which some are very dextrous; but they commonly make them all of a half globular form, with a bow handle cross-ways at top, as before described.

For the principal materials for making Baskets, see SALIX.

BASONS, or Reservoirs of Water, for use and ornament in gardens.

For useful purposes, Basons of water in gardens are essentially necessary for watering plants in summer, particularly such that are obliged to be planted out in time of drought; also for watering beds of young seedlings of any sort in dry hot weather, plants in hot-beds under glasses, and all sorts of plants in pots; and that water exposed to the sun and air in Basons, &c. is considerably more salutary for the growth of all vegetables, than raw sharp water, drawn immediately out of wells: but sometimes there are natural ponds, reservoirs, or other waters, in the neighbourhood of gardens, so conveniently situated for watering, as to render the expence of making a Bason

a *Bafon*, merely for that purpose, unnecessary.

For ornament, regular *Bafons* of water were in great esteem in formal designs of gardens, and were commonly situated in large opens, or centres, at the termination or meeting of several walks; they were often so contrived, as to have playing fountains, or jets d'eau, as the French term them, in the middle, with Neptune and his train, and other devices; but the regular figure of a *Bafon*, &c. is now thought too formal to be admitted in our present designs in imitation of nature: this, however, is according to the fancy of the owner or planner of the design, since the form and dimension may be varied at pleasure. The figure was commonly either circular, oval, octagonal, or square, which, when of moderate dimensions, were called *Bafons*, but if large, were termed pieces of water; but a *Bafon* might be formed according to nature, in any well-designed irregular figure, so as to have a desirable effect.

One great article in making *Bafons*, or any pieces of water, is to consider whether a proper supply of water is to be obtained at all times of the year.

Another thing is the means of making them hold water completely at all seasons.

This is done the most effectually by laying the bottom and sides of the cavity thereof with strong clay, twelve, fifteen, or eighteen inches thick, according to the quality of the natural soil; for the more the soil inclines to a loose or sandy texture, the greater thickness of clay must be allowed; but where the soil is naturally loamy or clayey, there will be little difficulty in making it hold water with a moderate thickness of additional clay.

In default of clay for the above purpose, chalk is sometimes used in countries where it abounds, first forming it into a powder, then forming into a sort of mortar, and with this the bottom and side walls are formed, beating and ramming it hard, observing the thickness as above.

Some also, instead of clay, work the bottom and sides a foot thick with masonry of brick or small stones laid in terrass, and plaister it over with two or three inches thickness of cement, which is two thirds of powdered tile to one of lime, beating it well with as little water as possible, into a strong mortar, and after this is laid on, rub it over with oil or bullock's blood, and it hardens under water like stone.

The depth of *Bafons*, or any ornamental piece of water, need not be more than three feet, though some are considerably deeper; but four feet at most is depth enough, even when intended to have a boat thereon, or to keep fish in for breeding. The sides of the cavity of the *Bafon* should be formed with a gradual slope, from the top of the circumference to the intended depth, and the whole laid with clay, to render it water-tight, as before observed, and a few inches of gravel over that, to preserve it, and render the water clear; and the surrounding surface of ground should be laid with grass from the edge of the water to some considerable distance each way, though in the old designs, perpendicular walls of masonry laid in terrass, were often formed round the sides of the cavity, with a stone coping at top, corresponding with the general surface.

No high banks, or stiff slopes, should be raised as boundaries to a *Bafon*, or any piece of water intended for ornament, to obstruct the distant prospect thereof; and if so that the water will unavoidably lie low, it is proper to slope off the ground gradually from some distance on every side to the intended surface of water, so as the superficies of the circumference may more apparently correspond with the general surrounding surface; for the slope to the water, if necessary to have any, should be easy and natural, that the whole surface of water may appear as conspicuous as possible at some distance, and the whole so contrived, that the water may always appear nearly as high as the superficies of the margin of the *Bafon*.

The situation for ornamental *Bafons*, &c. should be in some conspicuous part, as far as may be consistent with the means of having it properly supplied with water at all seasons, especially in summer, when it is the most desirable both for use and ornament; and where a large work is intended, we should also contrive it in the most eligible part, where as little digging as possible is necessary to form the cavity.

As to the dimensions or size, that, if designed merely for the use of watering plants, from ten to fifteen or twenty feet diameter may be sufficient; but when required for ornament, it may be any size or form, in proportion to the extent and form of the garden, or according to the supply of water that can be easily obtained, or the nature of the soil for holding the water; for where water is scarce, or that the soil is loose and sandy, nothing

nothing very extensive should be attempted, as the bringing clay from a distance to lay a large Bason fifteen or eighteen inches thick, as must be the case in light sandy ground, would be attended with a considerable expence; and if, after all, water was not to be had in sufficient quantity to keep the Bason always full, how great would be the disappointment? But where water is copious in the neighbourhood, either in an adjacent river, brook, or running spring, so situated that a sufficiency can be readily conveyed at a moderate expence to the part of the ground required, a Bason of a more capacious dimension may be undertaken; and if, with the above circumstance of plenty of water, there is a natural loamy or clayey soil of proper depth, they are particular advantages, and in which cases, Basons of considerable extent are sometimes easily formed with very little artificial claying, and some without any, where there is a good natural depth of clay, and a large supply of water: however, in loose, hollow, sandy, or any light ground, a good coat of clay must be allowed all over the bottom and sides.

In setting out the dimensions of the Bason, observe, that where a full coat of clay is necessary, it must be staked out three feet six inches, at least, wider than its intended width, to allow for a fifteen inch wall of clay on each side, and five or six inches of gravel over the clay; it should also be twenty inches, or two feet deeper than you design the depth of water, because the bottom ought to be clayed fifteen or eighteen inches thick, and five or six of gravel.

Particular care should be observed to stake the superficies of the circumference perfectly level, that the water may show regular distance every way from the margin. The manner of taking the level is as directed under the articles *LEVELLING* and *WATER*.

In digging out the cavity of the Bason, begin towards the middle, and excavate the earth to the intended depth, as above, then work off the sides regularly with a moderate slope from the edge of the circumference to the bottom of the Bason.

When the cavity of the Bason is formed, let it be well rammed and smoothed, then the clay is to be brought in, which should have been previously well wrought over and trod; see *CLAY*; and begin laying the bottom in the middle, being careful that no stones, sticks, or such materials, be mixed therewith,

to occasion fissures to let off the water; spread it regularly, a little at a time, and tread it with men's naked feet, casting water thereon frequently, ramming it also from time to time with wooden rammers, observing, if it is loose ground, lay it fifteen or eighteen inches thick, and see that every part be well kneaded, that there be not the least vacancy, for the water will escape at the smallest cranny, and occasion great trouble hereafter. During the work, if the weather is dry, cover the clay, as you lay it, with mats or moist litter, to prevent its cracking, continuing the claying regularly each way from the bottom to the top of the circumference of the Bason; and as soon as the whole is clayed, cover it immediately with a stratum of coarse gravel four or five inches thick, which secures the clay, and renders the water always clear; and when thus far finished, let the water in as soon as possible. Then proceed to finish the superficies of the circumference, and lay it all round with turf from the water-edge to some considerable distance every way, as the situation shall admit, observing to lay it as far down on every side as the water will apparently stand, but not so as to form any slope, distinct from that of the immediate surrounding superficies; for if any at all is necessary, it should be contrived in one regular slope, which is the more agreeable to character, as the surface of water will more apparently correspond with the circumjacent surface of the ground, and appear the more conspicuous at a distance; so that when the surface of the water lies unavoidably much lower than the general surface, the ground on every side should be sloped off gradually to some considerable distance, as before hinted, that the descent to the water may be as easy and natural as possible, so as to admit of walking with pleasure upon any part thereof.

Sometimes, in regular pieces of water, one or more artificial swells, in imitation of nature, are artfully disposed in particular parts near the side, so as to have a characteristic appearance.

BASS, among gardeners, is pieces of the threads or strings of garden bairn mats, extremely useful as ligaments in the culture of numbers of plants, and the most cheap and ready bandage for the use of gardeners.

As for instance, it is the best bandage that can be used for binding grafts and buds; also for the tying up the stalks or stems of most sorts of flowering plants, and which, if fresh, will

will endure a year; likewise is very useful in the kitchen garden for many purposes, such as tying up the leaves of early cabbages, lettuce, endive, &c. to whiten and promote their heading; also for bunching up various sorts of pot and medical herbs for winter service, and for many other uses.

The Bafs for all these purposes should be quite fresh, not taken from such old mats as have been occasionally used in the garden; and that where there is much tying, it is eligible to allot a mat or two entirely for that purpose, keeping it in the dry, and not drawing the Bafs, as is often practised, from the mats that are designed for other uses, which soon spoils them.

When it is wanted for tying, it should be drawn out regularly, and cut into equal lengths; and to render it more pliable and tough, should be dipped in water, then the gardener should tuck it in his apron-string, where it will be ready for use.

BASTERIA, All-spice. See **CALYCAN-THUS**.

BAUHINIA, Mountain Ebony.

This genus comprehends seven or eight species of tender exotic shrubs and trees, producing pentapetalous flowers in spikes, having ten stamina, and a declinated style.

They are rare in England; the following are cultivated in some of our stoves.

¹**BAUHINIA Aculeata**.

Prickly Bauhinia, or Indian Savin.] Bauhinia with a prickly stem, rising fifteen feet high, having irregular branches, roundish emarginate leaves, emitting a balsamic odour like the savin-tree, and spikes of yellow flowers.

²**BAUHINIA Tomentosa**.

Tomentose Bauhinia.] Bauhinia with a smooth stem and branches, growing fifteen or eighteen feet high, heart-shaped tomentose leaves, having two semi-orbicular lobes, and long spikes of yellow flowers.

They are propagated by seeds from abroad, assisted by a hot-bed, or the bark-bed in the stove, where the plants must always remain.

BEDS are small compartments of ground, of three or four feet breadth, very necessary in the culture of many sorts of plants.

In kitchen-gardens, it is eligible to sow and prick out many sorts of small plants in Beds, having narrow alleys between, for the greater convenience of weeding, watering, gathering, &c. without trampling on the crops; as, for example, the ground intended for asparagus and strawberries should be divided into four feet wide Beds, with eighteen

inches, or two feet alleys between; onions are also cultivated to the best advantage in four feet wide Beds, having ten or twelve inch alleys; the different sorts of lettuce and endive should also be sown and transplanted into separate Beds; also early radishes, when intended to cover them occasionally. All sorts of plants that are particularly intended for transplantation, should always be sown in beds or narrow borders, so as to admit of standing to clean, water, and draw the plants, without treading upon them; also, for the same reason, all plants necessary to be pricked out previous to their final transplanting, should also be pricked in Beds, such as celery, cabbage, cauliflower, broccoli, &c. aromatic and medical herbs of all sorts should also, for the general part, be disposed in Beds with twelve or fifteen inch alleys between, particularly mint, thyme, savory, marjoram, sage, hyssop, baum, penny-royal, tansey, tarragon, feverfew, rue, &c. which method of bedding all the sorts of plants above hinted, is not only more commodious for doing the necessary work without prejudicing the plants, but also has an air of uniformity, which is ever to be observed in a kitchen garden.

The proper dimensions of Beds in this district, is four feet, or four and a half in width, the length at pleasure, with intervening shallow alleys, nine, twelve, or fifteen inches wide, so that a person in the alleys may easily reach half across the Bed, to do the necessary work to the plants, &c. without trampling them, or treading the ground hard.

In flower-gardens, when designed separately from the general pleasure ground, should be wholly divided into regular parallel Beds, of three or four feet width, with eighteen inch, or two feet alleys, especially when intended chiefly for the curious sorts of bulbous rooted flowers, such as tulips, hyacinths, &c. also for ranunculas, anemones, and other choice sorts, that, by being deposited together in Beds, they can be occasionally covered in winter, and the flowers screened from the scorching sun in summer. These Beds should be neatly edged with box. See **BUXUS** and **EDGINGS**.

The Beds of a regular flower-garden may also be laid out parterre fashion in the Chinese taste. See **PARTERRE**.

A flower seminary, or nursery for raising all sorts of flowers from seeds, slips, cuttings, parting-roots, &c. should also be divided into three or four feet wide Beds.

B E L

In nurseries for trees, the ground intended for the reception of seeds and cuttings of all sorts of hardy trees and shrubs, should also be divided into three or four feet Beds, with twelve or fifteen inch alleys between, for the reasons above-mentioned.

Beds should not in general be raised but very little higher than the alleys, unless in cases of too copious moisture; but otherwise, the surface of Beds should not be more than two or three inches, at most, higher than the level of the alley; for, when raised considerably, the alleys assume the appearance of trenches, and have a disagreeable look.

BELLIS, that beautiful little perennial the Daisy.

The garden Daisy, in all its forms and colours, are varieties only of one species, and that the common white field Daisy that adorns the meadows and pasture grounds in most parts of Europe, is supposed to be the parent of them all.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] Compound radiated flower. CALIX, a double series of small equal leaves. COROLLA, numerous small, tubular, hermaphrodite florets compose the disc, and flat female florets the radius, and a single naked seed under each floret. See COMPOSITUS Flos.

But in the full double flowers, the radius, or female florets, are encreased to the very centre, and form the doubleness. See PLENUS Flos.

The species is,

BELLIS Perennis Hortensis.

Perennial Garden Daisy.] Bellis with a fibrous perennial root, crowned by numerous small, oval, evergreen leaves, in a large tuft close to the ground; and amongst them rise many naked flower-stalks, four or five inches high, each supporting one flower.

Varieties of this are] Common garden Daisy with double white flowers—with double red flowers—with double white and red striped flowers—with variegated flowers—double scarlet flowers—double pyed flowers—double quilled or fistular flowers—double white cock's-comb-shaped flowers—double red cock's-comb-shaped flowers—double speckled flowers—Proliferous, or Hen and Chickens Daisy, the most singularly curious of all, it being a large double flower, sending out many small ones immediately from its sides all around, each supported on a short foot-stalk, the whole

B E R

regularly surrounding their common parent, appearing very ornamental.

All these varieties flower abundantly in April, May, and June, and have an exceeding pretty effect, when properly disposed in the fronts of borders in assemblage with perennials of similar growth. See PERENNIAL PLANTS.

They are extremely hardy, and prosper in almost any situation and soil.

With regard to their disposition, some plant them to form edgings, but these soon become irregular, in which order of arrangement, however, the flowers are the most conspicuous, though, for the sake of diversity, I should also advise disposing many of them in different parts of the borders, towards the front, to form round patches or tufts a yard or two distance, planting the different varieties alternately, to effect the greater variegation.

The propagation of all the varieties is by dividing or slipping the plants in autumn or spring, and the smallest slip having a fibre, will readily grow, and in one season encrease to a large tuft; if, however, they are intended to make as great a show of bloom as possible, they should not be divided too small, and the slips may be planted at once where they are to remain.

As these plants encrease considerably into bunches, they should be transplanted and slipped every year, or at least every second autumn.

This is also necessary to preserve the double state of the flowers, as, if permitted to remain long unremoved and slipped, they become small and single like the common sort.

The gardeners about London, who raise vast quantities to supply the markets in spring, always slip their store plants annually in autumn, in September or October, and plant them together in beds or borders, in rows six inches distance, planting some also in warm sunny borders, to facilitate an early bloom, for they always carry the plants to market when in flower, and the sooner this is effected in spring, the greater price they fetch.

At each time of slipping, always encrease from the largest and fullest doubles; and those that discover any signs of degeneracy to singles, cast entirely out of the garden.

BERBERIS, the Barberry-shrub, or Piperidge-bush.

This genus comprehends hardy deciduous shrubs, having simple oval leaves, and small hexapetalous flowers, mostly in small bunches.

Class

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, six concave coloured leaves, alternately smaller and larger. COROLLA, six small, oval, concave petals, and two coloured nectariums attached to the base of each petal. STAMINA, six erect, compressed, blunt filaments, and two antheræ attached to their apex. PISTILLUM, a long cylindric germen, no style, but a broad, orbicular, bordered stigma. PERICARPIUM, a cylindric, blunt, umbelicated berry, of one cell, containing two seeds.

The species are,

¹BERBERIS *Vulgaris*.

Common Barberry.] Barberry with shrubby woody stems and branches, growing eight or ten feet high, armed with thorns by threes; oval slightly-ferrated leaves, placed alternate; and yellow flowers, in numerous small long clusters from the sides of the branches, succeeded by clusters of small, bright, red berries, in autumn.

Varieties of this are] Common Barberry with red fruit, having stoney seeds—with red stoneless fruit—with white fruit—with black sweetish fruit.

The root of all the varieties is yellow; also the inner bark of the stem and branches.

²BERBERIS *Cretica*.

Cretan Box-leaved Barberry.] Berberis with many shrubby stalks three or four feet high, armed with thorns at every joint, small oval leaves, and slender foot-stalks, each having one flower, but no fruit in England.

The first species, *Berberis Vulgaris*, is the most commonly cultivated in the English gardens, and the red fruited varieties most of all; it grows wild in many of our woods and hedges, but has been long admitted an inhabitant of gardens, both as an ornamental shrub, and for the sake of its red fruit for domestic uses, which, growing in numerous little clusters, have a very ornamental appearance in autumn, and when fully ripe, are a curious and very wholesome pickle; for which use, the stoneless red sort is in most esteem; the bunches of red fruit are also in much request for garnish to dishes, and where numbers of the shrubs are cultivated, the fruit afford a good repast for birds.

They flower in May, and the red sorts ripen fruit abundantly in September.

They are excellent furniture for wilderness or wood works, or any of the large shrubbery clumps, in assemblage with common deciduous shrubs, and all the culture they re-

quire is, to reduce with a knife any rambling shoots. See SHRUBBERY.

But to have fruit as large and fine as possible, some plants may be disposed singly, trained with a single stem four feet high, then permitted to branch out to form a head, and take its natural growth, only cutting out luxuriant shoots and ramblers.

Their propagation may be effected by suckers arising annually from the root.

Likewise abundantly by layers in the common way, any time from October till March, which will be rooted and fit to transplant the following autumn; cuttings of the young shoots planted in autumn, will also many of them strike.

They may likewise be raised plentifully from seed, in a bed of common earth, in autumn, though the plants will probably not appear until the second spring.

BETA, the Beet.

This genus furnishes several varieties of useful culinary herbs, and esculent roots, of the kitchen-garden.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, a five-leaved permanent cup. COROLLA, none; five stamina; a germen under the receptacle, and two styles, succeeded by a unilocular capsule, having one seed surrounded by the calix.

There are two or three species, one of which grows wild on the sea shores, and is seldom admitted in gardens.

The garden kinds are,

¹BETA *Cicla*.

The Common Culinary Beet.] Beta with a small, oblong, white root, producing from its crown many large, oblong, succulent leaves, on broad foot-stalks; and erect branching seed-stems and stems two or three feet high, garnished with close-sitting leaves, and long spikes of greenish flowers.

Varieties of this are] Common green-leaved Beet—white-leaved Beet—Chard, or great white Swiss Beet, having very broad leaves, with thick foot stalks and ribs.

These varieties often vary from one to the other, that the seed of one frequently producing some of each sort, though, by care in saving the seed, the difference may be continued.

²BETA *Rubra*.

The Red Beet.] Beta with a large, red, eatable root, crowned by many large, succulent, dark-purple leaves; and when it shoots, sends

B E T

sends up erect stalks and branches, terminated by long spikes of flowers.

Varieties of this are] Common red Beet with a large, longish, dark-red root—turnep-rooted red Beet—with a red root and green leaves—with a yellow root.

The first of these four varieties is to be preferred for general culture.

Culture of the Common Sort and Varieties.

The first sort, Common Beet, and varieties, are choice culinary herbs, whose property resides in their large succulent leaves, which are excellent for soups, &c. also to boil and eat like spinach; and the Chard Beet is in much esteem also, for the stalks and ribs of its large leaves, which being divested of the leafy part and peeled, are great improvers of soup, also for stewing, and to be dressed and eaten like asparagus, and the leaves themselves are fine pot-herbs, as above, for all of which uses the several varieties of this species may be obtained almost the year round; for as often as the large outer leaves are gathered, the root continues sending up a fresh supply from the centre, not only in summer, but also in autumn, winter, and spring, in open weather.

All the varieties of this sort are propagated by seed sown annually in March or April, in the places where the plants are to remain.

They succeed in any common soil of the kitchen-garden, allowing each sort a separate plat or bed. Let the ground be dug one spade deep in the usual way; the seed may then either be sown broad-cast on the surface, and raked in; or, as it is a large seed, shallow drills may be drawn six inches distance for the common green and white varieties, but almost double that for the Chard Beet, sowing the seeds therein thinly, and rake the earth over them about an inch deep, and trim the surface smooth.

The plants will come up in about a month; when these have leaves an inch or two broad, they should be hoed to thin them and destroy weeds, cutting out the common green and white sorts to about six inches distance; but the Chard Beet should be allowed ten or twelve inches room every way, that their large succulent leaves may have full scope to spread.

They will be in perfection for use in June and July, and continue till next spring, observing, when you gather them, always to take the largest outside leaves; the others will

B E T

come in for use in their turn, and an abundant successive supply will rise duly in the centre from the root.

Culture of the Red Sort.

The second sort, *Beta Rubra*, is highly valued for its large red root, which in the common variety often grow twelve or fifteen inches long, and three or four inches thick, or more, upward; and those that are of the largest growth, and darkest red colour, are the most valuable: these roots being tender, sweet, and palatable, are boiled, sliced, and eaten cold, &c. are also sliced and scraped in fallads, both as an eatable ingredient, and by way of garnish; slices of the root are also in request as garnish to dishes, and they are also used as a pickle.

These roots are in perfection from the end of August until March or April, when they will shoot, and become sticky.

This sort is raised from seed annually in March or April, in the place where the plants are to remain, being careful to procure that of the best dark red sort.

It should be allowed a light, rich, deep soil, in an open exposure.

The market-gardeners often sow this sort thinly among their crops of onions, carrots, &c. that are to be drawn off while young; so that when these are gone, the Beets commence a full crop.

I should however advise to sow the principal crop separate, which, in the end, will be found to be the best culture. Let the ground be dug one good spade deep at least, and well broken, and sow the seed directly, which may either be sown broad-cast on the surface, so tread and rake it in, or, as observed of the first sort, as the seed being large, that in order to bury it more regularly, it may be sown in drills drawn an inch deep, and ten or twelve distance; or you may dot or prick it in, as often practised, with a blunt dibber, in lines the above distance, making the holes an inch deep, and eight or ten asunder, at least, dropping two or three seeds in each hole, though only one good plant must be left in each place. In May or June, when the plants of either method of sowing have leaves an inch broad, they will require thinning and cleaning from weeds. Chuse a dry day, and with an hoe cut up all weeds, and set out the plants ten or twelve inches distance, leaving no where two or more together, repeating the work occasionally to kill weeds till the plants cover the ground.

R

Some

B E T

Some of the roots will be fit to take up for use about the end of August, though they will not attain perfection until October.

In November a quantity of roots should be taken up, their tops trimmed off not too close, and then laid in sand or dry earth under shelter, to be ready for winter service.

Of saving Seed from both Species.

To save seed of all the varieties, either mark some of the best plants in spring to be left to run up, or may be transplanted in February or March into a convenient place, to have shelter from winds; they will shoot up stalks in May; in June support them with stakes, and the seed will ripen in September.

BETONICA, Betony.

The plants are herbaceous fibrous-rooted perennials, having simple leaves, and annual stalks from one to two feet high, terminated by spikes of small ringent flowers; esteemed, some as medical plants, and some for variety in gardens.

Class and order, *Didynamia Gymnospermia*.

Characters.] **CALIX** is monophyllous, tubular, five-parted, and permanent. **COROLLA** is ringent, with a cylindric incurved tube, the upper-lip roundish and entire, the lower one three-parted, the middle part broad and emarginated. **STAMINA**, two long and two short filaments, and roundish antheræ. **PISTILLUM**, a four-parted germen, awl-shaped style, and bifid stigma. **PERICARPIUM** none, four naked seeds lodged in the calix.

The species are,

¹**BETONICA Officinalis**.

Common Officinal Wood Betony.] Betonica with many oblong indented leaves on long foot-stalks from the root, and square stalks a foot and half high, terminated by interrupted spikes of flowers.

Varieties.] Common Betony with purple flowers—with red flowers—with white flowers.

This sort and varieties is a wild plant of our woods, much valued for its medical properties.

²**BETONICA Orientalis**.

Oriental Betony] Betonica with long, narrow, hairy, indented leaves, on long foot-stalks from the root, and square leafy stalks a foot and half high, terminated by a large entire spike of purple flowers.

³**BETONICA Danica**.

Large Danish Betony.] Betonica with broad, heart-shaped, radical leaves; large upright

B E T

stalks, ornamented with spear-shaped obtuse leaves, and terminated by short thick spikes of purple or white flowers.

All these are hardy plants, and will thrive in any situation.

They are propagated by seed and by parting the roots. Sow the seed in the spring, and the roots may be parted or transplanted either in the spring or autumn.

BETULA, the Birch-tree; comprehending also the *Alnus*, or Alder-tree.

This genus comprehends several species of hardy deciduous forest-trees, useful for purposes in gardening, and as underwood and timber-trees for many æconomical uses.

Class and order, *Monoecia Tetrandria*.

The flowers are produced in a cylindrical amentum or catkin, with male and female flowers on separate catkins, at a distance on the same tree; the male florets have four stamina, and the females two styles, succeeded by single seeds lodged in the scales of the amentum.

The species are,

¹**BETULA Alba**.

The White, or Common English Birch.] Betula with an erect trunk covered with a white bark, rising twenty or thirty feet high, dividing into many moderate branches, adorned with small, oval, serrated leaves, ending in points.

²**BETULA Nigra**.

Black Virginia Birch.] Betula with a large upright trunk, and spreading spotted branches, growing fifty or sixty feet high, garnished with larger, rhomboid-oval, doubly-serrated, pointed leaves, on long foot-stalks.

Varieties.] Broad-leaved Virginia Birch—Poplar-leaved Virginia Birch—Paper-Birch.

³**BETULA Lenta**.

Canada Birch.] Betula with an upright trunk and spreading branches, growing sixty feet high; large, heart-shaped, oblong, pointed, serrated leaves.

Varieties.] Dusky Canada Birch—White-paper Canada Birch—Poplar-leaved Canada Birch.

⁴**BETULA Nana**.

Dwarf Alpine Birch.] Betula with a shrubby branching stem two or three feet high, garnished with round crenated-edged leaves.

The **BETULA ALNUS**, or Alder-tree, is,

⁵**BETULA Alnus**.

Alnus, or Alder-tree.] Betula with an upright stem, having purplish bark, rising thirty or forty feet in height, dividing into many purplish erect-growing branches, adorned with

with large, round, glutinous leaves, of a deep green colour.

Varieties.] Common round leaved English Alder as above—Long-leaved American Alder—White Alder—Hoary-leaved Alder—Dwarf Alder.

All these species of *Betula* are extremely hardy, and will prosper upon almost any soil and exposure, either in large pleasure-grounds, parks, fields, &c.

For purposes in gardening, they, having trait smooth stems, may be introduced for ornament and variety in extensive grounds; their foliage will form an agreeable diversity in assemblage with other deciduous trees, but their flowers possess little beauty; they have a good effect in large wilderness and wood-works, and in ornamental plantations on the boundaries of parks and considerable lawns; also in internal clumps in parks, and some planted singly as standards in large opens.

The *Betula Alba*, or Common Birch, grows naturally in great plenty in many parts of Britain, prospers in any soil, wet or dry, boggy, stony, or sandy barren land, often sowing itself, and comes up abundantly in such places where hardly any other tree will grow; and in such ground it may be cultivated to advantage, both as a forest-tree for its timber, and as coppice or underwood, to fall every seven or eight years for poles, &c.

The timber of this tree when old is esteemed by the wheel-wrights, and turners' value it for many purposes; its lopping is excellent fuel, and the brush-wood make the best of brooms. See BROOMS.

The bark of these trees being of such durable nature, that the Swedes cover their houses with it.

Before the invention of writing-paper, the inner fine bark of this tree was often used for that purpose; hence some sorts are called Paper-Birch.

A wholesome wine is made of the juice or sap of this tree, procured in March while the sap is in motion, by boring holes in the body of large trees, and putting in faucets or taps of small elder-pipes, to conduct the liquor into bottles, so that from a good many trees several gallons may be daily collected, without injuring the trees in their growth.

Coppices are formed of these trees in waste barren land, to cut as underwood every six, eight, or ten years, for poles, for hoops, and many uses in husbandry; also for the brush-wood for birch-brooms, for which there is

a constant demand. When such coppices are intended, they should be formed of young plants, previously raised in the nursery; see their *Propagation*; from thence planted out at five or six feet distance, which in seven or eight years will be ready to cut, and will support a cutting every sixth year for the broom-men, and every eighth, tenth, or twelfth year, for poles for the hoop-benders and other uses, and for husbandry implements.

The two species of American Birch and varieties being equally hardy as the common sort, but more swift in growth, and obtain a large stature, may also be introduced in woods and other plantations among forest trees.

The *Betula Alnus*, or Alder-tree, grows rapidly in marshy watery places, or meadows contiguous to rivers, brooks, and other waters, in most parts of Britain, and is a useful tree both in its growing state, and its wood as timber and for poles for various uses, which growing freely in any moist or boggy soil, it may be cultivated to good account in any waste, marshy, or swampy grounds.

In its growing state it is most useful to secure the banks of rivers, by planting truncheons pretty close, which will grow and send up numerous suckers quite from the lower roots, which effectually prevents the banks from being undermined by the current.

These trees are also useful to form hedges, to fence and divide boggy or swampy ground.

The wood of this tree is particularly valuable for works intended to be constantly under water, such as water-pipes, sluices, pumps, troughs, piles, &c. and the turners apply it to various uses.

Coppices of these trees in boggy ground, to be cut as coppice or underwood every eight or ten years for poles, pay very well; these coppices may be formed of truncheons, i. e. large cuttings of three feet long, cut from growing trees, sharpening one end, then making holes with an iron crow two feet deep and a yard asunder, plant the truncheons two feet in the ground, they will readily grow and send up several stems, which in seven years will be large enough to fell for poles, at which time clear away entirely every other stool, so that the remainder stand five or six feet asunder, and they will afford you a fall of good poles every eighth or tenth year.

But when intended to have these or any of the Birches stand for timber, they must be left fifteen feet asunder.

The Propagation of all the Species.

The Birch-trees are propagated either by seeds or layers; the common sort afford us plenty of seeds in autumn, but that of the foreign sorts is imported by the seeds-men from America. Sow all the sorts in beds of light earth in autumn or spring, covering it about half an inch deep, and the plants will come up in April or May, keeping them clean from weeds all summer; the spring following plant them out in nursery-rows two feet and half asunder, to remain till they are three, four, or five feet high, then transplant them where they are to remain.

By layers they may be raised plentifully from a few proper stools, having been previously headed down to the ground to produce lower branches, which when two years old will be well furnished with many side-shoots, which being splashed and layed in the ground, together with all their young twigs, every one of which will grow, and be fit to be planted out in the nursery the following autumn, and the stools continue to furnish a fresh supply of layers annually.

By this method of laying, all the varieties of the foreign kinds are continued, for they vary from seed.

The Alder-tree is also propagated plentifully by seed and layers as above; also by cuttings of any size, planted in any moist or shady place, will put out roots freely, and in two or three years will become large plants of three, four, or five feet stature, when they may be planted out for good.

Large cuttings or truncheons of two or three feet long may be planted at once by the sides of rivers, brooks, &c. putting them two parts of three in the ground, they will grow, and afford a cutting for poles every seven or eight years.

BIENNIAL PLANTS; Plants, as the title *Biennial* imports, that are only of two years duration.

Numerous plants are of this tribe, which being raised one year from seed, generally attain perfection either the same, or in about the period of a twelvemonth, or a little less or more, and the following spring or summer shoot up stalks, flower, and perfect seeds, soon after which they commonly perish, or if any particular sort survive another year, they assume a dwindling and straggling growth, and gradually die off; so that Biennials are always in their prime the first or second summer.

Biennials consist both of esculents and flower-plants.

Of the esculent kinds, the cabbage, favoy, carrot, parsnep, beet, onion, leek, &c. are Biennials.

Of the flowery tribe, the Canterbury-bell, French honeysuckle, wall-flower, stock-July-flower, sweet-william, China-pink, common pink, matted pink, carnation, scabious, hollyhock, tree-mallow, vervain-mallow, tree-primrose, honesty or moonwort, &c. are all of the Biennial tribe; all of which being sown in March, April, or May, rise the same year, and in spring following shoot up into stalks, flower and perfect seeds in autumn, after which most of them dwindle, though sometimes the wall-flowers, hollyhocks, carnations, pinks, will survive and flower the following year, but the plants become straggling, the flowers small and badly coloured; it is therefore eligible to raise a supply annually from seed, although wall-flowers, carnations, and pinks, may be continued by slips and layers.

BIGNONIA, Trumpet-flower, or Scarlet Jasmine.

The *Bignonias* are of the shrub and tree kind, comprehend many species, three or four of which are cultivated in our shrubberies, and consist of climbing shrubs and an upright tree, garnished some with winged, others with simple leaves, and campanulate trumpet-shaped flowers.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX** is monophyllous, cup-shaped, and quinquifid. **COROLLA** is one bell-shaped petal, having a long tube, swelling and five-parted at top, the two upper parts reflexed, the under ones spread open. **STAMINA**, two short and two long filaments, and oblong reflexed antheræ. **PISTILLUM**, an oblong germen, slender style, and headed stigma. **PERICARPIMUM**, a bivalvate pod of two cells; containing numerous winged seeds placed imbricatum.

The plants are mostly of American growth; those cultivated in our gardens are,

BIGNONIA Radicans.

Radicant Climbing Ash-leaved Scarlet Bignonia.] *Bignonia* with climbing shrubby stalks, radican or rooting at the points, mounting upon support, thirty or forty feet high, ornamented with pinnated opposite leaves of four pair of small sawed lobes and an odd one, and all the shoots and branches terminated by beautiful clusters of large trumpet-shaped scarlet flowers.

Variety.] Radicant least Ash-leaved Bignonia with small flowers.

²BIGNONIA *Sempervirens*.

Evergreen Climbing Virginia Bignonia.] Bignonia with climbing slender stalks, twining upon, support twenty or thirty feet high; simple lanceolate-leaves placed opposite, and trumpet-shaped, erect, yellow flowers, from the sides and ends of the stalks and branches.

Variety.] Evergreen climbing four-leaved Virginia Bignonia.

³BIGNONIA *Catalpa*.

Catalpa, or Tree Bignonia.] Bignonia with an upright strong woody stem and branches, rising twenty feet high, ornamented with large heart-shaped leaves five or six inches long, almost as broad, placed by threes, and whitish yellow-striped flowers in panicles towards the ends of the branches.

The flowers of all the species are monopetalous, tubular, long, and somewhat trumpet-shaped, (see the *Characters*), appearing mostly in August, but rarely produce seed-pods in England.

As to their use in gardens, they are all employed as plants of ornament.

The first sort and variety, if planted against high walls, will soon cover them, they emitting roots at all the joints of the stalks, which strike into the joints of buildings, and mount to their tops if ever so high, where they will endure many years, and flower annually.

The second sort and variety being somewhat tender, must be planted against a warm wall, and sheltered from frost with mats while young.

The *Catalpa* is a very ornamental, hardy, deciduous shrub, or rather tree, worthy of a place in all curious shrubberies, as during the summer season, when clothed with its luxuriant beautiful foliage, no tree makes a more noble appearance, which, on account of its singular beauty, should be placed conspicuously, and some should be disposed singly upon spacious lawns, or other large opens of grass-ground, and permitted to take their natural growth.

Propagation of all the Species.

The two first species and varieties may be propagated by layers; every shoot layed will readily grow, and will flower in two or three years.

Cuttings of the strong shoots will also put out roots freely.

They may also be raised from seeds pro-

cured from America, sowing them in pots in spring, and place them in a moderate hot-bed, from which the plants must be inured to the full air in summer, sheltered in winter from frost, and in spring plant them out in the full ground; but plants thus raised rarely flower in less than six or seven years.

The *Catalpa* may be propagated by cuttings of its young shoots, aided by artificial heat, planting them in pots in spring, which plunge either in a common dung hot-bed, or in a bark-bed; they will strike in a month or six weeks, when they must be hardened to the open air, in which let them stand till October, then moved to a place of occasional shelter from frost, and in spring following plant them out in the nursery.

This plant is also raised from seed, either in a warm border, or in pots, and plunged in a moderate hot-bed, which will facilitate the germination of the seed, which is sometimes apt to remain a year before it begins to grow.

BIXA, Dying *Mitella*, Spanish *Anotta*, or French *Roucou*.

There is but one species, an evergreen shrub of the hot-house.

Class and order, *Polyandria Monogynia*.

Characters.] CALIX, a plane, obtuse, permanent cup. COROLLA, ten large oblong petals in a double series. STAMINA, numerous bristly filaments. PISTILLUM, an oval germen, slender style, and parallelly-bifid, compressed stigma. PERICARPIMUM, an oval, heart-formed, hairy capsule of two valves and one cell.

The species is,

BIXA *Orellana*.

American Bixa.] Bixa with an upright stem ten feet high, branching out into a regular head, garnished with heart-shaped pointed leaves, placed alternate, and reddish flowers in panicles from the ends of the branches, succeeded by large, pulpy, red fruit; in great request among dyers and painters.

This tender American shrub is retained here in stoves for variety.

It is propagated by seeds from America, sown in pots in spring, and plunged in a bark-bed, and the plants are to be transplanted into separate pots, and always retained in the stove.

BLIGHTS. These are infectious distempers, which often attack our fruit-trees in spring and summer, frequently destroying the leaves, blossoms, and fruit, and sometimes prove destructive to the trees themselves.

Many

Many have attempted to account for the causes of Blights. Some suppose they proceed from some particular defect in the soil; others attribute the whole to the air, whilst others are of opinion that it proceeds from the particular state of the trees themselves, especially when they assume a weakly habit; some again ascribe the distemper to easterly winds bringing vast quantities of insect eggs from a distance, or that long dry easterly winds, unaccompanied by rain or night-dews, stop the perspiration in tender blossoms, and occasion them soon to wither and decay, and by long continuance of the same weather the leaves and tender shoots are also affected in like manner, and the perspiring matter thickens to a glutinous consistence, adhering to the surface, becomes nutriment to those small animalculæ which we often find so numerous on the leaves and young shoots of fruit-trees, discoverable by the shrivelling or curling of the leaves, and which, though not generally supposed to be the first cause of the distemper, yet they spread the mischief considerably, as often, from a few twigs, they will over-run a whole tree, and spread themselves to others on every side, to the destruction often of a whole wall of trees.

Against this annoyance to our fruit-trees there is no guard, nor any certain general method of cure after the trees are once considerably attacked.

Various methods however are practised to save wall and espalier-trees when the infection appears, such as, when the distemper is slight, to pinch off all the worst leaves, to prevent its spreading; also to cut off part, or even whole shoots, when most of the leaves on them, or the shoots themselves, are infected, cutting them off below the distempered parts, and they will probably shoot out again the same or next year. After these operations frequently dash the trees with water in a morning or evening, either out of a common watering-pot, or a hand-engine, the latter of which is the most effectual, which by a daily repetition for a week, will have a great effect in preventing the disaster from spreading, if not totally eradicate it, when not very formidable.

Some strew tobacco dust over the trees, or sprinkle them with water in which tobacco-stalks have been infused.

There is a species of Blight called a fire-blast, the most certain and sudden destruction to fruit-trees of any, as in a few hours it not only destroys the leaves and fruit, but fre-

quently the branches, and sometimes whole trees, and for which there is not the least remedy.

A sort of pestilence sometimes attacks wall-fruit trees, which causes the leaves and shoots to become black and clammy, generally terminating in the destruction of the tree, and will run through the whole walling, if not stopped by removing the distempered plant, and washing that part of the wall with lime or strong brine.

BLITUM, Blite, or Strawberry-spinach.

The plants are herbaceous annuals of the ornamental kind, rising with stems two or three feet high, garnished with spinach-shaped leaves, and clusters of strawberry-like fruit; hence the name Strawberry-spinach.

Class and order, *Monandria Digynia*.

Characters.] CALIX is tripartite, spreading, and permanent. COROLLA none. STAMINA, one small bristly filament, and double antheræ. PISTILLUM, an oval, pointed germen, two styles, and simple stigma. PERICARPIUM, a small, oval, compressed capsule, having one globular compressed seed the size of the seed-vessel.

The species are,

¹BLITUM *Capitatum*.

Capitated Strawberry-Spinach.] Blitum with upright herbaceous stalks two feet and half high, garnished with triangular spinach-shaped leaves, and flowers in clustered heads at the joints and crown of the stalks, succeeded by red strawberry-like fruit.

Variety.] Capitated White Strawberry-Spinach.

²BLITUM *Tartaricum*.

Tartarian Strawberry-Spinach] Blitum with herbaceous stalks, rising a yard high; triangular, acutely-indented, spinach-shaped leaves; and single heads of flowers, growing only from the sides of the stalks, succeeded by small, red, strawberry-like fruit.

³BLITUM *Virgatum*.

Dwarf Virgate Strawberry-Spinach.] Blitum with a slender stalk about a foot high; triangular, spinach-shaped, indented leaves; and heads of flowers growing sparsely all along the sides of the stalk, succeeded by small, reddish, strawberry-fruit.

Varieties.] Dwarf Striped-leaved Strawberry-Spinach—Dwarf White Strawberry-Spinach.

All these species and varieties are hardy annuals, and rise in spring first with a few leaves, shooting up stalks in May or June, flower and ripen fruit in July, August, and September, and soon after perish.

They

They merit culture as plants of ornament, for the singular variety of their fruit, being the size of common wood-strawberries, and numerous on the stalks, make a fine appearance in July and August, but are not eatable.

They succeed in the common borders, and some planted in pots to adorn court-yards, in assemblage with other potted plants, have a pretty effect.

Their propagation is by seed annually in March or April, sown either in patches in the borders where they are to remain, or together in a bed of common earth, to be afterwards transplanted into the places where they are to flower, covering the seed about half an inch deep, and the plants will appear in a month, observing, if they are sown in patches, to leave only three in a patch, at five or six inches distance, and if sown in a bed for transplanting, they must be planted out before they begin to shoot up their stems, disposing them as above in different parts of the borders; and if any are to be potted, plant one in each pot, giving the whole occasional waterings.

When their stems are advanced, support each with a stick, otherwise the weight of the berries will bear them down to the ground.

BOCCONIA, Greater Tree Celandine.

There is but one species, a shrubby exotic of the stove, esteemed for the beauty of its large foliage.

Class and order, *Dodecandria Monogynia*.

Characters.] CALIX, two oval concave leaves. COROLLA, no petals. STAMINA, twelve short filaments, and long antheræ. PISTILLUM, a large, roundish, contracted germen, semi-bifid style, and single stigma. PERICARPIUM, an oval compressed fruit of one cell, full of pulp, and one seed.

The species is,

Bocconia Frutescens.

Shrubby Bocconia, from Jamaica.] Bocconia with an upright, strait, robust, branching stem, growing ten or twelve feet high, covered with a white bark; large, deeply-sinuated, glaucous leaves, ten or twelve inches long, half as broad, placed alternate; and flowers in loose spikes from the ends of the branches.

The whole plant abounds with a yellow acrid juice.

This plant is propagated by seeds from America, sowing them in spring in pots of light earth, and plunge them in a bark hot-bed; and when the plants come up, prick

them into separate pots, which must always be kept in the stove.

BOMBAX, the Silk Cotton-tree; so called from the fine silky down contained in the seed vessel.

There are three species, trees of extraordinary magnitude and lofty stature, natives of America, Asia, and Africa, where, modern writers affirm, they are so large, that sixteen men cannot fathom them, and so tall, that an arrow cannot reach their top, with heads so widely diffused (says Bosman in his Description of Guinea) that 20,000 men, closely armed, might easily stand under the branches.

They are retained in this country in hot-houses, as plants of singularity, and for the variety of their singular foliage; but there are little hopes of their ever flowering in England.

Class and order, *Monadelphia Polyandria*.

Characters.] CALIX is monophyllous, campanulate, quinquefid, and permanent. COROLLA is divided into five oval concave segments. STAMINA, many filaments united below, and incurved antheræ. PISTILLUM, a round germen, slender multiparted style, and round stigmas. PERRICARPIUM, a large, oblong, turbinate, ligneous, quinquivalvular capsule of five cells, full of a cottony down, inclosing many round seeds.

The species are,

¹BOMBAX *Ceiba*.

Ceiba, or Thorny Bombax.] Bombax with an upright strait trunk, closely armed with short strong spines, branches coming out near the top, adorned with leaves composed of five long spear-shaped lobes, connected at their base, and polyandrous flowers at the ends of the branches, succeeded by oval fruit larger than a swan's egg, filled with seeds and cotton.

²BOMBAX *Pentandrum*.

Pentandrous Smooth Bombax.] Bombax with an upright, strait, unarmed trunk, branching at top, garnished with leaves composed of nine long spear-shaped lobes, united at their base, and pentandrous flowers from the end of the branches, succeeded by large oval fruit full of seeds and cotton.

³BOMBAX *Heptaphyllum*.

Heptaphyllous Smooth Bombax.] Bombax with an upright, strait, unarmed trunk, branching near the top; heptaphyllous, or seven-lobed leaves, united at the base; and polyandrous flowers, succeeded by large oval fruit, containing seeds and cotton.

These

These trees being natives of both Indies, and other warm parts of the world, in this country must always reside in a hot-house.

They are raised from seeds procured in the capsules from the West Indies. Sow the seeds in spring in pots of light earth, and plunge them in a substantial hot-bed of dung or tan, where the plants will appear in three or four weeks, which are to be pricked into separate small pots, plunging them in the bark-bed, giving shade and water, and let them be constantly kept in the stove, shifting them occasionally into larger pots and fresh earth, watering them plentifully in summer, but moderately in winter.

BONTIA, Wild Olive of Barbadoes.

This genus comprizes one woody pyramidal evergreen of the stove, of ornamental appearance.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX**, a small quinquefid permanent cup. **COROLLA**, one ringent petal, with a long tube gaping above, the upper lip erect and emarginated, the under one trifid and revolute. **STAMINA**, four filaments, two longer than the others, and simple antheræ. **PISTILLUM**, an oval germen, simple style, and bifid stigma. **PERICARPIUM**, a large oval berry, including an oval nut.

The species is,

BONTIA Daphnoides] Bontia with a woody stem and branches, rising ten feet high; oblong, narrow, smooth, thickish leaves, crenated at the edges; and flowers from the sides of the branches, succeeded by large oval fruit, that sometimes ripen in England.

This plant is propagated easily by seeds in a hot-bed; also by cuttings, with the same assistance, and the plants must always remain in pots, and reside in the hot-house.

BORAGO, Borage.

Of this genus are two hardy herbaceous plants, cultivated in our gardens, an annual and a perennial, rising with stalks two feet high, simple leaves, and monopetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is five-parted at top, and permanent. **COROLLA**, a single rotated petal, with a short tube, spreading and five-parted above. **STAMINA**, five connivent filaments, and oblong connivent antheræ. **PISTILLUM**, four germina, slender style, and single stigma. **PERICARPIUM** none, the calix becomes swollen, and contains four roundish seeds.

The species are,

¹**BORAGO Officinalis**.

Common Annual Borage.] Borago with annual roots, large, oblong, rough leaves, spreading on the ground; rough branching flower-stalks two feet high, garnished with leaves placed alternate, and flowers from the sides and top of the stalk and branches.

Varieties.] Common Borage with blue flowers—with red flowers—with white flowers—with variegated leaves.

²**BORAGO Orientalis**,

Oriental, or Constantinople Perennial Borage.] Borago with fleshy spreading perennial roots, sending up large heart-shaped leaves, and stalks two feet high, dividing upward into footstalks, terminated by panicles of pale blue flowers.

The *Borago Officinalis* is the Common Annual Borage, an excellent pot-herb, and the young leaves and flowers are by many esteemed to eat as a salad and for cool tankards, and the flowers also for medicine.

The plants rise in spring, shoot up flower-stalks in May, June, and July, and continue flowering till autumn, when they perfect seeds, and then die.

They are propagated by seeds any time in spring, summer, or autumn, in any common soil, in the place where the plants are to remain, observing, when a constant succession of the plants are required, it is proper to make three different sowings from spring till autumn. Sow the seed broad-cast, and rake it in, and when the plants have leaves an inch broad, clean and thin them by hoe to six or eight inches distance.

If this plant is permitted to stand to ripen and scatter its seeds, there will be a supply of plants at almost all seasons of the year, which will continue rising every time of stirring the ground.

The Oriental Borage is a perennial, and chiefly esteemed as a flowering plant; it will prosper in any dry soil, and its propagation is either by seed, or dividing the roots in autumn.

BORDERS. In gardening, Borders are useful narrow compartments of ground, which divide and encompass the different principal divisions of a garden, and bound the walks.

Borders may be considered of two kinds, the useful and ornamental.

For useful purposes, one sort are those which are carried round the walls of a kitchen-garden,

garden, and are most useful, whereon to plant various sorts of dwarf fruit-trees, such as peaches, nectarines, apricots, &c. to be trained to the wall to form wall-trees; and such of those borders that are of a south aspect, are likewise extremely useful, whereon to raise various early esculent herbs, roots, and legumes; and those of the other aspects are proper for the raising and pricking out many sorts of plants in summer, that require some degree of shade at particular periods of growth.

These borders should be a yard at least wide, but if six or eight feet, the greater advantage it will be to the trees, &c.

Another sort of useful Borders are those which divide and surround the principal division of the kitchen-garden, and immediately verge the main walks, which are useful, whereon to plant ranges of dwarf apple, pear, plum, medlar, and cherry-trees, &c. to form an espalier (see *ESPALIER*); for which purpose the borders should be five feet broad, and the line of trees placed four feet from the outer edge thereof, so that there will be a four feet Border without, and a foot wide one within the espalier, both of which will be useful in the culture of many small esculent plants.

Borders in pleasure-grounds are to be considered as of the ornamental kind.

In this district formerly Borders were very predominant; almost every walk was bounded on each side by a Border, embellished with various ornamental plants: this taste however is now almost supplanted; but a grand walk, ornamented on each side with a spacious border full of curious flowering plants, makes a noble appearance.

Likewise Borders for flowers, carried round the boundary of lawns near the habitation, have also an agreeable effect.

In the ancient taste of parterre-works Borders greatly prevailed, the parterres being principally formed of numerous narrow Borders, with intervening alleys of the finest turf, gravel, shells, or sand, the parterre being first bounded by regular borders, and within which were carried on the various geometrical works in many curious devices, but which is now banished our gardens, like all other works of regularity: for the sake of variety, some works of this nature might still be admitted, particularly in the Chinese taste. See *PARTERRES*.

Borders for particular curious flowers, such

as the curious sorts of hyacinths, tulips, ranunculas, anemones, carnations, &c. may be made either along the sides of walks, or detached.

The proper breadth of Flower-borders is, that, if intended chiefly for small plants, or for the different sorts of bulbous-rooted flowers, they should be four feet wide; but if designed for all sorts promiscuously, they ought to be six or eight feet in breadth.

Borders that immediately verge gravel or sand-walks, should be planted with edgings of dwarf evergreen plants; several sorts are used, such as box, thurst, pinks, &c. but the former is the neatest and most durable edging yet known. See *BUXUS*.

The Borders should always be raised two or three inches above the common level, and finished off with a gentle swell or rounding.

BOSEA, *Yerva-Mora*, or Shrubby Golden-rod.

This genus furnishes but one species, an exotic shrub of the green-house.

Class and order, *Pentandria Digynia*.

Characters.] *CALIX* is five roundish concave leaves. *COROLLA*, no petals. *STAMINA*, five filaments and simple antheræ. *PISTILLUM*, an oval oblong germen, no style, but two stigmas. *PERICARPIUM*, a globular berry, having one seed.

The species is,

BOSEA Yerva-Mora.

Yerva-Mora, or *Golden-rod-tree*.] *Bosea* with a strong woody stem, dividing irregularly into branches, grows eight or ten feet high, garnished with long leaves, whitish underneath, with purple veins, and purple flowers in clusters from the ends of the branches.

It is an exotic from the Canary islands, and is retained here, to add to the collection of the green-house.

Its propagation is by cuttings planted in pots in spring; and, if plunged in a hot-bed, will more quickly emit roots, though they often effect it without that aid.

BOSQUETS are clumps, or detached compartments of ornamental trees, shrubs, and plants, disposed either in a regular or irregular form, to embellish gardens, parks, &c.

These compartments have a very ornamental effect in gardens, and are composed of a great variety of deciduous and evergreen trees, and herbaceous perennials of tall growth. Their dimensions should be proportioned to the extent of the ground, even from ten to a hundred feet, or more, in width, though the

size and form should be varied in different exposures; and as to figure, some may be planned in different regular forms, others in several different irregular figures, to effect the greater diversity; but in ancient designs, they were generally all disposed in regular squares, angles, circles, octagons, &c. and commonly each separate Bosquet was bounded by regular hedges, kept low, and in exact order, by an annual shearing, having grand entrances formed into porticos, and other architectural devices; and within the hedges of the large compartments, walks of grass, gravel, or sand, were often carried round, and between the trees; but I should not advise any general work of surrounding these compartments with hedges, for the trees and other plants will appear to greater advantage in open rural clumps, although, for the sake of variety, a regular Bosquet, surrounded as above, might be here and there admitted in spacious gardens; but the hedges should not be permitted to be more than four feet high, and may be either of evergreen, or deciduous plants: of evergreens, such as yews, holly, laurustinus, laurel, alaternus, phillyrea, evergreen-oak, tree-box, bay; and of deciduous kinds, hornbeam, beech, elm, lime, alder; all of which should be neatly sheared annually, and kept so low that the trees and plants within may be easily seen from the outer walks, lawns, &c. See HEDGES.

The disposition of these compartments, both of the regular and irregular designs, should be so varied as to produce the greatest diversity; some placed towards the boundaries of grand lawns and spacious opens, others in forming shrubberies, wilderness-works, &c. and some natural clumps may be stationed on the boundaries of rural avenues; also distributed in different parts of parks.

In planting and embellishing these compartments, great variety of shrubs and trees should be employed, both evergreen and deciduous, of different magnitudes, shades, and times of flowering, and particular care is necessary to dispose the trees and shrubs according to their several growths and statures, so as they rise gradually one above another from the sides to the middle, and at such proportionable distances, that there may be full scope for the rural diffusion of branches, so as each sort may display its spreading head according to its natural growth.

It is most adviseable to plant the deciduous plants and evergreens in separate clumps, though a few dwarf evergreens may be distributed in

the fronts of the deciduous compartments; and in the clumps of both sorts may be planted also, towards the sides, various kinds of tall perennials, and near the edges low plants of primroses, polyanthus, violets, daffodils, &c.

All the culture necessary to the various plants in these compartments, is to cut out any dead wood, and retrench or shorten very irregular branches, just to preserve them within moderate bounds, and each sort distinct; and the ground between the plants to be annually dug, especially in small Bosquets, and hoed two or three times in summer to destroy weeds.

BOWLING GREEN, a spacious level grass-plot in pleasure-grounds, designed both for ornament, and the recreation of bowling in summer.

This compartment is generally planned near the habitation, contiguous to the back or side-fronts, sometimes serving also by way of a lawn to that part; or it may be stationed at the termination of a grand walk or avenue of moderate extent, for it should not be far from the house; or it might be contrived amidst any contiguous detached plantation, or wilderness-work, serving also by way of a grand opening to such places, and should at any rate have the advantage of the shade of tall trees, so stationed on the boundary as to afford shade, which, at least, should be pretty considerable in an afternoon, as that being the time of day company usually walk out to the diversion of bowling.

As to the dimensions, that where there is scope of ground, should not be less than an acre; and as to figure, the most common is that of an exact square; but some are also oblong, others are circular, though, to suit the general plan or figure of the ground, it may be contrived either of a regular form, or any well-calculated irregular design, when consistent with the other works of the garden; and its boundaries may be a spacious border, either strait or serpentine, embellished with the choicest shrubs and flowers, although, in the ancient regular works, the boundary was very commonly a regular grass-slope of two or three feet perpendicular height, sometimes forming a sort of terrass round, with a gravel-walk at top.

The plane or surface of the Green should be of a horizontal level, and as high at least as the general level of the adjoining ground, so as to preserve it always free from standing water.

It should be levelled in an exact manner, and layed with the finest grass-turf that can be procured from a close-pastured common or downs. See TURF.

The dimensions should be set out with stakes placed round the extremity fifteen feet asunder, then take the determined level by five stakes, that is, one in the middle levelled to the determined height, and according to this, level in four more, one on each side of the ground, as directed under the article LEVELLING, so that there will be five stakes in two lines set in a true level; then place stakes in rows cross-ways at fifteen feet distance, to form the ground into pannels, for the greater convenience of levelling it to truth, observing to level in these according to the above five stakes; and when this is done, proceed by line and spade to form the ground, by making up lines firmly from stake to stake according to the mark of level, and so make up and rake the pannels according to the lines, working every part equally firm, that it may not hereafter sink into hollows; and if the surface has two or three inches depth of light, sandy, or any poor dry earth, it will render the grass finer.

The turf for laying the Green is to be cut in the usual way a foot wide, a yard long, and an inch thick, which must be laid with the greatest exactness, well-beating and rolling it repeatedly, as directed under the article GRASS.

To keep the Green in perfect order, it must be constantly poled and rolled once or twice a week, or oftener, as you shall see it necessary; for as often as worm-casts appear it must be poled, to scatter them about, then directly rolled with a wooden roller, to which the scattered worm-casts readily adhere, whereby the surface is rendered clean; it must also be frequently rolled with a heavy roller, to preserve a firm and even surface; mowing must also be duly performed in the proper season once a week at least, but if much played upon, it will require mowing two or three times a week at some particular times, especially where the grass abounds with common wild daisies.

All weeds that appear should be carefully picked out, otherwise they will encrease, and greatly deface the grass.

BRACTEA, a Floral Leaf, the botanic term for such leaves that are attendant on the flower, coming out with it on the same stalk, differing in size, shape, and colour, from the other leaves of the plant, and are often situated

so near the flower as to be sometimes mistaken for the calix.

BRACTEA is also one of the seven fulcra, or props of plants. See FULCRA.

BRASSICA, the Cabbage, Cauliflower, Broccoli, &c.

This genus is very comprehensive in useful esculents of the kitchen-garden; it includes not only the numerous tribe of cabbages, favoys, borecole, and coleworts, but also the cauliflower, and all the varieties of broccoli, and, according to Linnæus, also the turnep; but to render every thing as intelligible as possible for practice in their cultivation, we shall treat of each article in a separate division, under the generic head Brassica.

Class and order, *Tetradynamia Siliquosa*.

Characters.] CALIX, four spear-shaped, concave, deciduous leaves. COROLLA, four oval plane petals placed cross-ways. STAMINA, four long, and two short filaments, and erect pointed antheræ. PISTILLUM, a taper germen, short style, and headed stigma. PERICARPIUM, a long depressed pod of two cells, filled with round seeds.

Modern botanists contend, that there is only one real species of cabbage, and that the original species is the wild perennial sea-cabbage, and the parent of all the different cultivated varieties of cabbage, favoys, borecole, coleworts, turnep-cabbage, cauliflower, and broccoli. Whatever the five former sorts may be, the cauliflower is apparently a distinct species of the same genus, and the broccoli is most probably a variety of the cauliflower.

The original species, according to modern botanists, is,

BRASSICA *Sylvestris*.

Wild Perennial Sea-Cabbage.] Brassica with a perennial root and stalk, the stalk dividing into many perennial branches, garnished with cut leaves, placed alternate, and a cluster of leaves, terminating all the shoots and branches.

It grows wild on Dover-Cliffs and other sea-coasts, and if required in gardens for curiosity, it may be raised from seed like other cabbages.

From this wild cabbage, say modern botanists, were obtained all the following cultivated varieties of our gardens.

¹BRASSICA *Capitata*, Common Heading Cabbage, including a large train of varieties.

²BRASSICA *Capitata Sabada*, Savoy Cabbage, or Savoy, including varieties.

³BRASSICA *Fimbriata*, Fringed Cole, or Borecole,

Borecole, including Scotch-Cole, and most other varieties of open Colewort.

⁴*BRASSICA Caulo-rapa*, Turnep-Cabbage.

⁵*BRASSICA Cauliflora*, the Cauliflower.

⁶*BRASSICA Broccoli*, the Broccoli, including varieties.

The following is undoubtedly a distinct species, which although, in its general habit, is apparently a very different plant from the cabbage-kind, yet the characters of its flowers being the same, Linnæus ranges it as a species of *Brassica*.

⁷*BRASSICA Rapa*, RAPA, or the Turnep.

As the above articles are commonly considered as different plants among gardeners, and mostly requiring different culture, we shall treat of them, and their respective varieties, under separate heads; and first of the Common Cabbage.

First Division.

¹*BRASSICA Capitata*, Common Heading Cabbage, and varieties.

The varieties of this sort are numerous, and are all denominated Cabbages, from the circumstance of their inner leaves turning in closely one over another, till by degrees they form a large, compact, globular, or oval head, some varieties of which obtain an enormous magnitude, and sometimes weigh fifty or sixty pounds.

As some varieties are in perfection in summer, others late in autumn, they are divided into different classes, viz. 1. Summer Cabbages, 2. Autumn Cabbages.

The Summer Cabbages are,

¹*Early Summer Cabbage.*] *Varieties*, Small roundish early Cabbage—Larger oblong early Cabbage.—The first sort comes early in May, the second about the middle, or towards the latter-end; both of which soon become very hard and crack, so there should not be any considerable quantity raised for private service.

²*Sugar-loaf Cabbage.*] *Varieties*, Early Dwarf Sugar-loaf Cabbage—Large Hollow Sugar-loaf Cabbage.—The first is a small, longish, pyramidal Cabbage, comes early in June, and is very sweet while young, but soon grows hard; the second is a fine, large, pyramidal, hollow Cabbage, comes the end of June, and is in fine perfection in July and August, seldom grows hard or cracks, and is a fine family or marketable Cabbage.

³*Russia Cabbage.*] A small roundish Cabbage, comes in July, heads very fast, and soon grows hard; but if used while young and hollow is very sweet and tender.

The following are autumn and winter cabbages.

⁴*Common Round White Cabbage.*] A middle-size, roundish, very white Cabbage; is in perfection in August and September, gradually acquires a degree of hardness, and is hardy to endure the winter.

⁵*Long-sided Cabbage.*] A large, long, somewhat hollow Cabbage, comes in for use in September, and continues excellent all October and November, and seldom grows very hard.

⁶*Hollow Cabbage.*] A very large oval hollow Cabbage, never grows hard, is exceeding sweet and tender eating, and is in high perfection in September and October.

⁷*Flat-top'd Cabbage.*] A very large spreading Cabbage, generally cabbaging very broad, and flat at top, and pretty close and firm, is in perfection in September, and will continue till Christmas.

⁸*Musk Cabbage.*] A middle-size, roundish, hollow, very tender, crisp-eating Cabbage, of a musky scent; is in perfection from September till Christmas.

⁹*Giant, or Great Scotch Cabbage.*] An admirable, large, roundish Cabbage, heading very close and hard, arrives to perfection in September and October, and will continue all winter; valued principally as a Field-cabbage for feeding cattle.

¹⁰*Red Cabbage.*] A middle-size, roundish, thick-leaved Cabbage, heading very hard, the whole as red as blood, and the darker the red, and the more thick and fleshy the leaves, without any white in the ribs and veins, the more valuable; is in perfection from autumn until the end of winter, esteemed chiefly as a choice pickle, also to shred raw to eat as a salad.

All these varieties of Cabbage are of the biennial tribe, being raised and attain perfection one year, the next they shoot up into stalk for flower and seed, and soon after totally perish.

They are all raised from seed annually in beds of common earth, from which they must be transplanted; the time for sowing is autumn and spring; those raised in autumn arrive to perfection early the following summer and autumn, and the spring-sowings cabbage the same year, but not till autumn and beginning of winter, and seldom in such perfection as the autumn-raised plants. See their Culture.

Culture of the Summer Kinds.

The early Summer Cabbage, the Sugar-loaf Cabbage, and Russia Cabbage, are generally cultivated for summer service, and may

may either be sown in spring or autumn; but by raising the plants in autumn, i. e. August, they arrive to perfection early the following summer, that is, some of which are planted out in October or November, the others in the spring; the early kinds attain perfection in May, which will be succeeded by the Sugar-loaf and Russia Cabbage in June and July, furnishing a supply till autumn, when these will be succeeded by the spring-raised plants, either of the same, or large late sorts; but the large Sugar-loaf Cabbage is what I should chuse to cultivate principally for the general summer crop, particularly for supply of a family, being the finest eating Cabbage, and continues the longest in perfection; though for market-use they often raise a larger quantity of those that take up the least room, and come in and out the soonest; for the early kinds cabbage very fast, soon grow hard, and do not continue good above a month.

Therefore, in order to raise an early and general summer crop of any, or all of these sorts, let some good fresh seed be procured for sowing the first or second week in August; mark the time, for if sown earlier, the plants are apt to fly up to seed in spring, and if sowed much later, they will not acquire due strength before winter.

At that time prepare a spot of rich ground in an open exposure, digging it neatly one spade deep, and divide it into one or more four feet wide beds; directly sow the seed, each sort separate, and immediately tread and rake it in. If the season proves showery, the plants will rise in ten or twelve days; but if dry weather prevails, it is necessary to water the beds frequently both before and after the plants appear, and keep them clean from weeds.

About the middle of September, or when the plants have leaves an inch or two broad, it is proper to prick out a quantity of the largest from the seed-bed into nursery-beds, to acquire due strength previous to their being planted out for good in October and spring. For this purpose of pricking out, dig an open spot of the best ground, divide it into four feet wide beds, and rake the surface smooth; here prick the plants in rows six inches distance, and three or four inches apart in the lines, giving directly a hearty watering, which, if dry weather succeed, should be repeated occasionally.

Here they are to remain, some till October or November, and the principal part till Fe-

bruary or March, at each of which times a quantity of the stoutest plants are to be transplanted for good into the places where they are finally to remain to cabbage; good ground in an open exposure must be allowed them, and if this is well dunged, it will be a particular advantage to the crop, digging in the dung one spade deep; then by line and dibble proceed to put in the plants in rows, the small early kinds two feet row from row, and about the same distance in the lines; but the large Sugar-loaf kinds should be set two feet and half distance every way, and a double quantity of these sorts should also be planted, if for the service of a family, for the early kinds seldom continue long before they grow hard. Those of each sort that are planted in autumn will come in for use the earliest; and the spring plantation will succeed them regularly. Observe that, as the autumn plantation sometimes suffers by the severity of frost, or other causes, in winter, when this is the case, the deficiencies must be made good occasionally from those in the nursery-beds.

Those plants that have remained in the nursery-beds all winter, should be planted out finally in February, though, if they are much cut by the winter's frost, it is proper to let them remain until March or April to recover, planting them as above directed.

When the winter happens to prove so severe as to cut off most of the autumn-raised plants, recourse must be had to an early spring sowing in February, or early in March, but the sooner the better.

But where a constant succession of perfectly young Cabbages are required to be continued through the summer and autumn seasons, it is eligible to perform a spring and summer sowing, to succeed those of the autumn raising; therefore sow some of the Sugar-loaf kind in February or March, and more about the middle of May, managing them as already directed, which will furnish a supply of young Cabbages from August till December.

All the culture these crops require after being finally planted out, is to hoe the ground occasionally between them in dry weather, to destroy weeds, and when the plants have advanced a little in growth, to draw some earth once or twice about the bottom of their stems, which will strengthen the plants, and forward them considerably, that probably the earliest sorts will make an effort for heading early in May, when, if you are anxious to have them as forward as possible, some of the best

best may be assisted, by tying their leaves regular together with an osier-twigg, or piece of bass, which will blanch them internally, make them crisp and ready for the table eight or ten days sooner. When the early kinds are cut for use, permit the stalks to remain to produce a crop of sprouts, which they will effect abundantly; and these may either be gathered while young and green, or some might stand to form little heads, either of which are in many families preferred to any other summer greens; for which purpose, therefore, of yielding sprouts, a quantity of the Sugar-loaf Cabbage-stalks should be particularly left all summer and autumn.

Culture of the Autumn Kinds.

As already noticed, the autumn and winter Cabbages are, the Common Round White Cabbage—Long-sided Cabbage—Hollow Cabbage—Flat-topped Cabbage—Musk Cabbage—Giant or Scotch Cabbage—and the Red Cabbage.

These sorts are adapted principally for autumn and winter use, as they rarely attain tolerable perfection before August, and some of the larger kinds not till September and October, and continue in excellent condition till Christmas, or sometimes till the end of winter, some of which arrive at an enormous bulk, and if used while young, that is before they grow hard, are excellent eating.

The season for sowing all these late kinds is either in autumn or spring, but to have a large succession, it is proper to sow some at both seasons; those sowed in autumn, i. e. the first week in August, arrive at perfection betimes the following Autumn, that is, August and September; and the spring sowing come in about Michaelmas, though they seldom attain any tolerable perfection till the end of October, and are very fine in November and December, but rarely obtain so large a growth as the autumn raised plants.

As before observed, the autumn sowing is to be performed in the beginning of August, and the spring sowing in March, or early in April.

The same method of sowing the seed, and pricking out the plants, is to be observed, as directed for the summer kinds; and the time for transplanting them finally is, for the autumn-raised plants, a few in October, but the principal part in February, or early in March, and the spring-raised plants will be ready to plant out in May or June; all of which must

have an open exposure, well-dunged ground, and the plants set in rows two feet and half at least distance; but for the larger kinds, a yard distance each way should be allowed. All the culture they need is hoeing, to extirpate weeds, and drawing earth about their stems, which is an essential piece of culture to all the Cabbage kind.

The Red Cabbage is valued principally for pickling and stewing, and is in perfection in autumn and winter; it requires exactly the same culture as the former sorts. The seed may be sown in autumn or spring, though, as being a late Cabbage, the spring-raised plants rarely attain any tolerable size, therefore it is proper to sow the main crop early in August, and the plants will be fit to prick out in September or October in nursery-beds, to remain till February or March; then plant them out finally into an open situation, where they will arrive at due perfection about Michaelmas, and continue several months.

Cabbage Coleworts.

Cabbage Coleworts are now almost universally substituted in lieu of the common open green Colewort, which, though of estimation on account of its hardiness, in being proof against frost, yet, as table-greens, are apt to be tough and rank-tasted, and greatly inferior to the former. What was originally understood by Coleworts, is such Cabbage-greens that never close or cabbage, but always remain quite open and green to the heart, so were formerly raised in autumn and winter as open greens; and that by using Cabbage-plants as such while they continue open and green, are now denominated coleworts, which are the most excellently sweet and tender greens that can be cultivated for autumn and winter eating, and continue exceeding fine all the spring, and supply the table till the arrival of summer Cabbages; so that for supply of a family, a considerable quantity should always be raised every autumn.

Any sort of white Cabbages may be sown for this purpose of Coleworts, though the Sugar-loaf kind surpasses all the other sorts for delicacy of eating.

The proper time for sowing the seed of either kind, for the purpose of Coleworts, is any time in July, for the autumn and winter crop; but to have them continued without running for spring drawing, some seed should also be sowed the beginning or middle of August, as observed of the Cabbages.

They

They are to be sown in an open spot, and raked in, and when the plants have leaves two or three inches broad, transplant them where they are finally to stand, in rows a foot asunder, and half that distance in the rows; all the culture they require is to have the ground hoed, to kill weeds, and loosen it about the plants; and when their leaves are as large as a man's hand, or thereabout, they are of due size to begin to draw as Coleworts.

In drawing the Coleworts for use, especially the spring crop, where there is a large quantity, some draw every other row, permitting the intermediate ones to stand to cabbage, so cutting for use also every other one in the remaining rows, according as they form little hearts, leaving the others to cabbage more perfectly.

Saving Cabbage-Seed.

The common method to save Cabbage-seed, is to plant some of the full-grown Cabbages in autumn or beginning of winter in a dry spot, trenching them in down to their heads at two feet distance each way; or otherwise, either let a quantity of the stalks, after the heads have been cut occasionally for use, remain, or transplant them to a convenient spot, to produce seed from their sprouts, which answers the same purpose, but in this case no sprouts must be gathered from these stalks; or instead of either of these methods, particularly to the summer Cabbages, you may slip a quantity of the forwardest sprouts from the stalks in June, July, or early in August, in moist weather, and plant them twelve or fifteen inches distance, giving occasional watering, they will readily take root.

In either of the above methods, the plants will all shoot up to stalk the following spring, flower in June, and perfect seeds in July or August.

It is necessary here to remark, that, in order to preserve the respective varieties genuine, the most perfect of each sort should be marked when in full perfection, for without this precaution they will degenerate. Another thing of importance is, that if it is intended to save seed from more than one sort, the different varieties should be planted as far distant from one another as the extent of the garden will admit, to prevent as much as possible the communication of the farina of the different sorts, which would fecundate each other, and the effect would be productive of a mongrel breed.

When the seed begins to ripen, watch the

birds, which will attack it voraciously from every quarter.

As soon as it is fully ripe, which is very discoverable, cut the stalks off near the bottom, and after being exposed a few days in the sun to dry, let the seed be threshed out upon cloaths, or a close even floor, and spread it in a dry airy place a day or two to harden, then put it up in bags.

Second Division.

²BRASSICA *Saubada*, the Savoy-Cabbage, or Savoy.

The Savoy is a variety of the Cabbage, though with care it will always retain its difference from seed; it admits of some varieties, all of which have finely curled leaves, and they head or cabbage to a large size, which are fine eating from August till March.

The varieties are] Common Green Savoy—Large Green Dutch Savoy—Yellow Savoy.

These varieties are excellent for autumn and winter service; they cabbage to fine handsome heads, which never grow hard nor crack, greatly excelling any other sort of headed Cabbages for winter eating; and as they endure the frost better, they are most profitable both for family use and the supply of markets during winter.

They are propagated by seeds sown at two or three different times, that is, if intended to have Savoys as early as possible, it is proper to perform the first sowing in August, as directed for the common Cabbages, or early in February, and another sowing in March, and a third about the middle of April, by which practice you will have a fine succession of large heads from about the middle of August to the end of winter; those of the autumn-raised plants will be exceeding large, and in fine order for eating part of August, all September and October, which will be succeeded by the others in October and November, and which will continue through the winter, and part of the spring, till they run up for seed.

Each sowing should be in an open spot, and raked in, and when the plants have leaves an inch or two broad, and that, if they stand thick in the seed bed, it is proper to prick out a quantity of them three or four inches distance, to acquire strength against the time for planting them out finally. Some of the autumn-raised plants may be planted out for good in October or November, or any time in winter, or beginning of spring; and the spring-raised plants are to be planted out occasionally as ground is cleared, any time in May.

May, June, July, and August; those planted out early should be set two feet and half distance every way, and the next crop about two feet; but the latter plantations need not be planted more than a foot and half distance; all of which plantations should be in open exposures, the farther from trees, hedges, buildings, and the corners of gardens, the better, as the less liable they will be to the depredations of caterpillars, as is the case frequently with those in close situations.

It is customary to plant out the summer plantations of these plants between rows of forward beans, peas, kidney-beans, cauliflower, early cabbage, and other crops that stand distant in rows, and are soon to come off the ground; by this practice some time is gained, though the plants are generally finest in the end, when they are planted in a clear spot of ground, previously dug for their reception.

In performing the summer plantations, it is of much advantage to chuse moist weather for that work, otherwise watering must be practised several times till the plants strike root.

All the culture they require, is to be hoed to kill weeds, and draw a little earth up to their stems.

To save Savoy-feed you may either plant down a quantity of the best sorts in winter, or beginning of spring, or permit the stalks to stand, or transplant them to a convenient place to produce seed from their sprouts, as observed of the common cabbage, which see.

Third Division.

³BRASSICA *Fimbriata*, Fringed Cabbage, or Borecole, Scotch-Cole, and Common Coleworts.

The Borecole, and the other plants of this class, are all varieties of Cabbage of the open kind, or such that never close to form a head or cabbage, but always remain quite open and loose to the heart, all of which possess such a degree of hardness, as to bid defiance to the severest winter weather; so a few of them merits culture, to stand as reserve in case of a severe winter cutting off the other greens.

The varieties of Borecole are] Green Curled Borecole—Red Curled Borecole—Thick-leaved Curled Borecole—Finely-fringed Borecole.

All these varieties of Borecole generally rise with thick stalks a yard or more high,

surmounted by a large head of thick leaves, spreading horizontally every way, which are finely fringed, and curled in a curious manner; and in the spring the sides of the stalks are closely adorned from bottom to top with fine sprouts, which, as well as the principal head, boil exceeding green, sweet, and tender; and as they are extremely hardy, I should advise, for the service of a family, to cultivate a due quantity every year, to stand till towards spring, by way of reserve, in case of a severe winter.

They are raised from seeds sown in March, or beginning of April, in an open bed of good earth; the plants will rise in a fortnight, or less time, a quantity of which should in April, or beginning of May, be pricked out four or five inches asunder, to remain six weeks; then plant them out finally into a fully open exposure, in rows two feet distance.

Those raised in March, and planted out early in summer, will advance with fine tall stems and large heads, and the advantage of their high stems is, they furnish the greater supply of sprouts, which come out closely on every side from the very bottom to the top.

To have good seed, mark some of the finest sorts in winter, and let them remain entire; they will run up in the spring, and ripen plenty of seeds in autumn.

Scotch-Cole, or Kale.

The Scotch Cole is also an open Colewort, and sort of brown Borecole, but some sorts have more robust stems, larger heads, with large, broad, curly leaves, in some standing erect, sometimes contracting themselves a little inward, but never cabbage. Of this sort, however, there are several varieties, some red, some green, &c. and are fine eating in winter, requiring the same culture as the Borecole.

Of this kind are perennial varieties, with variegated leaves, preserved in gardens as plants of ornament.

There are likewise perennial shrubby kinds of this sort, rising with tall branchy stems, adorned all the year with leaves, which in some sorts are finely variegated, and are of many years duration; those of them having variegated leaves make a pretty appearance.

All the sorts are raised from seed; but the variegated kinds are continued by planting slips of them in spring.

Common Green Colewort.

This is a hardy, open, green plant, hath large plane leaves, generally always green, will

will grow large, but never contracts, or forms any head, like a cabbage, is a very hardy plant, and was formerly cultivated in every garden for winter greens, and is the original garden Colewort; but till severely pinched by frost, it is tough and rank-tasted, and, at any rate, never boils so fine and tender as the Cabbage Colewort, for which reason it is rarely cultivated now for table, except by the farming gardeners, who raise large quantities in fields for the supply of markets.

On account, however, of its hardiness, it merits culture to stand till towards the end of winter, as a substitute, if the Cabbage Coleworts are cut off; in which case it may prove a necessary plant.

They are raised, for winter use, by sowing the seed in July, as directed for Cabbage Coleworts, which see.

This sort is frequently cultivated in fields for the feeding milch-cows in spring, for which purpose the cow-farmers about London used to raise vast quantities, sowing the seed in July, and is sometimes sown where the plants are to remain, so hoeing them out to six or eight inches distance; but as the ground is sometimes not cleared from other crops by the time the seed should be sown, it is then sown thick in the corner or side of a field, and the plants are afterwards transplanted.

Fourth Division.

⁴BRASSICA *Caulo-rapa*, Turnep-Cabbage.

This is a singular variety of Cabbage, having its stalk swelled globularly like a great turnep, and is crowned by a large tuft of leaves, which never close or cabbage.

There are two varieties.] Turnep-Cabbage, with the turnep above-ground—Turnep-Cabbage, with the turnep under-ground.

The plants rise and grow for some time like common cabbage-plants, after which the stalk of the first sort begins to swell at bottom, and continues swelling upward, till by degrees the whole is swelled like a very large turnep, which, in the second sort, is almost wholly within the ground; both sorts are crowned by a cluster of open leaves, and they are sometimes used as esculents.

It is the globular or turnep-part of the plant that is used, being sometimes sliced in soups, and by some used as common turneps; but unless used when quite young, are intolerably rank and unpalatable, so are principally admitted in gardens as curiosities.

They are however recommended for culture in fields for feeding cattle, particularly sheep; their chief merit is their hardiness, as they will survive the hardest winter.

They are propagated by seeds, sown annually in March or beginning of April, and the plants are in May, or early in June, to be transplanted into an open spot, in rows two feet asunder, keeping them clean from weeds, and draw a little earth about the bottom of the stem, and the turnep-part will be fully grown by Michaelmas, and continue all winter.

Or they may be sown where the plants are to remain, and hoed out to a proper distance.

Fifth Division.

⁵BRASSICA *Cauliflora*, *Cauliflora*, or the Cauliflower.

The Cauliflower, as we formerly observed, is supposed to be a variety, accidentally obtained from the seed of some of the sorts of common cabbage, and brought to its present improved state by the effect of diligent culture, which improvement was first of all obtained in the island Cyprus, from whence the seeds were introduced into the different countries of Europe; and our British gardens now boast the superiority, by exhibiting the plants in greater perfection than most parts of the world.

There is however an apparent specific difference betwixt the common *Brassica* and the Cauliflower, both in their general growth and eatable parts; the cabbage hath broad, roundish, thick leaves, and when it shoots up stalks for flower and seed, rises with only one main flower-stem immediately from the head, though it divides upward into many branches. In the *Cauliflora* the leaves are long, narrow, erect, and pointed, and when it shoots, rises with many stems, each of which also divide into many branches. It is the leaves of the cabbage only that are used; but of the Cauliflower, the ends or buds of the flower stalks; for the large, white, curdly head, in the centre of the plant, is only a compact collection of numerous buds, or ends of shoots, growing so closely together in a great round cluster as to assume the appearance of one compact head, but which, as just observed, being composed entirely of the ends of numerous advancing shoots or flower-buds, they, after a certain period of growth, divide, and run up into stalks the same year for flower and seed; but while they remain compact and undivided as above, they are in perfection for eating.

The Botanic Title and Description.

BRASSICA *Cauliflora*.

The Cauliflora, or Cauliflower.] Brassica with many

many branching flower-stems, rising immediately from the head of the stalk.

Varieties are] Early Cauliflower—Late Cauliflower.

In respect to these two varieties, they are alike in their growth and size, only the early kind will come in about a week before the other, provided the true sort can be obtained, of which however there is no depending, unless you save the seed yourself from the earliest sorts, as is the practice of the London kitchen-gardeners, who are always in possession of an early and later kind, of the former of which they are very choice.

Both the varieties are of a delicate temperature, being, for the general part, too tender to resist the cold of our winter without the aid of occasional shelter of glasses, &c.

Their General Culture.

The principal season of Cauliflower is May, June, July, and August; however, by performing three or four different sowings and transplantations, they may be obtained from May until near Christmas.

The curious in Cauliflowers generally have three or four different crops annually, i. e. the early summer crop—main summer crop—late summer crop—and the autumn or Michaelmas crop.

The seasons for sowing the above different crops are,

1. The early and main summer crop is sown about the twentieth of August, and the plants rising the same season, are to be pricked out and preserved through the winter under bell or hand-glasses, frames, or in warm borders, &c. as hereafter directed, which being transplanted in spring, arrive at perfection the ensuing summer, some in May, but the principal crop in June and July, and some continue in succession until August.

2. The late summer crop, to succeed the above, is sown in February, or early in March, and planted out in May, as hereafter ordered, which come in for use in August and September, though they will be inferior to the former crop in size and beauty.

3. To have a Michaelmas or autumn crop, another sowing is performed about the 24th of May, which being planted out in July, come in after Michaelmas, arriving to perfection gradually in October, November, and part of December; but the Cauliflowers of this crop are never so large, fair, nor perfectly headed as the summer crops; but as

they are always acceptable, it is necessary to have them, and the London gardeners always raise great crops at that season, which they commonly call Michaelmas Cauliflowers.

But we shall proceed to treat separately of the culture of each of the above crops.

First of the early and main summer crop.

As above hinted, the early and main summer crops are obtained from plants raised in autumn, and preserved through winter under bell or hand-glasses, garden-frames, or in warm borders. The time for sowing is, as before observed, some time between the 20th and 24th of August, though the London gardeners are punctual to the 21st day; for as they cultivate large quantities, have by long experience found that to be the most successful period for sowing this crop, which, if sowed sooner in autumn, many of the plants are apt to button, as they term it, in winter, or early in spring, that is, they run to flower in their infant state, forming heads in the centre not larger than round buttons, so become useless; and if sown much later, they will not acquire due strength before winter, nor attain due perfection at the proper season; mark therefore the time of sowing, as above.

Great attention is necessary to procure good seed, such that is not more than one year old, and that have been saved from the prime sorts.

At the proper time, therefore, prepare a bed of the richest light earth in the full ground in a free exposure, by digging it neatly one spade deep, and break the surface fine; then, directly, either sow the seed on the surface, and rake it in even and lightly, or may first rake the surface smooth; then sow the seed, and sift light earth over it a quarter of an inch thick, or, after raking the surface smooth, may, with the back of the rake, shove the earth from off the surface equally, near half an inch deep into the alley, and then sow the seed; then, with the teeth of the rake, draw the earth back again over the bed with a kind of jerk, to make it spread evenly in every part over the seed, and then with the rake lightly trim the surface smooth. Some advise sowing this seed particularly upon old cucumber or melon-beds; there is no merit in this practice, since the seed will certainly grow better in a bed of good, rich, moist earth, in the full ground, than in the exhausted mould of an old hot-bed.

If the weather proves dry, gentle waterings in an evening is necessary, which is eligible

eligible both before and after the plants appear.

The plants generally appear in a week or ten days; all the culture necessary is occasional water and weeding until the latter end of September, when their leaves will be an inch or two broad; then it is proper to prick out a quantity of the best plants, in four feet wide beds of rich earth, in rows three or four inches distance, rejecting all crooked and black-shanked plants, and, as soon as planted, give a moderate watering, which, if dry weather prevails, must be moderately repeated; here let them remain until the end of October, or beginning of November, then must be transplanted into their winter quarters, some to be planted out finally under hand or bell-glasses for the earliest crop, see *HAND-GLASSES*; others into garden-frames, to be occasionally shielded with glasses till spring, then planted out; or, in default of frames, some may be planted close under a south wall, where they will often survive the winter tolerably well.

With respect to the earliest crop under hand or bell-glasses, as just mentioned, the following is their culture. In the end of October, or beginning of November, as above hinted, select a plat of the richest ground in one of the best-defended quarters of the kitchen-ground; this should be well dunged with that of old cucumber or melon-beds, and the whole then regularly trenched one good spade deep, burying the dung equally, then divide the ground into beds a yard wide, with foot-wide alleys between bed and bed, for the convenience of going in to raise, and set off and on the glasses, &c. this done, proceed to put in the plants, allowing three to each glass, though the London gardeners generally plant five, but if they all survive the winter, two of the best is enough to be left to come to perfection; however, at the time of planting them under the glasses, select for that purpose a quantity of the handsomest, strait, clear-shanked plants; these being ready, stretch your line along the middle of the beds, and at every yard distance put in three plants in a triangle five or six inches apart, or, if you plant five, set one in the centre, and the others regularly round it; directly give a little water, and put on the glasses, which keep close about ten or twelve days, when the plants will have taken fresh root; then prop them up on the sunny side about three inches high with forked-sticks, pieces of brickbat,

or the like, but it is the most handy to have wooden pegs fifteen inches long, each having one or two notches to receive the edge of the glass, so sticking them in the ground, one for each glass, and by which the glasses may be readily propped higher or lower on any side, as occasion requires.

During winter, the glasses are to be kept almost constantly over the plants, observing, however, in mild weather, to keep them tilted on props, as above, on the warmest side, for the admission of air, and in fine mild days it is proper to set the glasses quite off, which, if your plants are rather forward in growth, should be practised at all opportunities, lest, by too constantly glassing, it draw them into flower, but always put the glasses over the plants at night; when cutting winds and frosty weather prevail, keep the glasses close down, only raising them in the middle of sunny days, and when extremely severe frost, keep them as close as possible, and, for the greater security at such times, it is eligible also to lay some long litter close about the lower part of each glass, raising it higher as occasion shall require, all of which precautions are to be occasionally repeated from the time of planting them under the glasses until spring.

As to their spring culture, in the first place observe, that if all the plants under each glass have survived the winter, they must be thinned the beginning or middle of March, for two stout plants under a glass is sufficient finally to remain; though in large bell-glasses, the market-gardeners about London frequently leave three plants under each, for the sake of having the advantage of the glasses to bring as many as possible to early perfection, which, though smaller than if but one or two, yet by coming in two or three weeks earlier than those planted out, they sell at double or treble the price; but where the size of the Cauliflower is a principal object, I should advise to leave but two of the best plants at most under each glass, and transplant the others into another place the beginning or middle of March, according to the temperature of the seasons, at which time a piece of rich well-dunged ground must be prepared to receive them; when this is ready, proceed to thin out the weakest plants as above, raising them with the point of a trowel, to preserve the fibres of their roots, being careful not to disturb, or leave any vacancy about the remaining plants, observing, if there are any deficiencies, to make them good, in the first place, with
some

some of the best of those thinned out, and plant the rest in the place prepared for them, two feet and half distance each way, and give some water to settle the earth about their roots; but in planting out these plants, it is customary with gardeners, who have occasion to make the most of their ground, to sow a crop of radishes and spinach on the same plot, as directed for the main summer crop.

The remaining plants under the glasses should directly have the earth made good about them, and draw a little mould up about their stems, continuing to cover them occasionally with the glasses, which must be raised considerably on props, in proportion to the advanced growth of the plants, not omitting to let the plants enjoy the benefit of the full air in mild days, also that of warm showers, by setting the glasses wholly off.

Thus the glasses are to be continued occasionally over the plants until the middle or latter end of April, or longer, if it shall seem necessary, either according to the growth of the plants, or temperament of the weather, observing, that when the plants are so far advanced that their leaves press against the glasses, these should be raised, by forming a border or ridge of earth round each hole of plants three or four inches high, on which ridge of mould set the glasses, continuing to prop up one edge occasionally, as before, and accordingly as the plants advance in growth, it is proper to prop up the glasses on every side three or four inches in height, for now, as the length of the days and warmth of the weather encreases, the plants will grow freely, so must have as much free air and scope to grow as it is possible to allow them under the glasses, at the same time being careful to expose them also occasionally to the full air, as before observed, in fine days, and moderate warm showers, but continue to defend them with the glasses on nights, and in immoderate cold rains, and all boisterous weather, at least until the weather becomes warm, and the plants are grown too large for the glasses, then let them by degrees be fully exposed night and day, so that by the middle or latter end of April, the use of glasses may be wholly discontinued.

If the weather, toward the middle or latter end of April, and beginning of May, prove hot and dry, moderate waterings will be of utility in promoting the progress of the plants, as well as encreasing their size and strength; for it is of importance to have the plants as

large and strong as possible when arrived at full growth, otherwise we cannot expect them to produce large Cauliflowers.

About the middle of May some of the forwardest plants will probably shew flower, at which period examine your plants daily, and whenever a flower appears, turn down some of the inward leaves, to screen it from the Sun's rays and free air, which would change it to a yellow hue, and occasion the head to open before it attained its due perfection.

The excellence of a Cauliflower consists not only in the size, but also in the whiteness and compact curdy-like growth of the head; such that assume a frothy loose appearance, are a degeneracy, and are in every respect inferior.

A Cauliflower is in its utmost perfection of growth when the outward parts of the circumference begin to open and expand, after which appearance the whole head soon divides, and shoots up fast for flower and seed, therefore watch the opportunity, for a day or two often makes considerable difference.

In gathering the Cauliflowers for use, it is worth observing, that they eat considerably more crisp and sweet when cut in a morning, though this is not always practicable in families, because it is often the middle of the day before the gardener is informed what is wanted for the kitchen: they may either be cut off the stalk as it stands, or the whole plant may be pulled up; for, as the stalks never produce sprouts like those of cabbages, it is of no use after the main head is gone; they however must be divested of the root-end of the stalk before they are carried in to the kitchen or market; but if they are not to be immediately used, permit the whole stalk and leaves to remain, and lay them in a cool place till wanted.

Thus far for the culture of the bell-glass crop.

As to the culture of the main summer crop, which I before advised to be wintered in frames, &c. observe the following directions.

These are designed to be protected all winter in frames, &c. in order to be planted out in the spring, to succeed the early crop which were finally planted out in autumn under the bell or hand-glasses; and even where there are no such glasses, it is essentially necessary to raise a quantity of plants in autumn, as before directed, and pricked in garden-frames, to be occasionally covered with the lights during

ing winter, because they will come in much sooner than a spring-sown crop; or, in default of frames, prick a quantity in a bed arched over with hoops to be covered with mats, for, although some may be planted close under the bottom of a warm wall to take their chance, and will frequently struggle through our ordinary winters, yet they are not always to be depended on, and, at any rate, they come in later, and rarely attain the size and perfection of those occasionally protected as above.

Therefore the plants being raised as before directed, proceed, in the end of October, or beginning of November, to prepare a bed or beds of rich light earth, in a dry sunny situation, the width and length of one or more garden-frames, &c. fronting the south, raising the surface a few inches above the common level, and rake the top smooth; then mark out the width of the frame, and prick the plants therein in cross rows three inches asunder, give a little water, and directly put on the lights, which keep constantly on eight or ten days, when the plants will have taken root, and must then be fully exposed, in mild weather, to the open air. During winter, every day, in open weather, expose the plants fully to the free air, by shoving the glasses entirely off, which, however, should always be put on at nights; likewise in excessive rain, though if the rain happens in the day-time, and the weather is mild, raise the glasses on props three inches high, for the admission of fresh air, for they must by no means be kept too close in mild weather, lest it force them into flower, as observed of the bell-glass crop, which would render them useless. In sharp frosty weather the glasses must be kept always on, except in the middle of sunny days, and the glasses should be covered on nights with dry litter or mats; also if the frost is very severe, lay long litter round the outside of the frame. All decayed or yellow leaves should be constantly picked off as they appear during their residence here. Towards spring inure them gradually to the full air, by leaving the glasses off occasionally on nights as well as days, in open mild weather, so as that by the end of February, or beginning or middle of March, they may be hardened to be removed to the place of their final destination.

In default of frames, &c. as above observed, you may, at the before-mentioned time, prick a quantity of plants in a four feet wide bed in a sheltered situation, which

arch over with hoops or rods; so on nights and all bad weather cover with large garden-mats, and in severe weather also with litter.

Likewise in the above cases of the want of frames, &c. a quantity may be pricked on a south border close under the wall, &c. and in default of other covering, they may be lightly covered in severe frost with dry long litter, by which assistance the plants will often survive the winter, and, at any rate, will come in earlier than spring-sown plants.

In the latter end of February, or beginning or middle of March, according to the temperature of the weather, and condition of your plants, all those wintered as above, either in the frames, arched bed, or warm border, are to be planted out, where they are finally to remain. Make choice of an open spot of the best ground, which should be previously dunged and dug, as directed for the early crop, and in which plant the Cauliflowers by line two feet and half distance every way, and give water; but if it is necessary to make the most of your ground, a crop of radishes and spinach may also be raised on the same plot, which should be mixed and sown together broad-cast, and raked in, before you plant the Cauliflowers. The radishes and spinach come in for use in May, and will be all gone by that time the Cauliflower-plants begin to advance considerably, when the ground should be well hoed, and earth drawn about the stems of the Cauliflowers, observing, if the month of June proves very hot and dry, occasional waterings will be of great utility, forming basins round each plant for that purpose, and in July this crop will be in full perfection, continuing in succession until the middle of August, when they will be succeeded by the late summer crop.

The culture of the late summer crop is,

In order to keep up a regular succession of Cauliflowers through the summer, it is necessary to raise a due supply of plants in spring, to be planted out in the latter end of April, or in May, which will arrive at perfection in August and September, in due time to succeed the autumn-raised crop.

This crop may be sown any time in February, but not later than the first week in March, and, in order to forward the plants as much as possible, it is proper to sow the seed in a hot-bed of slender structure; let the hot-bed be made for a one-light box about eighteen or twenty inches depth of hot dung, covered with light rich earth four or five

five inches thick; sow the seed on the surface, and cover it a quarter of an inch deep with fine mould, put on the glass, and give occasional light sprinklings of water, raising the glass daily, for the evaporation of the steam, and admission of fresh air, and the plants will rise in a few days, at which time admit air freely by tilting the glass, and by taking it wholly off in fine warm days and moderate showers, and in dry weather give frequent light waterings. When the plants have leaves an inch broad, it is proper to prick them out, and if some are then pricked upon another hot-bed of moderate temperature, it will forward them considerably. In default of frames, may sow the seed and prick the plants on a hot-bed of the above substance, defended in cold nights and bad weather with mats or hand glasses; or, for want of a hot-bed, may sow the seed, &c. on a warm border, and cover occasionally, as above.

About the latter end of April, or beginning of May, some of the forwardest plants will be fit to transplant for good, which should be in an open spot of rich well-dunged ground, as directed for the former crops, and in dry weather should have frequent refreshments of water till they have taken good root; their further necessary culture is only occasional hoeing to kill weeds, and when the plants are somewhat advanced in growth, draw some earth about their stems.

The culture of the Michaelmas crop is,

To have Cauliflowers after Michaelmas, and to continue from October till near Christmas, is, as already observed, effected by sowing about the 24th of May on a bed of common earth, and when the plants have leaves an inch or two broad, prick them out three or four inches asunder, to remain until the latter end of July, then transplant them finally, as directed for the other crops, supplying them occasionally with water till rooted; they will begin to shew heads towards the end of October, which will continue coming in gradually all November, and if the season proves mild, they often continue great part of December.

This crop depends greatly on the temperature of the autumn after Michaelmas, which, if moderately dry and warm, we often have tolerably large handsome Cauliflowers in November, but if very wet and cold, the heads, for the general part, are small, irregular, ill-coloured, and insignificant.

Saving the Seed of these Plants.

Every gardener who cultivates any considerable quantity of Cauliflowers, should be

particularly anxious about saving his own seed from the most perfect sorts, as those who save great quantities for sale are not over careful in that point, which is the reason we often meet with so many irregular, ill-coloured, frothy, loose, and other spurious kinds, in private gardens, to the great disappointment of many gardeners.

Some of the earliest sorts of the bell or hand-glass crop, are to be selected for seed, for those of the succeeding crops are rarely forward enough to ripen any; the most perfect, largest, compact, firm white heads, are to be marked, and permitted to remain in the same place to run up to stalks, &c. which they will effect in July, when they will also flower, or in the beginning of August, and perfect seeds in September; observing, when the flower-stems are considerably advanced, to place three stakes triangle ways, for the support of each plant, and by encompassing the stakes with pack thread, or other tying, it will effectually secure the stems, and all the lateral branches, in their due position, which is all the culture necessary, unless the weather proves very dry after the seed-pods are formed, when some moderate waterings all over the plants will be very serviceable, not only in the growth of the seed, but also in preserving it from the mildew, an infection which often attack these plants so severely in their seeding state, as either totally to destroy the greatest part of the seed, or retard its growth so much, that it never ripens perfectly, and is the reason of good Cauliflower-seed being often so dear, which in the shops is frequently sold from two to four shillings per ounce.

In the middle of September the seed will begin to ripen, though in cold wet autumns it is sometimes Michaelmas before that is thoroughly effected, being watchful, however, to cut off the branches according as the seed ripens, for they do not all ripen together, so tie it in bunches, and hang it in the sun to harden, then beat it out, and put it up in bags for use.

A fresh parcel of seed should be saved annually, for this seed is not to be depended on when more than one year old, though two year old seed will frequently grow.

Sixth Division.

BRASSICA *Italica*, Italian *Brassica*, commonly called Broccoli.

The Broccoli is another supposed variety of the common cabbage, though, if we admit of the cauliflower as a distinct species of *Brassica*, the Broccoli is more apparently related

lated to that species than the cabbage, so that we have reason to suppose all the sorts of Broccoli varieties of the *Brassica Cauliflora*, as the plants, both in their general growth, habit, and eatable parts, greatly resemble that species; for, as we observed of the *Cauliflora*, all the varieties of Broccoli form roundish heads in the centre of their leaves, composed entirely of a compact collection of numerous buds or ends of advancing shoots, and which, like the cauliflower, are the chief eatable parts of the plant; that being used while they remain compact and firm, are most excellent eating, but after having attained a certain state of growth they divide, assume a seedy-like appearance, and soon fly up to stalks for flower and seed.

There are several varieties, all of which are cultivated principally for winter and spring eating, though the spring crops always attain the greatest perfection, being productive of the largest and finest heads; but, as a regular succession may be obtained from Michaelmas until May-day, and being the most excellent winter and spring vegetables of our gardens, their culture highly merits our nicest attention, to obtain a regular supply during the above period.

All the varieties are hardy enough to resist the cold of our ordinary winters, though very severe frost often affects such that are weak or grow in exposed cold soils, but more particularly the sort called Cauliflower-Broccoli.

The botanic title of Broccoli is,

BRASSICA Italica, the Italian *Brassica*, by the Italians called Broccoli.

The principal sorts, and their respective varieties, are,

¹*Early Purple Broccoli.*] A moderate-growing darkish-green plant, producing smallish purple heads, but comes earlier by a fortnight or more than any other, and of which there are, the purple, the green, and the blue, all often rising from the seed of the same plant; this sort is proper for the first crop, which, if sown the latter end of March, or beginning of April, and planted out in June, come in for use from Michaelmas till Christmas, and when the heads are gathered, the stalks produce plenty of fine sprouts of excellent eating.

²*Late Purple Broccoli.*] A large, robust-growing, darkish-green plant, producing a large purplish head like a cluster of buds, being generally much larger and more perfectly headed than the former sorts, and is very de-

licate eating, of which there are, the Common Purple-headed Broccoli—Blue Broccoli—Brown Broccoli—Green Broccoli—Yellowish Broccoli—all of which frequently rise from the same seed, though that of the true purple kind is superior both in size and perfectness of heading, as well as delicacy of eating, and with care in saving the seed, the sorts may be continued, and this, and all its varieties, by sowing in April, or early in May, and beginning of June, and planting out the plants in July and August, may be obtained for use from about Christmas until the beginning or middle of May, but are always in greatest perfection in regard to size in March and April; and after the main head is cut, the stalks exhibit abundance of side shoots or sprouts, terminated by small heads, which eat as sweet and tender as the main ones.

³*White, or Cauliflower-Broccoli.*] A very curious variety of Broccoli. The plants are of robust growth, and lightish-green colour, forming fine white heads in the centre, sometimes as large as a middling cauliflower, and greatly resemble them in every state of growth, and for delicacy of eating is equal to the finest summer cauliflower whatever. This sort admits of no varieties, except in different degrees of whiteness, though the whitest generally assumes somewhat of a yellowish hue; that, by sowing seed in April and May, and planting out the plants in June, July, and August, you will obtain heads for use all winter and spring; but those that appear about March, and beginning and middle of April, are considerably the largest and fairest heads. The stalks of this sort rarely afford any sprouts like the purple kinds.

⁴*Black Broccoli.*] A tall-growing plant of a blackish-green colour, which, for the general part produce small and imperfect heads, being somewhat open and seedy-like, but possess this property of being so hardy, as seldom to be injured by the severest frost. There are of this the Black or Dark-headed Broccoli, the Brown, and the Blue, all sometimes from the same seed, and are proper to cultivate to stand the winter, by way of reserve for spring service, sowing the seed early in May, and planting out the plants in July.

Their General Culture.

All the varieties are propagated by seed annually in the common ground, sowing them in spring in an open situation, and the plants to

to be transplanted into an open exposure, as hereafter directed, to grow to perfection.

The principal seasons for sowing is March, April, and beginning of May, according to the time the plants are required for use; as for instance, if the heads are desired in October, November, December, and January, it is proper to sow some of the early and late purple kinds any time from about the 20th of March to the fifth of April; also at the same time may be sown a few of the Cauliflower-Broccoli, by which you will obtain the greater chance of succession and variety; the early purple will come in first, and they will be regularly succeeded by the others; but for the main spring crops, to come in for use in January and February, and continue in succession until May, the season for sowing them is from about the fifteenth of April until the fifth of May, according to your situation and temperature of soil, and for which crops the late purple and Cauliflower-Broccoli are the principal sorts; at the same time may also sow some of the Black-Broccoli, to stand by way of reserve, in case the others are injured by the winter's frost; and if you would continue a longer succession, a third sowing may be performed the end of May, or beginning of June, particularly of the late purple and Cauliflower-Broccoli.

By observing the above different times of sowing the seed, a succession of Broccoli may be obtained for use from October until the middle of May.

The seed, as before observed, should be sown in an open exposure, where the plants will rise much stronger than on narrow borders, under walls, &c. sow each sort separate, scattering the seeds moderately thick on the surface, and rake them in; the plants will come up in ten or twelve days; give occasional waterings in dry weather, and when they have leaves an inch broad, it is proper to prick out a quantity of the best in a nursery-bed three or four inches apart, giving water as soon as planted, and occasionally till they have taken root, in which bed let them remain a month, or five or six weeks, where they will acquire due strength, their stalks will be short and of robust growth, and will hereby be considerably better prepared for transplanting where they are finally to stand, than those which remain in the seed-bed.

The time for transplanting them where they are finally to remain, is June, July, August, and beginning of September, according to

the time they were sown, or are desired for use.

The plants should have an open situation, and as good ground as any the garden affords, which, if it has the addition of dung, will be a particular advantage, digging it in neatly one good spade deep, and directly put in the plants, for which work a moist time would be highly beneficial; they are to be planted in rows two feet and half asunder, and about twenty inches distant in the lines; but for those planted late, i. e. in August and September, two feet at most between row and row is sufficient, and eighteen inches distant in the rows. Let them, as soon as planted, be watered, and if dry weather prevail, repeat the watering every other day, till the plants have got root, which work should be particularly attended to in transplanting these plants.

After the plants have taken root and begin to grow, their further culture is to keep them clear from weeds, by hoeing the ground occasionally, and when they have advanced a little in growth, draw some earth with an hoe about their stems, which work of earthing, if repeated, will be of singular advantage to the plants; it will promote their rooting more firmly in the ground, and encourage their progress of growth, and greatly forward them, so as to acquire due size and strength before winter, which is very essential, for if the plants do not by that time arrive to a tolerably large growth, they will yield but small and trifling heads.

Some of the earliest plants will probably shew heads for use in October and November, or perhaps sooner, which however are rarely so large and fine as those that appear towards, and after Christmas.

Previous to gathering the Broccoli for use, attention must be had that the heads be permitted to have their full growth, which, however, should be cut while they remain close, and before they begin to divide and assume a feedy-like appearance, and should be cut with about six inches of the main stalk to each head; for the upper part of the stalk eats exceeding sweet and tender, which, previous to its being dressed, must be peeled or divested of the outer rind, and which, when dressed, as well as the heads themselves of the Purple and Black-Broccoli, always assume a fine green colour; but the Cauliflower-Broccoli retains its natural whiteness, which should be boiled in a clean linen cloth, as practised to

cau. i.

cauliflower, and should be served up to table in the same manner.

After gathering the main heads of all the sorts of Purple and Black Broccoli, the stalks should be permitted to remain for the production of sprouts or smaller heads, which they will afford plentifully, and which are as fine eating as the principal heads; but as to the Cauliflower-Broccoli, the stalks afford but very few sprouts or side-shoots.

To see Broccoli in high perfection from the earliest to the latest period, we must review Covent-garden and Newgate-markets, in London, early in a morning from October until May, there we may see the production of numerous different gardeners brought in great quantities, all bound up in bunches by their stalks, from six to twelve heads in each bunch, those of the purple sorts all divested of their leaves, the cauliflower kinds with the leaves on, but which are trimmed down to the head in the manner of cauliflowers, and both of which sorts are there sold from about three or four to eight or ten shillings per dozen of bunches, according to the size and quality of the heads.

Of saving the Seed of the different Sorts.

When it is intended to save the seed of Broccoli, some of the largest and most perfect heads of the respective sorts of those which appear in February or March should be marked when in perfection, which, of the first and second sorts, those only of the best purple colour and close knobby-like heads should be selected; and of the cauliflower or white sort, those that have the largest, closest, and whitest heads, are to be chosen; and of the black kind, always chuse those with the largest, most compact, and darkest-coloured heads; all of which should remain untouched, only taking off the side-shoots, so leaving only the principal head to shoot up for seed.

To preserve the principal varieties as pure in their kind as possible, the seeding plants of the different sorts should be at a considerable distance, lest they fecundate each other, and occasion a degeneracy.

Those persons who cultivate purposely for seed, should sow in the end of April or beginning of May, and plant them out in July; and the following spring, when they shew their heads, pull up all those that are degenerated, or vary from their respective kinds, which should be punctually attend to, otherwise it will be impossible to preserve the sorts.

All the sorts generally ripen seeds as plentifully as any of the sorts of cabbages.

The plants generally run up to stalk in April or May, flower in June, and the seed ripens in August, which is to be managed as directed for that of cabbages, savoys, &c.

Seventh and last Division of Brassica.

¹BRASSICA RAPA, the Turnep.

The Turnep, as we have already observed, is a distinct species of *Brassica*, or Cabbage, which till lately was always ranged as a separate genera, under the title of *Rapa*; but its general characters being the same as *Brassica*, modern botanists have now ranged it as a species of that genus.

Class, order, and characters, the same as *Brassica*.

The botanists allow but one distinct species, but which admit of several eminent varieties, all of which are annuals, as, if sown early in spring, they attain perfection, run up to flower, ripen seeds, and totally perish the same year.

The species is,

BRASSICA *Rapa*.

Rapa, the Turnep] *Brassica* with a large, orbicular, depressed, fleshy root, crowned by many long rough leaves, and when the plant spindles, rises with a strong erect stem three or four feet high, dividing into many branches, covered with numerous yellow flowers in May and June, succeeded by plenty of ripe seed in July or August.

Varieties of this are,

¹*Early Dutch Turnep*.] An orbicular, moderate sized, handsome, white Turnep, valuable for its early perfection, very sweet and tender while young, and a very fine garden Turnep for the early and summer crops, though when old it is apt to become stringy.

²*White Round Turnep*.] A globular, large, white Turnep, proper both for the garden and field culture, and succeeds the Dutch sort in its time of attaining perfection.

³*Green-topped Turnep*.] A large round Turnep, remarkable for having its outer coat green at top, and great part of the root growing above-ground; is exceeding tender and palatable eating at almost every period of its growth, obtaining in size from about four to eight or ten inches diameter, though, when allowed considerable room to grow, it often arrives at a much greater magnitude, and is excellent for the general crop in gardens, as well as that of field-culture for feeding cattle.

⁴*Red-topped Turnep*.] A large globular Turnep, having its outer skin red at top; a fine, soft,

soft, sweet-eating root; and as it acquires a very large size, is also particularly well adapted for field-culture.

⁵*Yellow Dutch Turnep.*] A moderately large, and frequently oblong Turnep, the skin and flesh of a yellow colour; is tolerably sweet and palatable eating, though the colour renders them disagreeable to some, whilst others esteem them equal to any of the other varieties for the table.

⁶*Oblong White Turnep.*] An oblong, largish, white Turnep; strikes considerably into the ground, often assuming the form of some parsneps; boils soft and sweet while young, but soon becomes stringy and rank-tasted.

⁷*Long-rooted French Turnep.*] A long, small, spindle-rooted Turnep, of but little merit except for soups, and should be used while young, otherwise it becomes stringy and hard.

⁸*Purple Turnep.*] A roundish, small, early, purple-coloured Turnep, considered more as a curiosity, than for any economical purposes.

Of the above varieties, the first four are those of most merit, the first of which demands notice for the early summer crops for family service, they generally arriving to perfection a fortnight, at least, sooner than any of the other varieties, and may be obtained so early as the middle of May, at which time, or when the root attains the breadth of a shilling or a half-crown piece, they are also esteemed by many to eat raw, either alone, or as an ingredient in the composition of a salad, serving them to table with part of their green tops entire, as also the long fibre or tail of the root; and for culinary purposes they may be continued in great perfection all summer, by performing three or four different sowings from March until July, so as to have crops of young roots succeed one another regularly; but for the autumn and winter crops, the white round Turnep, the green-topped, and the red-topped kinds, are the hardiest and very fine family Turneps, though the green-topped sort claims precedence for sweetness of eating, as well as durability of perfection; likewise, as the three last-named varieties attain considerably the greatest magnitude, they are to be preferred to all the others for field-culture, for the feed of sheep and black cattle in winter and spring; and for the general supply of table in autumn and winter, it is eligible to cultivate a good crop of the white-round, or green-topped kinds,

&c. by sowing at the seasons hereafter directed.

Turneps may be obtained for use eight or ten months in the year, that is, from about the middle of May, until the beginning or middle of March, after which time they begin to shoot up into stalk for seed; and although the roots are often continued for use until the latter end of April, yet they, after the month of March commences, soon shoot, become stringy, dry, hard, and very indifferent eating for the table.

General Culture.

The propagation of all the varieties is by seed in an open situation, in the place where the plants are to remain, for they are never transplanted like the preceding species of *Brassica*.

The season for sowing is any time from the beginning of March until the latter end of July, though to have a long and regular succession for the table from the earliest to the latest period, it is necessary to perform four or five different sowings, at least, at proper intervals, from the middle of February until the middle of August, observing it is not adviseable to sow earlier than the middle of February, because the too early sown plants would fly up to seed the same year before the roots apple, or, at least, attain a quarter their usual size; indeed, even those sown any time in February are very apt to run; but those sown in March more generally stand, and all those sown after that time, as in April, May, June, &c. never run till the spring following; and as to the latter crops, none should be sown much later than the middle of August, as above noticed, by reason the roots will not have time to grow to any tolerable bigness before the winter's cold puts a period to their growth; it is however proper to sow late as well as early for family use, that, although the roots will not acquire any considerable size, they being reserved for spring, stand three or four weeks longer before they run, than those of the summer crops, by which means we obtain them so much the longer for the table.

But for the general summer, autumn, and winter crops, the principal periods for sowing is April, June, and beginning of August, as before observed, though, where a constant supply of young roots are required, sowings may be performed in any of the intervals between these times, or those before-mentioned.

An open situation, and a moderately light soil is the most eligible for the culture of Turneps; as, in confined places, they draw up greatly to tops, and form but inconsiderable roots, and in strong land the roots frequently acquire a stringy texture, and rankness of taste.

The necessary space of ground to sow at a time for the supply of a family, is from about two to six, eight, or ten rod, making the calculation according to the extent of the family.

The proper quantity of seed is at the rate of about two pounds to an acre, so the calculation is easily made for a smaller or larger extent of ground.

The ground is to be prepared for the seed, by digging or trenching it one spade deep, and the seed should, if possible, be sowed while the ground is fresh stirred, especially in summer, when it is hot or dry weather, but a moist season for sowing is of great importance in the culture of Turneps, for reasons hereafter explained: the seed is to be sown broad-cast on the surface, scattering it moderately thin with a regular cast, and even-spreading hand, and directly tread it in evenly, and rake the ground; thus far is the method of sowing Turneps in gardens; but in the field culture the plough, harrow, and roller, is used. See the *Field Culture*.

This seed being of quick germination, the plants appear in a few days after sowing, especially in moist weather; and in eight or ten weeks after they appear, we may expect Turneps fit to draw.

As we above observed, a moist season is of great advantage in sowing Turneps; it promotes a quick germination in the seeds, and free growth in the young plants; for when they come up freely, and continue a luxuriant growth, it secures them from the fly, which, in very dry weather, when the plants rise straggling, and grow stuntedly, while in the seed leaf, often proves a mortal enemy to these crops, frequently destroying whole fields of them in a few days; but when the weather is showery at their first appearance, the plants advance so fast in growth as soon to be in the rough leaf, and after they begin to advance in the rough leaves pretty strongly, they may be considered to be past danger; so that the greatest danger is the first week or fortnight after the plants come above ground, therefore in gardens, where there are only small quantities, it will be highly beneficial to water

them plentifully at that period of their growth. Many receipts have been recommended to prevent the attacks and devastations of this common enemy to our Turneps, such as steeping the seed, previous to sowing it, ten or twelve hours in water, wherein has been boiled or infused a good quantity of tobacco-stalks and dust, mixing therewith flour of brimstone, foot, juice of hepatic aloes, &c. also by strewing foot or lime over the ground after the plants come up, which expedients frequently have some effect, though far from being infallible, for, in spite of all the methods, the fly will often devour whole crops, if ever so considerable; and when this is the case, nothing more can be done than to prepare the ground, and sow it again as soon as possible.

As to the general culture of Turneps, the plants, as before observed, are always to remain where sown, and all they require is, when about a month old, to be thinned to from about six to twelve or fifteen inches distance, and cleared from weeds, which work of thinning, &c. is the most effectually done by the hoe, and is called hoeing Turneps.

This work of hoeing Turneps is to be performed when the plants have two or three leaves about an inch broad, which should always be done in dry weather, see HOEING, having a common large hoe five or six inches broad, with which cut down the superabundant plants, singling out the others to about eight inches distance, though, if the turneps are to stand to grow to full size before any are drawn, they should be thinned to a foot distance at least; at the same time cut down all weeds, and stir every part of the ground, for this is highly beneficial to the growth of the plants, and if the work is duly performed in dry weather, that the weeds, &c. cut down be more effectually destroyed, the plants will require no further culture; for they, after the operation of hoeing, will advance so fast in growth, that their leaves will soon spread and cover the ground, so as to stop the future progress of weeds. With respect to the above distances of thinning the Turneps, it is principally to be understood of such that you intend shall grow to a tolerably large size before any is drawn; but as to the earliest crop, they need not be thinned to more than five or six inches distance, especially if it is intended to begin drawing them as soon as they begin to turnep, as by many practised, gradually thinning out the largest for

for use; observing, however, always to thin them regularly at first, as above, at the time of hoeing.

In three or four weeks after hoeing, the plants will begin to turnep, and in five or six some will be fit to draw young for use, but it will be two months from hoeing before they attain tolerable perfection, though, as above observed, we often begin drawing the earliest crop as soon as the root begins to turnep, which, although not larger than middling walnuts, are always highly acceptable at an early season, as a rarity at table; they also sell well at market, and those of London are generally supplied with them so early as the beginning of May.

The quantities of these roots consumed for family use almost the year round in London and its vicinity are amazing, when we survey the vast crops in the extensive garden-grounds and fields eight or ten miles round the metropolis; also Covent-garden, and the other gardener's markets of that city, early in a morning, to see the prodigious quantities that are daily brought by cart and waggon-loads, all clean washed and neatly bunched, from about twelve to fifteen or eighteen, &c. according to their size in each bunch, and which the gardeners sell to the retailers by the dozen of bunches, generally from one to two shillings per dozen.

Of the Field Culture.

In the field culture of Turneps for autumn and winter service, either for the supply of markets or for feeding cattle, the common season for sowing is any time from the beginning of June till the middle of August.

The ground is to be prepared for the seed by proper ploughing, and should also be once or twice well harrowed, to render the surface level and fine, that the seeds, when sown, may be more equally covered; the seed is then to be sowed immediately, allowing not more than a pound and half or two pound to an acre, sowing it by broad-cast, and directly harrow it in with a short-tynd harrow, and afterwards roll the ground with a large wooden horse-roller to smooth the surface, and the seed will thereby be covered more effectually, the plants will rise more regular, and will be much easier to hoe them, than if the surface is left rough.

When the plants have leaves an inch or two broad, they are to be hoed in dry weather, to destroy weeds, and thin the plants to twelve inches distance, as before observed; but when

it is designed the roots shall grow to their utmost size for feeding cattle, it is proper to set them out to about fifteen inches distance at least.

The crops of the above times of sowing come in for use in September, October, and November, and continue good all winter, either for the table, or for feeding, at which time they are admirable food for sheep and cattle, and are excellent for milch-cows, for which purpose the cow-farmers about London use vast quantities, many of whom have several hundred cows, but as their land consists chiefly of grass, they buy whole fields of them of the ploughing farmers ten or fifteen miles round the city, and bring them home in waggons, and give them to the cows whole, which they eat greedily, to the great encrease of the quantity of their milk.

Saving the Seed.

To save Turnep-seed, a due quantity of the roots of the autumn or winter crops may be permitted to stand where they were raised, and they will shoot up in March, and produce plenty of seed in June, July, or August, without further trouble; but if you are curious to preserve the different varieties in as great perfection as possible, it is adviseable in February to transplant a quantity of the finest roots of each sort in separate pieces, at a distance from each other, placing them in rows two feet asunder, and the necessary culture is, to hoe the ground occasionally to destroy weeds, and to watch the birds when the seed begins to ripen, which will be in June or July, and some time in these months, or beginning of August, will be fully ripened, when the stalks should be cut up from the bottom, and after it has been exposed to the sun a few days to dry and harden, thresh it out, and put it up in bags for use.

BROMELIA, *Bromelia*, comprehending also the **ANANAS**, or Pine-Apple, and the **PINGVIN**, or Wild Ananas.

This genus comprehends most curious exotics for the hot-house, herbaceous perennials of robust aloecaceous-like growth, rising with numerous, long, erect, sharp-pointed leaves from the bottom; in the midst an erect stalk from one to three feet high, crowned by oblong ovalish fruit; and that, being natives of the hot parts of Africa and America, they consequently, in this country, require the constant shelter and temperature of our best stoves.

Class

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, a small, trigonous, three-parted, permanent cup. COROLLA, three narrow erect petals, having at the base a three-parted nectarium. STAMINA, six short filaments, inserted into the receptacle, crowned by sagittated antheræ. PISTILLUM, a germen below the receptacle, and filiforme style, surmounted by an obtuse bifid stigma. PERICARPIUM, a large, roundish, umbilicated, baccaceous fruit, furnished with numerous, small, oblong, obtuse, smooth seeds, which in the Ananas are lodged in the knobs or tubercles of the fruit.

There are of this genus four or five species, the principal of which is that celebrated plant the Bromelia Ananas, which produces the so much admired fruit the Pine-Apple, and which now constitute the principal furniture of most of our hot-houses, for the sake of the said fruit, which certainly deserves the appellation it has universally obtained, that of king of fruits, as, in beauty, delightful fragrance, and deliciousness of taste, it greatly surpasses all other fruits of the world.

The species are as follow: and first of the Pine-Apple and varieties.

¹BROMELIA *Ananas*.

The Ananas, or Pine-Apple Plant.] Bromelia with a thick, fibry, perennial root, crowned by many long, erect, sharp-pointed, serrated, prickly leaves, growing two or three feet high; from their centre a robust round stalk, supporting at top a large, oval, erect fruit, composed of numerous tubercles, and beautifully adorned at top with a crown of leaves, and blueish flowers, rising singly from all the knobs or tubercles, and as the flowers fade the fruit enlarges, becomes a fleshy substance, and as it ripens, assumes a golden colour, imparting a most fragrant odour.

Of the above species are several varieties, differing in the shape, size, and colour of their fruit, &c.

The varieties of note are] 1. Oval-shaped Pine-Apple with whitish flesh, or Queen-Pine—2. Pyramidal, or Sugar-loaf Pine-Apple with yellow flesh—3. Green Sugar-loaf Pine-Apple—4. Black Antigua, or Ripley Pine-Apple—5. Shining green-leaved Pine with scarce any spines, and with large fruit, or King-Pine—6. Granada-Pine with marbled leaves and very large fruit—7. Bog-warp-Pine with broad green leaves—8. Smooth, long, narrow-leaved Pine—

9. Gold-striped-leaved Pine—10. Silver-striped-leaved Pine.

Of the above varieties there are two principal sorts in esteem amongst us in England, which are the two first-mentioned, viz. the Oval Pine-Apple, and the Pyramidal, or Sugar-loaf Pine-Apple, the latter of which is superior to all the others in flavour, and is distinguishable by having the inner side of the leaves marked with purple stripes. Several of the other sorts are also cultivated in many of our curious stoves, both for the sake of the variety of their leaves, as well as that of their fruit, all of which attain due size, and ripen freely in our hot-houses, though preference is generally allowed to the two first varieties. As to the two striped-leaved kinds, i. e. the Gold-striped Pine, and Silver-striped sort, are the most rare of any sort in England, and are esteemed principally for the singularity of their striped leaves.

The four following species, not producing fruit of any consideration, are only cultivated in some curious hot-houses, for the sake of variety.

²BROMELIA *Pinguin*.

Pinguin, or Wild Ananas.] Bromelia with many long, sharp-pointed, prickly leaves from the bottom, and in the centre rises an upright stalk a yard high, terminated by a cluster of very small fruit, resembling a Pine-Apple.

³BROMELIA *Karatas*.

Karatas, or Acaulis Wild-Pine.] Bromelia with many very long narrow leaves from the bottom, strongly armed with sharp crooked thorns; and in the midst of the leaves rise a cluster of fruits near the ground, each about four inches long, and one broad; somewhat resembling the Pine-Apple.

⁴BROMELIA *Pyramidata*.

Pyramidal Bromelia.] Bromelia with many long, erect, aloe-like leaves, immediately from the root, sharply indented and armed with thorns; and in the centre issues a stalk a yard high, adorned below with entire leaves, and above with flowers, forming a loose spike, succeeded by small oval fruit.

⁵BROMELIA *Lingulata*.

Lingulated Bromelia.] Bromelia with many erect leaves from the root, narrow at their base, widening gradually to the top, and with serrated spinous edges; and in the midst of them the stalk, dividing into branches, sustaining alternate spikes of close-fitting flowers, succeeded by small, oval, pointed fruit.

These

These four species are propagated by seed ; also by suckers like the Ananas, and must always be kept in the stove.

Culture of the first Species Bromelia Ananas, or Pine-Apple.

The *Bromelia Ananas*, or Pine-Apple, and all its varieties, are herbaceous perennials of the evergreen kind, being perennial not only in root, but also in foliage, so may be said to be herbaceous evergreens ; and that being raised from seed, small suckers, or the crown at top of the fruit, they, until arrived at a fruiting state, consist principally of an erect cluster of long leaves standing on the crown of the root, the whole plant encreasing in substance and stature about two years, when they commonly produce ripe fruit, each plant one, appearing first in the centre of the leaves, generally in spring, crowning a robust stalk, which, as well as the fruit, grow perfectly erect, gradually advancing in height, and the fruit increasing in magnitude till July, August, or September, then acquires maturity, obtaining in size, from about three or four to six or seven inches length, and three or four diameter, always crowned at top with a beautiful tuft of erect leaves called the crown, serving not only as an ornament to the fruit, but also for propagation ; at the same time also of perfection of the fruit, the plants always emit suckers or off-sets, for the like purpose of propagation, issuing both from between the leaves at bottom, and just under the base of the fruit, after which the old plants, becoming useless for fruit-bearing, may be preserved as stools, to produce suckers ; so that a succession of young plants is always annually raised for fruiting, which is effected with great facility by the above-mentioned crowns and suckers : these being planted separately in pots plunged in the bark-bed in the hot-house, &c. as hereafter directed, where they soon strike root and grow freely, or may even be struck in a tan or dung hot-bed, made in a pit under a deep frame, or in hot-beds under a common cucumber or melon-frame, and afterwards removed to the stove to remain to come to perfection ; though the plants are by some reared by the benefit of tan or dung hot-beds only, under a deep glass frame, hereafter described ; but their culture is generally effected with greater facility and certainty in a hot house, having the aid of bark-beds and occasional fire-heat.

The appellation, Pine-Apple, given to this

plant, is from the resemblance of the figure of the fruit to the cone or fruit of the Pine-tree. See CONUS and PINUS.

This plant being a native of some of the hottest parts of Africa and South-America, in this country it requires the continual temperature of a hot-house, having the constant aid of bark hot-beds, &c. assisted occasionally in winter by actual fire, or in some such glass departments, where we can employ such artificial aids of heat, as sufficiently to imitate the temperature of the native climate of this plant, which by many is now so well effected in our stoves, as to raise the fruit in almost as high a degree of perfection as it usually attains in the above hot countries where it naturally grows.

It is raised in great abundance in most parts of the British West-Indies, and most other of the hot parts of America, where the plant grows freely at all times in the open ground, and from which country we were formerly supplied with many young plants ; but our hot-houses being now plentifully stocked with them, furnish considerably better plants than any procured from thence ; for those we receive from that country are often collected from good and bad sorts indifferently, and these frequently almost perished through the length of the voyage and ill-management ; so that the practice now of procuring plants from so great a distance is hardly worth the trouble, unless for the sake of some valuable new variety that shall happen to be discovered.

Holland was the first European country where the culture of this plant was attempted, and the temperature of heat discovered to bring it to a proper fruiting state, and from which country we here in England were supplied with the first plants and hints for its culture, in which we have so greatly improved as to equal, if not excel, all other countries of Europe.

The principal season of obtaining this fruit in perfection in England is from June until October, they generally shewing fruit in February or March, which advances gradually to perfection, acquiring maturity at different times, for the fruit of the same time of appearance are often a month or six weeks difference in their times of ripening ; but the time of their greatest perfection is August and September, though some plants being so backward in shewing fruit, that it ripens stragglingly in winter, and even some not until spring ;

spring; but their flavour is inferior to that ripened at the afore-mentioned times; so that in their culture we ought to promote their shewing fruit only in spring, that they may have the summer to effect their growth, by which they will obtain their due substance, beauty, and deliciousness of flavour.

Of the Hot-house or Stoves, &c. wherein to raise them.

Having before observed, that to cultivate these plants in England, or any part of Europe, they require the constant accommodation of hot-houses; with respect therefore to these departments, requisite particularly for these plants, it is further necessary to remark, that to effect their culture more commodiously, and so as to be well supplied with proper fruiting plants annually, it is proper to be furnished with two orders of such hot-houses or stoves; a smaller one to raise the plants, and a larger one to fruit them, each having a cavity or pit within-side the whole length, six or eight feet wide, and three deep, wherein to make the bark-bed, i. e. a hot-bed formed of tanner's-bark, in which to plunge the pots containing the plants; for this kind of hot-bed is most necessary in the culture of pines, and each of which departments to be also provided with flues, in which to make occasional fires in winter. See HOT-HOUSE.

The former of these departments, i. e. the smaller stove, is by gardeners sometimes called the pit, see BARK-PIT; or if of a more capacious dimension, the succession-house; and its use is by way of a nursery-stove to the main stove or fruiting-house, it being designed solely for the reception and rearing the young plants, that is, the crowns and suckers before-mentioned, which being planted singly in small pots in autumn, as hereafter directed, are plunged in the bark-bed of this small stove, to remain about a year, or until they attain a proper size and substance for fruiting, without encumbering or taking up the room in the principal fruiting-stove just-mentioned, by which means you will be able to fruit many more plants therein, than if the young and old were crowded together in the same department; besides, you can regulate the heat in this nursery-stove as the plants shall require, for they must not be much forced in their infant state, lest it drive them unseasonably into fruit, which, if it happens when the plants are less than fifteen or eighteen months old, the fruit, besides coming at an

untimely season, will be small and trifling; so that the intention is to rear the plants in this nursery-stove till they are a year or two old, when they will be nearly full-grown, or, at least, most of them will have acquired such size and strength, as to be capable of producing tolerably large fruit, and are then to be removed in autumn in their pots to the main or fruiting-stove.

And as to the fruiting-stove just mentioned, it is intended principally for fruiting the plants, after being reared from crowns and suckers in the nursery pit or succession-stove a year or two, till they obtain the size or bearing state above-mentioned, which being removed in their pots the beginning or middle of October to this main or fruiting-stove, and plunged in the bark-bed thereof, where, by the management hereafter directed, they commonly shew fruit the spring following, and which gradually arrive to perfection the ensuing summer and autumn.

For the proper dimensions of each of these stoves or hot-houses, see HOT-HOUSE, BARK-PIT, &c.

But where large quantities of these plants are cultivated, many, besides the above-mentioned stove departments, have also what is commonly called a bark-pit, formed by a deep frame of wood, or of brick-work six feet wide, the length at pleasure, five or six feet deep behind, and four and half in front, having the top glazed, see BARK-PIT; and is designed principally wherein to make a bark or dung hot-bed, for the immediate reception of the crowns and suckers from the parent-plants, as an ease to the succession-stove, by not crowding it too much, which is often at that time entirely filled with large succession-plants for next year's fruiting; but, by the time the crowns, &c. in this pit have struck root and begin to grow, the succession-stove will be thinned of the largest plants, to furnish the fruiting-house, which is generally in October, when the suckers and crowns in their pots may be removed to the succession-stove; though when that department is still crowded with larger plants, these small ones of the same year are often continued in the bark-pit all winter, or longer, if necessary, especially if the walls which form it are of brick, having flues on the back for fires, or even, if it is entirely of wood, the temperature of heat may be continued by the aid of strong dung linings against the outsides of the back of the frame, for it is also very possible

to strike the crowns and suckers, as above-noticed, by the aid of dung hot-beds only, either in the above bark-pit, or under common cucumber or melon-frames, covering the top of the dung with tan, wherein to plunge the pots containing the plants.

It is also even practicable to rear and bring these plants to produce ripe fruit by the benefit of dung-heat only, under deep frames, hereafter described, which, however, though attended with considerably less expence, requires more trouble, and the success never so certain nor equal to that of proper stoves, aided by bark hot-beds and fires in winter.

Crowns and suckers, however, as already observed, immediately from the parent-plant, may be readily struck and set to growing in tan or dung hot-beds without fire, under common garden-frames and glasses, and even if the bed is composed of dung, with tan at top, wherein to plunge the pots of plants, they, by the aid of two new beds, with occasional strong dung linings, might be continued there all winter, or, by the additional aid of a more capacious frame, in width and depth adapted to the height of the plants, they might be carried on to a due size for the fruiting-stove. See *Raising them without Fire*.

In many places, however, the whole culture of these plants is performed by the aid of one stove only, not having the convenience either of a succession-stove or nursery-pit, and the plants are raised and fruited all in the same department, though by this practice not above one half of the hot-house can be commodiously occupied at one time with fruiting-plants, the other half must consequently be employed in containing the succession-plants, and crowns and suckers, unless you fill the whole pit of the stove with the fruiting-plants, so crowd the pots of young ones in between them, as frequently practised; however, at any rate, when the young plants are raised in the same stove with those that are fruiting, and that we keep the stove in a due temperature to fruit them in full perfection, there is no certainty of keeping your crowns and suckers, and the succession-plants in general, from running to fruit unseasonably in their infant or half-grown state; hence the necessity is apparent of having a small stove solely for these young plants, or, at least, a bark-pit, or deep frame, which we above observed.

However, the most commodious and certain culture of this curious plant and fruit is, by the convenience of two orders of stoves,

at least, as we at first advised, having the constant aid of bark hot-beds.

Of the Tanner's-bark for the Bark-bed.

In regard to the tanner's-bark for the bark-bed, we formerly observed, that each of the above stove departments, &c. should have a pit or cavity formed within-side the whole length, wherein to make a hot-bed of tanner's-bark, in which to plunge the pots of plants, and which is commonly called the bark-bed; this kind of hot-bed is composed entirely of tanner's-bark, which being of such an agreeably moderate, durable, and nourishing heat to these plants, that without it we cannot bring them with certainty to fruit in any tolerable perfection; for fire-heat alone will not answer the purpose, as it dries and hardens the extreme fibres, and the plants become stunted, producing small ill-nourished fruit, ripening unseasonably late; whereas, by plunging the plants in the above hot-bed, the constant moist warmth it imparts to the mould and roots is excellently well adapted to the nourishment and growth of the plants and fruit: and that of the tanner's-bark is preferable to any compost of dung hot-beds for this purpose, and being also not only of three times longer duration in its heat, it never, like dung hot-beds, sends up noxious steams; and as to duration, the same bed with a little assistance, will support a growing temperature almost a year.

In respect to the time of duration just mentioned of the bark-bed, observe, it is commonly made in autumn, i. e. September or October, that it may be in good condition all winter, and it upholds a fine growing heat about four months, which, if then forked up to the bottom, renews its fermentation, and continues two or three months longer; then if in April you add about one third of new tan, the whole being again forked up to the bottom and mixed together, revives the heat substantially, and continues it in fine order till towards autumn, and by September and October it will be considerably exhausted, when the whole must be screened, and all the small earthy substance cleared away, levelling the larger in the bottom of the pit, and a large quantity of new is then to be procured from the tanner's, to fill it up again to the proper height, three or four inches above the kirk, to allow for settling; at the same time stir up and mix the old and new together, and this work of screening the old, and renewing

renewing the pit with fresh bark at the above time in autumn, is to be practised annually to each bark-bed.

For the choice of the bark, and some other particulars relative to this material, see BARK-BED.

Of the proper Soil for the Plants.

In respect to soil proper for the growth of those plants, they prosper freely in any rich, moderately light garden-mould, such as that of the kitchen-ground, where it is of a rich, fat, pliable temperature, and if somewhat of a loamy nature, of mellow texture, it will be an advantage, for nothing heavy, very wet, or stubborn, must be admitted; this mould may be got in readiness in a heap several months before-hand, adding thereto, if necessary, some thoroughly rotten dung; and if the soil is very light, it is proper to add about one half or a third part of fine pliable loam from the surface of a common or other pasture-ground, turning the whole over several times.

Or a compost may be prepared thus:

Procure from a rich pasture-field, or common, some mellow loamy earth, taking the top spit, not digging it out of deep pits, which is harsh and sour; to every load of this add about one third or fourth-part of a load of perfectly rotted dung of an old dung hot-bed; mix these well together, and form the whole in a ridge or long heap in the full air, in a sunny exposure, to lie at least six, but if ten or twelve months, or more, the better, turning the whole several times, that the parts may be properly incorporated, and receive equal benefit of the sun and free air; at each time of turning break all turfy lumps and clods, and when it is to be used break it fine with the spade, but not sift or screen any, which would render it too compact.

Of these composts it is proper to provide as much at first as will serve two or three years, since by lying together it will be much improved for the purpose intended, provided it is turned over three or four times annually.

Be careful never to use the earth at any time too wet.

General Method of Propagation.

As to the propagation of this plant, all the varieties, as before noticed, are propagated with great facility by the off-sets or suckers issuing from the lower part of the plant and base of the fruit, as well as by the crown or leafy tuft that decorate the top of it, all of

which suckers, off-sets, and crowns, though devoid of roots when separated from the plant, that being planted singly in small pots of light rich compost, plunged in the bark hot-bed in the stove, &c. as hereafter directed, readily emit fibres, and grow freely, and, as already noticed, they, after two, or, at most, three years growth, produce ripe fruit, equal in size and quality to that of their respective parent-plants, observing that the same individual plant produces fruit but once; so that after they have fruited and produced a supply of suckers for encrease, which is commonly at the time of fruiting, they are good for little afterwards, except as stools to produce a few more suckers; hence it is apparent the necessity there is of raising an annual succession of fresh plants for fruiting, by the above means of suckers and crowns.

Each plant generally yields from two or three to five or six suckers at a time, but rarely more than one crown upon each fruit.

The season for propagating, both by suckers and crowns, is according to the time the plants and fruit produce them, which is principally July, August, and September, according as the fruit ripens, though the plants will grow at almost any time, observing, however, that both suckers and crowns are always fit to be taken off for propagation when the fruit is ripe, and not sooner; and as to the suckers, it is a sign of perfection when they appear brownish at bottom; they are to be slipped or drawn off carefully with the hand, not cut; the crown at top of the fruit is to be taken off also with a gentle twist; but this latter is not to be done till the fruit is served at table. When they are taken off, both the suckers and crowns should be divested of a few of the lower leaves at the bottom, where they are to strike root, then laid or hung up in a dry part of the house or stove four or five days, that the wound or moist part of the base, where they adhered to the plant or fruit, may heal and dry up before they are planted, otherwise they would be apt to rot; but in some of the stools you will often find suckers which assume a brown colour at the bottom, as above hinted, and forming little knobs round the edge, which are the embryos of future roots; these suckers being ripe, or having had their full growth on the mother-plant, do not require to be so much dried as those which appear greener, and may even be planted directly, or, at least, taken off one day and planted the next; but the crowns of those fruit which do

not ripen till late in September or October, require to be dried more than those before-mentioned, and if suckers of those plants that produce their fruit later do not appear brownish at bottom, it is adviseable to suffer them to remain upon the stools till March following, for they are very apt to rot at bottom, not only when taken off very succulent, but also when taken off later than October.

We have commonly the greatest quantity of crowns and suckers from the beginning of August to the middle of September.

As to the mother-plants or old stools, if you are disposed to have as great an encrease of young plants as possible, the stool, after the fruit is gathered, and the suckers taken off, may be trimmed, i. e. cut down all the leaves near the bottom, and then plunge the pots directly in a hot-bed of tan or dung under frame and glasses, and let them be duly watered, they will soon after produce another supply of suckers, though those of the first production are rather preferable.

Likewise in cases, when the plants produce ripe fruit and no suckers from the bottom at that time, as soon as the fruit is cut, trim the leaves of the old stools, as above directed, and plunge them in a hot-bed of brisk heat; it will dispose them soon to send forth several suckers.

Method of planting, and their Management in the Nursery stove, &c.

To proceed to the manner of planting the crowns and suckers, and general culture the first year, to prepare them for the fruiting-stove, observe as follows.

Having the bark-pit in the nursery-stove or frame, &c. filled with bark, see BARK-BEDS, and of a proper brisk temperature of heat, for the reception of crowns, as they are taken immediately from the mother-plant, at the times and manner above-mentioned, and having the proper compost in which to plant them, pots, and every other requisite in readiness as they shall be wanted, these young plants then, according as they are fit to be taken from the parent-plant, are to be planted singly in small pots of the size called forty-eighths, see POTS, which, at the time of planting, are to be filled with the aforefaid compost or mould, taking previous care to put a shell or piece of tile over the hole at bottom of each pot, to keep the mould hollow, that the water given the plants may pass off freely; the pots being thus filled, one plant, i. e. crown or sucker, is to be planted in each pot, in doing of

which, be cautious not to plant them too deep, for the earth to get between their leaves, neither should they be planted too shallow, for so they would be liable to be displaced by watering, or doing any other necessary culture, observing to press the earth close about each plant.

According as the plants are thus potted, they are to be directly plunged in the bark-bed of your succession-stove or nursery-frame, &c. above described, observing that the bed be previously arrived to a due degree of moderate heat, and in which the plants are to be arranged according to their different sizes, placing the largest next the back-part, and the smaller in front, and the others in proportion; that being thus regularly disposed, it will add to the beauty of them, and every single plant will more easily receive an equal benefit of the sun, being careful to plunge each pot up to the rim in the bark.

As soon as they are plunged give them a gentle watering, and, if the weather is sunny and hot, shade them moderately in the heat of the day, till they are firmly rooted.

Having thus planted and plunged the plants in the bark-bed, &c. they will in a week or two strike root and begin to grow, when air must be pretty freely admitted; for at this period it is adviseable to promote but a moderate temperature of heat, that is, not to encrease it considerably by keeping the stove or frame too close while the heat of the bark-bed is strong, which would not only draw up a vehement heat in the bed at first, and force the young plants too much in growth, but, by being too closely confined, would draw them up weak, with long, feeble, whitish, sickly leaves: fresh air must therefore, at this time, be daily admitted, at least at all opportunities, when the days are hot and calm, by shoving or tilting the glasses a little open, which must always be proportioned in a judicious manner, for there are no precise rules to be given for it; but by making use of your own observation and experience, added to these directions, you will soon attain a due knowledge in this point. From about nine or ten, to four or five o'clock, is the proper time of day for the admission of air.

Waterings also is requisite, though very moderately, about once a week, especially until the plants begin to grow, when they may be watered more freely, which in fine warm weather should be sprinkled all over their leaves.

As

As the winter advances, be careful that the bark-bed, wherein these young plants are now plunged, uphold a constant temperature of heat, which is readily promoted by forking up the bark once or twice during this season, according as the heat shall decline; likewise keep the internal air of due temperature, by the aid of occasional moderate fires on nights, provided the department is furnished with flues, or, in default of which, by linings of hot dung against the outsides: fresh air must also be admitted from without judiciously, at all favourable opportunities, in sunny calm days, by sliding or tilting some of the glasses or sashes a little open; and moderate waterings is necessary about once a week, especially if the plants are in a stove or pit where fires are made; in other cases it must be applied seldomer, and very sparingly.

In respect to the bark bed, it generally supports a good temperament of heat till January or February, when, if the heat is found much abated, take up all the pots, and with a fork stir up the bark, as before observed, quite to the bottom, plunging the pots again directly, and this will promote a fresh fermentation, and greatly revive the heat, so as to maintain a due temperature the remainder of the winter.

And as to the fire-heat above-noticed, for warming the internal air, observe, that, if the plants are in the nursery stove or succession-house, or any other department, having flues for making fires, it is proper to begin to make moderate ones on nights towards the middle of November, or a little sooner or later, as the frost or other very cold or dark foggy weather shall render it necessary, being cautious never to make the fires too strong for these young plants, lest, by occasioning them to shoot too fast, it force them into trifling fruit the same winter, or ensuing spring or summer, which would be a great disappointment in respect to having proper-sized plants at the due time for the fruiting-stove; for if once these young plants draw up with long leaves, appearing white at heart, it is generally the signs of a too forward growth, and the consequence of their untimely fruiting; therefore never be too eager in forwarding their growth at this season.

In severe weather the glasses of the stove should be defended on nights with the proper covers, either of thick canvas, oil-cloths, or tarpaulin, let down by a roll and pulleys, or by shutters or mats.

Where these young plants are wintered in any detached bark-pit, or any kind of frame devoid of flues for having fires, I advise, in this case, when the winter advances, that the pit or deep frame, wherein the bark-bed is made, be lined around on the outside with hot dung, as practised to cucumber or melon-beds, quite from the bottom to the height of the internal bark-bed: on top of the lining lay old hay, fern, or other similar dry litter, continuing either of which materials from the top of the lining to that of the frame all around, which will preserve the heat of the linings the longer, and prevent the frost from penetrating the sides of the frame, observing, that when the lining declines its heat, remove the litter, and add a sufficient quantity of fresh dung on top of the former to the height of the frame; or, if the heat is considerably abated, stir up the whole with a fork, old and new together, to the above height, which will renew the heat quite from the bottom; and this stirring or turning over the linings, with the occasional addition of fresh dung, in lieu of such that becomes exhausted, is to be repeated as often as it shall appear necessary during the winter or continuance of cold weather, which will not only communicate its heat to the bark-bed, but assist greatly in warming the internal air of the frame, observing also to cover the glasses every night and severe weather, and give but very little water to the plants in this department during winter.

Having in either of the above departments conducted the plants safe through the winter, it now remains to give directions concerning their spring culture.

As to their spring culture, the necessary care of preserving heat in the bed, and internal air, with the aids of fresh air and water, as already directed, is still to be observed with strict attention; for it is of importance to remark, that from the month of March until September, is the principal growing season of these plants, so must begin to encourage it as much as possible, though by no means force them; but that when there is a good heat in the bed, indulge them freely with fresh air, and refreshments of water, by the rules already laid down, and hereafter directed.

At this season the plants, for one thing, require their first shifting into pots a size larger, and the bark-bed to be stirred up again, and refreshed with about one third of new tan.

This first shifting may be performed any time in April, though about the middle of that month is a very good time for that work, and the proper sized pots are those called thirty-twos, see POTS. The proper time being arrived, and the pots and proper quantity of compost mould brought ready, proceed to take up the plants out of the bark-bed, and turn each singly out of its present pot, with the ball of earth entire around its roots, unless any appear very unhealthy, or any ways defective, when it is eligible to shake the earth from the roots, and trim off all the long fibres and other parts that appear not alive; also decayed leaves on the plants in general must be stripped off, not cut, then, having put a piece of tyle or oyster-shell over the holes at bottom of each pot, put in a little fresh compost, and on this place your plant, and fill up around the ball or root with more new mould almost to the brim of the pot, pressing the earth moderately firm about the body of the plant; and when the whole is thus shifted, directly prepare to plunge them again in the same bed; previous to which observe, as above, to add about one third, at least, of new tan to the old, or as much as will sufficiently raise the bed as much as it has sunk since autumn, previously clearing away any very crumbly or exhausted earthy stuff at top or outsides; then, having filled up the pit to the usual height with the new bark, immediately proceed to work the whole, old and new up together, with a fork, see BARK-BED, and directly plunge the plants as before, the tallest at back, continuing the lowest gradually to the front; and as soon as the whole is thus plunged, give a moderate watering all over the leaves and mould of the pots, to cleanse the plants, and settle the new earth close about their roots.

The plants having thus had their first shifting, and the bark-bed its spring renewal by a little new tan and fresh forking up, the principal future culture during summer is the necessary supply of fresh air and water; for the bark-bed will now maintain a proper heat till towards autumn, or time the plants require shifting again.

As the summer comes on, the plants must be indulged more freely with air and water; air must be admitted every day, whensoever the weather permits, by opening some of the lights, more or less, which should be done the most freely when the days are sunny and the wind quiet, and in July and August, if

the weather is very hot, the plants should be permitted to enjoy a very large share air, even so much as to be sometimes almost fully exposed in the middle of such days; for as they will now grow freely, if they are too closely confined they will draw up long and tender, and become feeble and less able to produce fruit in full perfection of size and flavour; and likewise, by too close confinement in summer, they will be in danger of going into fruit early in winter. Water during this season in warm sunny weather is necessary, in moderate quantities about twice a week, applying it in a morning until June; and during the hot months of June, July, and August, an evening is the most eligible time, sprinkling the water occasionally all over their leaves; which works of admitting fresh air, and giving water, is the principal culture necessary to these plants in summer, until the time of their second shifting into larger pots in August.

Observe, however, if the bark-bed is much crowded with plants, and that by the beginning of July they have advanced considerably in growth, it would be of much advantage to remove some of the smallest plants in their pots into a bark-bed, under any common frame, till October; so re-plunge the larger ones at a more eligible distance in their present department, which is the most necessary culture to encourage them to bottom well.

In regard to their second shifting, the plants in general will require it in August, at which time a quantity of the strongest plants are to be shifted into proper sized pots, wherein they are finally to remain to produce their fruit.

This second shifting is to be performed about the beginning or middle of August; the pots proper for their reception now is called twenty-fours, but not larger than sixteen for the stoutest plants: in the execution of this work observe to turn the plants out of their present pots with the balls of earth entire about their roots, and may carefully trim off a little of the outside mould, as also some of the extreme fibres of the roots on the outside of the ball, still preserving the ball of earth about them; then having tiled or shelled the holes of the new pots, and put some fresh earth at bottom, to raise the plant to its due height, place the plant thereon, and fill up the pot around the ball with more compost almost to the top, and when they are all shifted, stir up the bark-bed to enliven the heat, and instantly plunge the pots again in the order of arrangement before directed, and give

give a moderate watering all over the plants: here they may remain six weeks or two months, or longer; for if the bark-bed at this time of shifting is well forked up to the bottom, it will uphold a heat proper to support the plants in a growing state till October, when most of them will have obtained a large size, and the fruiting-stove is to be got ready for the reception of the largest that appear capable of fruiting in perfection the ensuing year: in the mean time be careful, after this second shifting, to continue the admission of a due portion of fresh air daily, to strengthen their growth, to dispose them to produce handsome fruit at the due time; supplying them also with gentle refreshments of water once or twice a week, according to the temperature of the season.

Removing them to the Fruiting-stove, and Culture there.

Towards the end of September the above plants in the nursery-stove or succession department will be grown to a considerable size, when the fruiting-stove, &c. must be got ready, and its bark-pit filled with entire fresh tan, for the reception of the largest plants; and such as have not yet acquired due strength for fruiting in perfection next year, may be permitted to have another year's growth in the succession-stove.

If the fruiting stove is now occupied with plants in fruit, the succession-plants cannot be moved thither till the fruit is mostly all cut, which for the general part is pretty well cleared by October or beginning of November, at which time a sufficient quantity of fresh bark or tan must be procured from the tanner's to fill the bark-pit of this stove, for the bark bed must be always renewed annually almost entirely with fresh tan at this season, at same time previously screening all the old tan to separate the larger from the small exhausted parts, and all the small earthy stuff that passes through the screen taken away, and levelling the other along the bottom, provide as much new tan as, with this, will fill up the pit to the proper height.

As to the choice of the new bark, it should be fresh, i. e. having been but shortly thrown out of the tan-vats, and rather large than small, for the latter soon becomes earthy, and loses its fermentation: when it is brought from the tanner's, it is frequently wet and unfit for immediate use; let it therefore be spread on level ground to dry a day or two,

then either cast it in an heap to acquire a proper warmth, or put it immediately into its destined pit in the stove, upon the remaining old tan, raising it three or four inches higher than the kirk at top, to allow for settling, forking up the old and new together, so suffering the whole to remain a week or ten days, to acquire a due temperature for the reception of the plants from the succession-stove; for they must not be plunged in it before it is capable of imparting a proper warmth to the mould in the pots.

Having thus prepared the pit of this stove, as above, with good fresh bark, and it has obtained the due degree of heat, then immediately bring your largest plants from the succession-stove in their pots, and plunge them with the same regularity I before advised, and allow them room, that they may bottom well, for this is of importance in respect to their producing large fruit: the plants being plunged, it is proper the next day, or as soon as the bed has communicated a proper warmth to the earth in the pots, to give them a moderate watering, both to the pots and all over the leaves, which will be a considerable refreshment to the plants.

They being now placed in the fruiting-stove are called fruiting plants.

Their culture in this department, i. e. the fruiting-stove, differs little from that in their former repository.

All winter the internal air of the stove must be sufficiently supported by the aid of fires on nights, and severe frosty weather. As to the heat of the bark-bed, it will support a due temperature till February, when forking it over will revive it for two months longer. Fresh air during this season must still be admitted with discretion at favourable occasions in sunny mild days, and moderate waterings will be needful about once a week.

With respect to the time to begin to make the fires, is some time in November, either sooner or later in that month, according as the cold advances, for we must be very careful to observe this as soon as severe or very foggy or cold wet weather renders it necessary; but unless severe frosts happen, gentle fires only on nights should be made until the beginning of January, when they should be gradually increased more brisker, in order to prepare the plants for shewing their fruit in February or beginning of March, being always careful to regulate your winter's heat by the thermometer, see THERMOMETER; observing the fires
are

to be made principally on nights, except in severe or very wet or foggy damp weather, then it is proper to continue them also moderately in a morning.

In very severe weather it is also eligible to cover the glasses on nights with such covers as the stove is furnished, either by large thick canvas cloths or tarpaulins on rolls, to let down and up by pullies; or with large mats, or shutters; but the first-mentioned is the most ready covering for the top glasses, see HOT-HOUSE; though many use no other covering for their stoves, where fires can be made, than nailing strong mats at top on nights in very severe weather; also occasionally against the front and end glasses.

During this season give air discretionally in fine mild sunny days, from ten till about three o'clock, as favourable opportunities shall then offer.

Give also moderate waterings about once a week, and not much over their leaves at this time of year, using the tin pipe hereafter mentioned.

Towards spring, when the plants begin to shew fruit, be still careful to promote a due degree of heat in the bark-bed, and continue the fires regularly on nights, and give air and necessary waterings. If, in January or February, as above hinted, the bark-bed decreases much in its heat, fork it up, as directed for the succession-plants, which will renew the fermentation, and continue it in fine order until April, when a little new tan must be added, and the whole again well stirred up together to the bottom.

In the beginning of April therefore, prepare to add some new tan, and stir up the bark-bed again, to promote such a durable heat as will carry the plants through the summer, and till the maturity of the fruit now advancing in growth: to do this the more effectually, provide about one third of the pit full, or a little more or less, of new tan, prepared, as before, in making the bed; and after taking up all the pots of plants, throw this in upon the old tan, filling up the pit to the full height, then fork the whole up to the bottom, mixing the old and new well together; this done, level the top, and directly re-plunge the plants, and the effect of this operation will soon appear in the growth of the fruit; for after this fruit begins to advance, it is good culture to promote a good heat in the bed, as well as sufficiently to preserve a constant and proper temperature of internal

air, according to the degrees of heat marked on the thermometer, that you may more freely apply the necessary aids of fresh air and water; and that by proportioning heat, air, and water, depends the whole success of having large and well-flavoured Pine-Apples.

One caution in respect to watering is, that after the fruit begins to appear, I advise not to water too freely over the leaves, but more especially when they are in bloom, lest you wash off the farina of the antheræ, before it has sufficiently performed its fecundating function, and thereby prevent some of the knobs or tubercles from swelling in a due manner, which would render the fruit unsightly; therefore, in watering at this period of their growth, it is proper to use the tin pipe hereafter mentioned, which is also very convenient for watering at all other times, and more especially in winter, when the plants should never be so much wetted as to occasion water to stand in their hearts.

As the summer and warm weather advances, gradually decrease the strength and use of fire heat, and by degrees use it only occasionally, so as to leave it wholly off in May.

Continue during summer to admit fresh air daily into the stove, by sliding the front or top lights more or less open, according to the power of the sun's heat, still observing, that from about eight or nine in the morning, till four or five in the evening, is the proper time for doing this: also continue to give water freely all summer, about twice a week, at least, in hot weather, performing it either in a morning or an evening, which, after the blossom of the fruit is past, and it advances in magnitude, may be given in occasional refreshments all over their leaves, as this will promote a lively appearance in the plants, and encourage the free growth of the advancing fruit; for the heat of the bark-bed being promoted by the means advised to be practised in April, if you are careful during the hot weather to indulge the plants freely with fresh air and refreshments of water, agreeable to the preceding rules, the fruit will encrease freely in bulk, and advance fast to perfection, so as those which appeared early in spring will probably arrive to maturity in June or July.

They, however, in respect to the times of ripening, generally come dropping in from June or July to October or November, but are commonly in greatest perfection in August and September.

The

The first sign of perfection in most sorts is, their assuming a singularly beautiful golden yellow, though some discover different tints peculiar to them; but the most certain sign of full growth and ripeness in this fruit, is its delightful fragrance: observe therefore these tokens of perfection, and let the fruit be gathered before it becomes soft; for it would then be greatly diminished in its perfume and delicate poignancy of flavour.

The manner of gathering this fruit is, to cut it from the plant with several inches of the stalk, preserving also its crown of leaves at top.

To have it eat in the highest perfection of flavour, it should be cut in a morning before nine o'clock, and laid in a cool dry place till dinner-time, or till wanted, but its juice is always more poignant and rich when eaten the same or next day, though they will keep a week or longer, if required upon any particular occasion.

It is always served to table with its crown of leaves on, and when the fruit is to be eaten, the crown is twisted off and reserved for planting, to become a new plant, which, in its turn, produces a fresh fruit, as well as suckers, for future propagation.

If too many of these fruit are like to arrive to maturity together, their ripening may be retarded by removing some of them to one end of the stove by themselves, and so shade the glasses with mats in sunny days.

As to the old plants, after the fruit is gathered, they bear no more, so are only fit for stools to produce suckers, having their leaves trimmed down close, and plunged in the bark-bed, or any other brisk hot-bed, as we have before directed.

Necessary Observations.

In respect to the tin pipe before recommended to be used occasionally in watering these plants, it is extremely useful and convenient, for the more ready conducting the water, in the quantity intended, to any particular plant in any part of the bark bed: its dimensions may be six feet long, an inch and half diameter at the upper end, the other about half an inch, though it may be of two different joints to lengthen or shorten at pleasure; at the largest end should be a kind of funnel, either fixed, or to take off and on occasionally, to receive the water from a watering pot. By the assistance of such a pipe, the water is readily conveyed to all the plants separately in any quantity, without pouring

any into the hearts of them when not intended, or without wetting the bark-bed more than what is necessarily applied to moisten the earth in the pots, &c. This pipe should be particularly used in winter; also occasionally in spring during the bloom of the fruit.

Soft water should always be used for watering these plants, either that of a river, pond, or rain water, being careful in applying this article never to give it in too great quantities, to wet the mould considerably, especially in winter.

In winter it is proper to have a cistern, or some other conveniency placed in the stove to contain water, that the chill may be a little taken off previous to watering the plants therewith.

With regard to the fuel for making the fires in the stoves, several sorts are used.

The best fuel for this use is coal, which makes the most ardent, regular, and durable fires of any other materials whatever, and therefore, where it can be obtained at a moderate expence, I should particularly recommend it for this purpose: but, in default of coal, wood is next to be preferred, and the larger the principal part is, the better for the duration of the fires. Next to wood is ground-peat and turf, but these are soon exhausted, unless the fire-place is purposely constructed, see HOT-HOUSE. There is a sort of fuel by some used, to be had at the tan-yards, made of old tan, &c. into square lumps, which is also called peat; but all these are inferior to coal, though, where this article is scarce, one or other of these must suffice.

It is to be observed, the fires in each department are to be made chiefly from November until April or beginning of May, and should be made every evening about four, five, or six o'clock, which should be attended twice or thrice till bed-time, so as to warm the flues sufficiently to support a due temperature in the air of the stove till morning, when, in very severe frost, and very wet or foggy damp weather, a moderate fire should also be made, but in mild dry weather none is necessary at that time of day.

To regulate you in regard to the strength of the fires, and proper times to make them, it is proper to have a good thermometer always hung up in the middle of the stove, having the proper degrees of heat marked *Ananas*, never permitting it to be more than five or six degrees above, nor less than that below the mark.

Raisins

Raising these Plants without Stoves and Fire-heat.

We having occasionally observed, that it was possible to raise and fruit this favourite plant without the aid of stoves or fire-heat, by the heat of hot-beds only, under proper frames: the hot-beds for this purpose are either of tanner's-bark, assisted by occasional dung linings, or may be composed of dung, having a foot of tan or saw-dust at top, in which to plunge the pots, and assisted also by proper linings of dung.

This method, however, though apparently considerably the least expensive, is attended with much more trouble and uncertainty than the stove culture already treated on, having the constant aid of bark hot-beds, and fire-heat in winter.

However, for the advantage of those who cannot easily obtain a plenty of tanner's-bark, and who have no mind to go to the expence of erecting stoves, and burning fire six months in the year, and are disposed to make trial of raising Pines by the above methods, we shall proceed to give some hints for the manner of effecting it, though we do not recommend it as a generally successful practice.

I before noticed in the stove culture, that the crowns and suckers immediately from the mother-plant may be readily struck, i. e. rooted, and set to growing in a tan or dung hot-bed, under a common cucumber or melon-frame; the dung-bed having ten or twelve inches depth of tan at top, or, in default thereof, saw-dust, but tan is best, in which to plunge the pots containing the plants, and by shifting them into one or two new such substantial hot-beds, with the addition of occasional linings of the same material, the plants may be continued there all winter, or even until the following autumn, provided the frames were of due depth for the plants to grow.

But for this purpose it is proper to be provided with two different sized wood-frames, furnished with suitable glass lights, particularly for this method of culture, one by way of a nursery-frame, to strike and rear the plants, and another of a greater depth, for fruiting them, as advised for the stoves.

The first of these frames being intended as a nursery-frame for rearing the crowns and suckers, its dimensions may be ten or twelve feet long, six wide, three and a half deep at back, and two and half in front, with three sliding lights at top, and if half the depth of the front was glazed it would be an advan-

tage; which frame, at the proper time for planting the crowns and suckers, i. e. August and September, is placed upon a bark-bed, or substantial dung hot bed covered with tan, to plunge the pots in, or, for want of that, saw-dust, but the former is greatly preferable; observing, if you use dung-beds, three or four different new ones, with occasional linings, as hereafter described, will be required to support the growth of the above young plants a year, or till fit for the fruiting-frame, being careful to supply them at due times with fresh air and water, as directed in the stove-culture, though, in this place, as having no fires to dry the damps, they must be very sparingly watered in winter.

The fruiting-frame being intended to fruit the plants, must be deeper than the former, and the whole front and ends, as well as the top, glazed, and may be made to place on the top of a raised pit of the same width and length, and three feet and half deep, formed either by a wall of brick or strong inch planking, in which to make the hot-bed; which pit is more particularly eligible, if you intend to have a bark hot-bed: but as to the dimensions of the frame itself, it may be twelve feet long, six in width, four and half deep in the back, and two and a half depth in front, having three sliding sashes in the front, and one at each end, and the whole covered at top with three glass lights to shove up and down; the glazing at top done imbricatum, as directed for the hot-house, see HOT-HOUSE; having also a painted canvas or old sail-cloth on a roll, or some other covering, to use on nights, to defend the glasses. As to the pit, it may be sunk eighteen inches, if dry ground, allowing width and length enough to build a nine-inch brick wall on every side, to form the cavity of the pit of due dimensions to receive the frame at top of it, which wall is to be three feet six inches high from the bottom; or, if the back part was of inch deal, would be more convenient to admit the benefit of lining, to renew the heat; or, instead of brick, a pit formed entirely of post and planking; or a moveable wood one would answer the same purpose: upon this brick pit, or wood frame, the glass frame of the aforesaid dimensions is to be placed, and the hot-bed is to be made in the pit to its full depth. To render it still more convenient, one such frame might be made to serve two pits, making it to slide from one to the other, having a partition between; and when one bed has declined its heat, make

make a fresh one in the spare pit, so slide the frame over it, and move the plants therein; the utility of this will be very obvious in practice, especially if the hot-bed is composed of dung, which will require renewing three or four times in the course of the year.

This is the general construction of the fruiting-frame.

In the pit of this frame a hot-bed of tan, or of dung covered with tan, &c. before hinted, is to be made the latter end of September, for the reception of the plants from the nursery frame, observing, if the bed is of dung, make it substantial enough for the top to be within eight or ten inches of the top of the pit when fully settled, upon this lay the tan or saw-dust above-mentioned, and in which plunge the plants in the same order as in the hot-house, giving fresh air and water, agreeable to the directions in the stove-culture, but being still careful to water with great moderation in these frames during winter, and cover the glasses every night.

If the hot-bed of this frame is of tanner's-bark, it, by the aid of dung linings at back of the pit, will support a due temperature till February, then stirring it up, as directed in the stoves, renews the heat till April, and then, by adding a little new tan, and another forking up, and occasional linings, it will support a sufficient heat to bring the fruit to maturity; but if the bed is of dung covered with tan, &c. two new beds, with occasional linings, will be requisite to carry the plants through the winter; that is, one bed when the plants are first placed in the frame in September, and another new one in the middle or end of December, and about two more to bring the fruit to perfection: hence the utility appears of having two pits, as you can then conveniently make a new bed in the spare-pit in due time, to acquire a proper temperature to be ready to receive the plants in their pots immediately from the declined hot-bed, at the same time shoving the frame from thence over the new one. Observe, in the mean time, during winter, that as soon as you perceive the heat of the bed, either that of tan or dung, begins to abate, you begin to line the back-part of the pit and frame on the outside with hot dung, both to enliven the heat of the bed, and assist in warming the internal air of the frame: this lining should be laid three feet wide, at least, at bottom, and a little sloping at top, that the wet may pass off freely; neither should it be raised to the

full height at first, but a little at a time, as the frost or severe weather increase, till at last it become as high as the whole back-part of the pit and frame together, continuing it also, as the cold advances, round the ends and front of the pit, at each time laying hay, fern, or other dry litter upon the lining, which preserves the heat the longer, and prevents the frost from penetrating the frame; and by thus gradually lining the beds, as the severity of the weather shall demand, it will maintain the due temperature of heat much longer, and more regular than if the whole quantity was to be added at once; observing, when the heat of these linings is much decreased, it must be renewed by the addition of some fresh dung, and the whole forked over to the bottom, which is to be repeated as you shall see occasion.

By observing the above directions in the management of the hot-bed, and giving fresh air at all due opportunities consistent with the rules laid down in the stove culture, and moderate waterings at times in fine sunny weather, the plants will shew fruit in February or March, which will ripen at the usual time in as good perfection as can be expected.

BROOMS, for the use of gardens.

In pleasure-grounds Brooms are almost daily wanted, especially in summer, and the best sorts for this use are those of Birch, made of the finest brush-wood, that will not soon become stubbed; nor should they be made very large and clumsy, which would tear up and deface the grass and gravel.

Heath Brooms are sometimes used, but these are not near so good as Birch ones for gardens.

In default of Birch, Beech-Brooms are also sometimes used, which being made flat, spreading, and light, they will answer tolerably for sweeping the mowings of short grass, and fallen leaves off grass-ground; but are not so fit for use on fine gravel, except lightly to whisk it from fallen leaves.

BRUNSFELSIA.

There is but one species, a shrubby exotic of the stove, garnished with simple leaves and funnel-shaped flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is monophyllous, bell-shaped, five-parted, and permanent. **COROLLA**, a funnel-shaped petal, the tube long, but spreading and five-parted at top. **STAMINA**, five filaments inserted into the corolla, and

and oblong antheræ. **PISTILLUM**, a roundish germen, slender style, and thick stigma. **PERICARPIUM**, a globular berry of one cell, having numerous seeds.

The species is,

BRUNSFELSIA Americana.

American Brunfelsia.] Brunfelsia with a woody, branching, rough stem six or eight feet high, garnished with oblong, entire leaves on foot-stalks, and large whitish flowers by threes or fours at the ends of the branches, succeeded by round, saffron-coloured, soft fruit.

This plant may be raised here from seeds in the spring, sown in pots, and plunged in a bark-bed; and may also be propagated by cuttings in the same season planted in pots, plunging them also in a bark-bed or other hot-bed under glasses; and the plants must always remain in the stove.

BRYONIA, the White Briony, or Wild White Vine.

The plants are herbaceous climbers, consisting of annuals and perennials; of the latter are about two species that merit notice by way of variety, one a hardy plant of English growth, the other an exotic that requires shelter in winter.

Class and order, *Monoecia Syngenesia.*

Characters.] **CALIX**, male and female flowers apart on the same plant, having a monophyllous bell-shaped cup, five-parted at top. **COROLLA** is bell-shaped, five-parted, and adheres to the calix. **STAMINA**, the male flowers have three short filaments, two of which have double antheræ, the other one. **PISTILLUM**, in the female flowers a germen under the corolla, a trifid patent style, and spreading emarginated stigma. **PERICARPIUM**, a smooth oval berry, having oval seeds adhering to the skin.

¹**BRYONIA Alba.**

Common White Briony.] Briony with a large, thick, fleshy, white root, sending up annually very long climbing stalks and branches, garnished with large, palmated, rough, callous leaves, and numerous clusters of white flowers in May and June, succeeded by bright red berries.

²**BRYONIA Africana.**

African Tuberous-rooted Briony.] Briony with a large tuberous root, sending up annually several slender rambling stalks, having palmated, five-parted, smooth leaves, their lobes cut and pinnatifid, and clusters of greenish flowers, sometimes succeeded by berries having ripe seed.

Both the species have perennial roots, but their stalks die annually in autumn.

The *Bryonia Alba* is a wild plant of England, inhabiting dry banks under hedges, where the roots acquire a monstrous size, sending up strong climbing branches, running many feet long, and attach themselves to the bushes, or the first thing they encounter in their progress, and make a singular appearance, but it is seldom admitted in gardens, though a plant or two for variety merits a place in large grounds as climbers.

The root of this species is also in great request for medical uses.

Its propagation is easily effected by sowing the berries in spring in a dry light soil where the plants are to remain, and when they come up, thin them to a considerable distance.

The African sort must be kept in pots, to be moved under shelter of a frame or greenhouse in winter.

It is raised by seeds in a hot-bed in spring.

BRYONA NIGRA. See **TAMUS**.

BUBON, Macedonian Parsley.

This genus comprises herbaceous and shrubby plants; the former have little merit, but of the latter are two species proper to be admitted in the green-house collection.

Class and order, *Pentandria Digynia.*

Characters.] **CALIX**, umbelliferous flowers, having a five-leaved involucre; the general umbel composed of about ten smaller; each smaller one of fifteen or twenty rays, and a small permanent calix to each floret. **COROLLA**, each floret of the umbel consists of five spear-shaped inflexed petals. **STAMINA**, five filaments and simple antheræ. **PISTILLUM**, an oval germen below the corolla, two reflexed styles, and blunt stigmas. **PERICARPIUM**, none; an oval two-parted fruit, having two seeds.

The species of note are,

¹**BUBON Macedonicum.**

Macedonian Herbaceous Bubon.] Bubon with many compound leaves from the root, on longish foot-stalks, each leaf composed of many oval rhomb-shaped indented lobes, and in the midst a branching flower-stalk about fifteen inches high, having all the branches terminated by white umbels in July, and ripe seed in autumn.

²**BUBON Galbanum.**

Shrubby Galbanum-bearing Bubon.] Bubon with an erect woody-stalk growing eight or ten feet high, having a purplish-coloured powdered bark, leaves at the joints, composed

posed of many rhomb-shaped, indented, smooth folioles, and the stalks surmounted by yellow umbels in September, but no seeds in England.

¹*BUBON Gummiferum.*

Shrubby Gummiferous Bubon.] Bubon with an erect woody stem, garnished below with leaves composed of many rhomboid, sawed, smooth folioles, those above pinnatifid, narrow, and tridentate, and the stalks crowned by white umbels in September, but rarely any seeds here.

These two shrubby kinds, on breaking any part of them, impart a gummy cream-coloured matter, of which is prepared the *Galbanum* of the shops.

The *Bubon Macedonicum* is cultivated in some gardens for variety. It is propagated by seeds in spring, sown in a bed of common earth, and in autumn transplant the plants into a warm border, and some in pots for occasional shelter. In about three years they will flower and perfect seeds, then totally perish.

The two shrubby Bubons are natives of Africa, and require shelter of a green-house here in winter, so must always be cultivated in pots.

They are raised from seed procured from Africa, sowing it as soon as possible in pots of light earth, to be occasionally sheltered from frost, and in spring plunge them in a hot-bed, where the plants will rise, and be fit to plant in separate small pots in May or June, plunging them also in a moderate hot-bed, and supply them with occasional shade, water, and fresh air, to which fully expose them in July, and in October remove them to the green-house.

BUDDLEJA, Buddleja.

It comprises two shrubby plants of the hot-house, decorated with simple leaves, and monopetalous flowers in spikes.

Class and order, *Tetrandria Monogynia.*

Characters.] *CALIX* is small, divided into four parts, and permanent. *COROLLA*, a bell-shaped quadrifid petal. *STAMINA*, four short filaments in the divisions of the corolla, and short antheræ. *PISTILLUM*, an oval germen, short style, and blunt stigma. *PERICARPIUM*, an oblong capsule of two cells, and numerous seeds.

The species are,

¹*BUDDLEJA Americana.*

American Buddleja.] Buddleja with a woody whitish stem and opposite branches, growing

eight or ten feet high, garnished with oval, sawed, opposite leaves, downy underneath, and yellow flowers in branching spikes from the ends of the branches.

²*BUDDLEJA Occidentalis.*

Occidental Buddleja.] Buddleja with a woody rustety stem, growing fifteen or eighteen feet high, sending out many slender branches, adorned with spear-shaped, pointed, entire leaves, placed opposite, and large, loose, whorled spikes of white flowers at the end of every branch.

These two plants are of American growth, and preserved here in our stoves for variety.

They are propagated by seeds procured from America, which sow in pots of light earth; plunge them in a hot-bed, and give light waterings thrice a week, and the plants are to be transplanted into separate pots, and placed again in the hot-bed, or in that in the stove, where they must be always continued.

BULBOCODIUM, Mountain-Saffron.

Two species only belong to this genus, small, bulbous-rooted, flowery perennials of the common ground, having funnel-shaped hexapetalous flowers three or four inches high, six stamina, and one style.

The species are,

¹*BULBOCODIUM Serotinum.*

Late-flowering Mountain-Bulbocodium, with narrow rush-like leaves.

²*BULBOCODIUM Vernum.*

Spring-flowering Spanish Bulbocodium, with spear-shaped concave leaves.

They may be propagated by off sets at the decay of the flower and leaf every second or third year; also by sowing the seed in pots in autumn, sheltering them in a frame from frost, and the plants will appear in spring, which, at the decay of the leaves, may be taken up for planting in the borders in October, where they will flower the year following.

BULBUS, a Bulb, or Bulbous root, *Radix Bulbosa*; or, according to naturalists, a kind of great bud produced under-ground upon the crown of the root of certain herbaceous perennials, such as the onion, lily, tulip, &c. hence denominated Bulbous-rooted plants.

In Bulbous plants, what we commonly call the root is defined to be only a sort of large bud, composed mostly of the rudiments of leaves, which enclose and secure the embryo of the future shoot of the flower; for, at the lower part of this bulb may be observed a fleshy knob or tubercle, from which proceed

proceed a number of fibres attached thereto, is properly speaking the true and genuine root from which the flower-stem immediately rises, and that the upper part or bulb is, as before hinted, in most sorts, partly the remains or rudiments of former leaves, as well as the rudiments of future ones, serving for a certain time as a cradle or nursery, to defend from the injuries of weather the embryo plant, that is, the leaves and future flower-stem in miniature, which, after being repaired a certain number of times annually, the whole bulb and root perishes, not, however, till it has produced from its sides annually several smaller bulbs, off-sets, or suckers, for perpetuating the species; for each sucker becomes an individual, producing flowers and seed like the parent; forms also new suckers, which, in their turn, produce others, and in this manner multiply the species as certainly as the seed: for it is observable, that the remains of the former leaves sink below, and the rudiments of the future ones, forming several coats or rinds, whereof the bulb consists, successively perish and shrink up into so many dry skins, betwixt which, and in their centre, are formed other leaves and rinds, and thus the bulb is perpetuated, till arrived at a certain state of growth.

Bulbous-roots differ essentially from tuberous-roots, which consist of an entire solid fleshy substance, as turnep, potatoe, carrot, radish, &c. See TUBEROUS-ROOTS.

Of Bulbs there are two principal species or kinds, viz. Tunicated Bulbs—Squamous Bulbs.

Their descriptions are,

¹BULBUS TUNICATUS, Tunicated, or Coated Bulbs, composed of several tunics, or coats, closely enfolding each other, as in the *Allium Cepa*, or onion, &c.

²BULBUS SQUAMOSUS, Squamous, or Scaly Bulbs, consisting of many scales, or thin plates, or small oval parts placed over each other imbricatum, i. e. in the manner of scales of fish, or tiles on an house, as in the *Lilium*, or lily.

The above two species of bulbs comprehend some esculents of the kitchen-garden, such as garlick, onions, leeks, shallots, &c. and a numerous train of flowery plants, mostly herbaceous perennials, producing beautiful garden-flowers, and most of them hardy enough to succeed in the beds and borders in the full ground.

The principal Bulbs of the flowery tribe are of the following genera:

Amaryllis, including the Guernsey lily, bella-donna lily, Jacobæa lily, &c.—*Narcissus*, or daffodil, including jonquils—hyacinth—tulip—*fritillaria*, and crown-imperial—*Lily*, including martagons—*ornithogalum*, or star of Bethlehem—*galanthus*, or snow-drop—*leucojum*, or great snow-drop—*scilla*, or sea-onion—*colchicum*—*albuca*, or bastard star of Bethlehem—*muscaria*, or musk and grape hyacinth—*iris*, the bulbous and Persian—*hemmanthus*, or blood-flower—*Allium*, or moly—*crocus*, including spring and autumn kinds—*bulbocodium*—*pancratium*, or sea-daffodil. For the different species and varieties of each sort, see their respective genera.

Most sorts of Bulbous-roots multiply exceedingly by off-sets, by which every particular sort is continued, and new varieties are obtained from seed. See the culture of the respective sorts.

Bulbous-plants for the most part may be said to be perennial, for, although the same individual root exists but for a certain time, some not more than a year after having attained a flowering stalk, others longer, they, previous to their dissolution, afford from their sides a supply of suckers or off-sets to perpetuate the respective kinds; so that, at the end of many years, what is still often considered as the same individual root, is, in reality, another, as to every particle thereof.

All Bulbs renew their leaves and flower-stems annually, and their principal season of flowering is at different times, from March to October, some producing their flowers at one time, and their leaves at another, as in some species of *amaryllis* and *colchicum*; others produce their flowers and leaves together, as the hyacinth, tulip, narcissus, &c. and the leaves and flower-stem of all the sorts perish annually, at a certain period after flowering, at which time the root begins its period of rest, drawing no nourishment from the ground, remaining in that inactive state six weeks or two months; within this period of inactivity of these roots, before they put out new fibres to prepare for the future flower, is the only proper time to remove them, either to separate the off-sets for propagation, or to plant the roots in fresh prepared earth, or remove them to any other part of the garden, or to send to any distance; likewise to reserve the Bulbs out of ground for autumn planting.

B U L

planting, when the beds or borders can be more conveniently prepared again for their reception; for most sorts, taken up at the above-mentioned period of rest, may be kept out of ground several months, even if occasion requires; some sorts from the time the flowers and leaves decay in May, June, or July, until the following spring, as often practised, when intended by spring planting to retard the time of flowering, to obtain a longer succession of bloom, by succeeding that of the autumn plantations.

It is however particularly necessary to take up all the choice kinds of Bulbs annually, to separate the off-sets for encrease, as well as to fresh prepare the earth of the beds and borders, to promote the merit of the succeeding year's bloom; this is particularly proper for the curious tulips, hyacinths, narcissus, &c. as to the more inferior sorts of Bulbs in general, they should also be removed every other year, or as often as their off-sets are considerably encreased in number, which, if permitted to remain so long as to encrease into large bunches, they will cramp each other in growth, and produce but small ill-nourished flowers.

It is also proper to remark, that all Bulbs taken up at the above period of rest in summer, I should advise, where practicable, to plant the principal part again the following autumn, in October or November, as they will flower much stronger than those kept out of ground till spring.

BULBUS CAULINUS, a Cauline, or Stem-Bulb, i. e. Bulbs growing on the stem or stalk, opposed to those before described, which grow only under-ground upon the root.

These Stem-bulbous plants have also a Bulbous root under ground, from which springs the stem that produce the Cauline Bulbs here alluded to, which plants are denominated bulbiferous, or bulb-bearing; of this kind are several species of *Allium*, such as common garlick, rocambole, and several others of that genus, bearing several Bulbs, or small cloves, on the summit of the stem, at the origin of their umbel of flowers, which, being planted, freely grow, become plants, and bear Bulbs as above; so that these kinds of bulbiferous plants are encreased both by the off-sets from the root or main Bulb under-ground, as well as those elevated upon the stem: the same obtains in some species of lily, such as the *Lilium Bulbifera*, the bulb-bearing and fiery lily; also often in ornithogalum, or star of

B U P

Bethlehem, and some other liliaceous plants, which emit bulbs at the wings or angles of the leaves.

By the situation of these kinds of Cauline Bulbs, on different parts of the stem, furnish essential marks for distinguishing certain species.

BUPHTHALMUM, including the *Asteriscus*, or Ox-Eye.

This genus furnishes herbaceous and shrubby plants proper for the embellishment of the pleasure-ground and green-house, all of which are garnished with simple leaves, and compound, radiated, and mostly yellow flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] **CALIX**, compound radiated flower, having an imbricated general cup, enclosing numerous florets. **COROLLA**, many hermaphrodite and female florets; the former compose the disc, the latter the radius. **STAMINA**, in the hermaphrodite florets five filaments, having cylindric antheræ. **PISTILLUM**, in the hermaphrodite florets, an oval germen, single style, and stigma; in the females a double-headed germen, simple style, and two stigmas. **PERICARPIUM**, none; a single naked seed in each floret.

The species of most account are as follow: the first three are hardy herbaceous perennials of the full ground.

¹**BUPHTHALMUM Helianthoides.**

Helianthus-leaved American Ox-Eye.] Buphthalmum with a perennial root, and annual stalks four or five feet high; oval-heart-formed, three-veined, sawed leaves, placed opposite; and the branches terminated by large, radiated, yellow flowers, in leafy cups, appearing in July and August.

²**BUPHTHALMUM Salicifolium.**

Willow-leaved Alpine Ox-Eye.] Buphthalmum with a perennial root, and annual stalks about two feet high; spear-shaped, sawed, hairy leaves, placed alternate; and the branches ending in radiated, bright, yellow flowers, in naked cups, appearing in June, July, and August.

³**BUPHTHALMUM Grandiflorum.**

Smooth Willow-leaved Great-flowered Ox-Eye.] Buphthalmum with perennial roots; annual stalks two feet high; narrow, spear-shaped, smooth, slightly-indented leaves; and radiated yellow flowers, in naked cups, at the end of the branches.

The

The three following are of shrubby growth, and require shelter in winter.

⁴BUPHTHALMUM *Maritimum*.

Maritime Sicilian Ox-Eye.] Bupthalmum with a perennial root; very branching, perennial, firm stalks, about a foot high; wedge-shaped, hairy, alternate leaves; the branches crowned by radiated yellow flowers in blunt leafy cups, having foot-stalks, appearing most part of the year.

⁵BUPHTHALMUM *Frutescens*.

Shrubby Ox-Eye of Jamaica.] Bupthalmum with woody stalks and branches, rising eight or ten feet high, adorned with spear-shaped, silvery, hoary leaves, of very different sizes, placed opposite on foot-stalks, having two teeth near the base of each leaf, and pale yellow flowers in scaly cups from the ends of the branches, appearing from July until October.

Variety.] Shrubby Jamaica Ox-Eye with thick oblong leaves, having no teeth on the foot-stalk.

⁶BUPHTHALMUM *Arborescens*.

Shrubby Bahama Ox-Eye.] Bupthalmum with several shrubby stems directly from the root about a yard high, ligneous below, and succulent above, garnished with spear-shaped, thick, succulent, smooth, green leaves, placed opposite, and bright yellow flowers on longish foot-stalks at the ends of the branches, in July, August, and September.

Variety.] Shrubby Bahama Ox-Eye with hoary leaves.

All these six species are exotics, though the three first are hardy, the other three are tender; all of which flower here very ornamentally in summer and autumn, but rarely any but the three first sorts afford seed in this country.

The first three species being hardy flowering perennials that prosper in any common soil, are proper furniture for the ornament of large gardens, in spacious borders, or in vacant spaces towards the fronts of the shrubbery compartments, where they will effect variety, and appear very ornamental several months in summer.

The fourth sort, *Bupthalmum Maritimum*, or Sea Ox-Eye, requires shelter from frost, so must be cultivated in pots, and in winter placed near a green-house or garden-frame, to have occasional shelter in bad weather.

The fifth and sixths sorts and varieties require constant shelter of a green-house in winter, so must be always continued in pots,

and placed to accompany the exotics of that department.

Propagation of all the Sorts.

The three first herbaceous kinds multiply freely by their roots, and by which they may be propagated abundantly in autumn or spring, either by taking off some slips from the roots, or to take them up, and divide them wholly into several parts, planting the slips in the places where it is designed they shall remain.

They may also be propagated plentifully by seeds, in a bed of common earth, in spring or autumn.

The Maritime sort, and the other two shrubby kinds, are propagated easily by cuttings of their branches, any time from April to July, planting them in pots of light earth, which, if plunged in a moderate hot-bed, will facilitate their rooting greatly, though those planted in June and July will frequently emit roots tolerably well without that assistance, allowing occasional shade and waterings.

After they are struck, and advanced a little in growth, plant them in separate pots, and let them remain in the full air till the end of October, then move them to the places of shelter before-mentioned.

BUPLEURUM, Hare's-Ear, and Shrubby Æthiopian Hartwort.

This genus retains both herbaceous and shrubby plants; the former possess little merit, but of the latter are two or three beautiful evergreen shrubs, one for the shrubbery, the others for the green-house.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, umbelliferous flower, having a many-leaved involucre to the general umbel, and to the smaller umbels but five leaves; the main umbel composed of about ten smaller ones, and scarce any calix to the florets. COROLLA, each floret composed of five whole inflexed petals. STAMINA, five filaments, and roundish antheræ. PISTILLUM, a germen below the corolla, two reflexed styles, and minute stigmas. PERICARPIUM none, a roundish compressed two-parted fruit, having two oblong seeds.

The species that merit culture are,

¹BUPLEURUM *Fruticosum*.

Shrubby Æthiopian Hartwort.] Bupleurum with a shrubby stem, dividing into numerous branches, forming a bushy head five or six feet high, adorned with oblong-oval, entire leaves, of a pale green colour, placed alternate,

B U P

nate, and yellow flowers in umbels at the ends of the branches, in July and August, sometimes succeeded by ripe seeds.

²BUPLEURUM *Difforme*.

Shrubby Difforme-leaved Cape Hare's-Ear.] Bupleurum with a shrubby branching stem, growing five or six feet high, garnished with two-formed leaves, the spring leaves being decomposed of many plane finely-cut lobes, succeeded in summer by others that are long, narrow, rush-like, angular, and trifid, growing in clusters, and greenish flowers in spreading umbels at the ends of the branches in July, succeeded by seeds in autumn.

³BUPLEURUM *Villosum*.

Shrubby Hairy Ethiopian Hare's-Ear.] Bupleurum with a shrubby branching stalk five or six feet high; oblong, indented, hairy leaves, downy below, their base half embrace the stalks; and small umbels of flowers at the ends of the branches in July.

The first of these species have great merit as a hardy evergreen for the shrubbery, though it was formerly retained as a green house plant, being deemed too tender to prosper in the full ground; but experience has proved it to be of a tolerable hardy temperature, so as to succeed in the open air all the year in a dry soil; and being a handsome bushy shrub, makes a fine appearance in the fronts of the shrubbery clumps.

The second and third species being tender, must always be retained in pots, to have shelter of a green-house in winter; so must be allowed a place among the green-house exotics.

Propagation.

All the sorts may be propagated both by seeds and by cuttings.

The seeds may be sown in autumn soon after they are ripe in pots of light mould, placing them in a frame, to have shelter from frost in winter, and in spring plunge them in a hot-bed, particularly the two green-house kinds, which will soon bring up the plants; these are to be innured to the full air, and transplanted into separate small pots, giving shade and occasional waterings all summer; and in October placed in a green-house or frame; and in April following those of the first sort may be planted out in the nursery.

By cuttings they may be raised in spring in pots of light earth, plunging them in a moderate hot-bed, where they will readily take root.

But the common Shrubby Ethiopian Hart wort may also be raised by cuttings in the

B U T

common ground, planted in July, August, or September, and sheltered occasionally from frost during winter; or they may be planted in pots at the above time, and placed in a garden-frame for occasional shelter from frost; and in either method the cuttings will emit roots in the spring, giving water freely all summer, and shelter again in winter; and in spring following plant them out in a sheltered place in the nursery.

BUTOMUS, Flowering Rush, or Water Gladiole.

There is but one species, an herbaceous, flowery, perennial aquatic, of tall growth, crowned by umbellate flowers.

Class and order, *Enneandria Hexagynia*.

Characters.] CALIX, umbellate flowers in a single umbel, having a three-leaved involucre. COROLLA, each floret of the umbel is composed of six roundish concave petals. STAMINA, nine awl-shaped filaments, and double lamellated antheræ. PISTILLUM, six oblong pointed germina, and single stigmata. PERICARPIUM, six oblong pointed capsules, having single cells filled with oblong seeds.

The species is,

BUTOMUS *Umbellatus*.

Umbellated Butomus.] Butomus with a thick, oblong, fibry root, crowned by many long flaggy leaves, and a thick, strong, smooth flower-stalk, from three to five or six feet high, ornamented at top by a large umbellate cluster of flowers, in June and July, succeeded by abundance of seed.

Varieties of this are] White-flowering Butomus—Red-flowered Butomus—Deep-purple-flowered Butomus.

These plants are aquatics, and adorn our river-sides, and other watery places, in most parts of Britain; but as they produce very ornamental flowers, all the varieties merit culture in gardens, accommodated with situations properly adapted for their growth, such as in very moist places, by the sides of any piece of water, rivulet, or any place of copious moisture, where the roots may be mostly in water, particularly any boggy or marshy part, where these and several other of the aquatic tribe may be introduced, which will flourish, and render such places very ornamental.

Their propagation may be effected by seed, or by the roots.

By seed, it may be sowed thick in any watery or boggy place, as above, as soon as it is ripe, and left to nature. By roots, they may be removed any time after flowering, and such

such that admit of it, may be divided, planting them at once in the places allotted them, where they will abide for years, and flower annually.

BUXUS, the Box-tree.

The plants of this genus are hardy evergreen shrubs, well calculated for ornamental purposes in shrubbery works, &c. of which there are but two species, one of them a large shrub, that admits of several beautiful varieties proper for evergreen plantations; the other is also a pretty evergreen of very dwarfish growth, but its chiefest merit is, for forming edgings to flower-beds and borders, for which purpose it is superior to all other plants.

The wood of the large sort is also of singular value for innumerable different sorts of curious utensils.

Class and order, *Monoecia Tetrandia*.

Characters.] CALIX, male and female flowers; the males have a three, and the females a four concave-leaved cup. COROLLA, in the males two, and the females three small concave petals. STAMINA, the males have four filaments, and double antheræ. PISTILLUM, the females have a roundish trigonous germen, three short styles, and hispid stigmas. PERICARPIUM, a roundish trilobular capsule, each cell having two oblong seeds.

The species are,

¹*Buxus Arborescens*.

The Tree-Box.] *Buxus* with a tree-like stem, dividing into numerous branches, forming a regular head, growing twelve or fifteen feet high, and very closely adorned with small stiff shining leaves.

Varieties of this.] Tree-Box with oval leaves, or Broad-leaved Tree-Box—Tree-Box with narrow leaves, or Narrow-leaved Tree-Box—Silver-striped-leaved Tree-Box—Silver-edged-leaved Tree-Box—Gold-striped Tree-Box—Gold-edged Tree-Box—Gold-tipped Tree-Box—Curled-leaved Striped Tree-Box.

²*Buxus Suffruticosa*.

Dwarf Shrubby Box.] *Buxus* with many small, short, very branchy stems, immediately from the root, rising a foot and half high, closely adorned from the very bottom with small, round, stiff leaves.

Varieties.] Dwarf Shrubby Green Box—Dwarf Shrubby Striped Box.

The flowers of all these plants are very inconsiderable, so that the beauty of the shrubs consists in their numerous, shining, evergreen leaves.

All the sorts are so hardy, that they prosper in any exposure and soil, and no weather injures them.

The first species, *Buxus Arborescens*, and its varieties, being of beautiful growth, are elegant furniture for the shrubbery plantations, for having numerous branches, very closely garnished with their small shining leaves, effect a very striking and agreeable contrast at all seasons, in assemblage with the larger-leaved evergreens.

This shrub is also sometimes used in forming low evergreen hedges for ornament, and is likewise sometimes planted as single objects, trained into pyramids, globes, &c.

This sort merits culture also for its wood, which, being very hard, is of singular use to the mathematical-instrument-makers, engravers, and turners, for making innumerable small utensils.

The wood is so compact and heavy, that it will sink in water.

If therefore any one would cultivate this tree for its wood, may plant it on almost any dry poor soil, even on the declivities of chalky or gravelly barren hills, where they will grow freely, as is evident by the vast numbers that adorn Box-hill in Surry, about twenty miles from London, which bring a considerable income to the owner; and what is remarkable, the wood is sold by weight, at so much per pound, which renders it still more valuable to the cultivator.

The second species, Dwarf Shrubby Box, is a valuable little plant, for its usefulness in forming edgings to beds and borders, for which use there is no plant so proper, it fixes its roots so firmly in the ground, and its branches coming out so thick and close to the very surface, that it answers effectually the purpose of a beautiful edging, and of securing the earth of the beds or borders from being forced out, either by heavy rains, or doing the necessary work; so that, as an edging, it is both useful and ornamental.

It may also be trained as a dwarf shrub, permitting it to take its natural growth, when it will make proper furniture for the fronts of small clumps.

This sort is also by the gardeners about London trained in different figures, as globes, pyramids, and the like, for market, which, as it bears the smoke, is proper to plant in pots, to adorn court-yards and balconies.

Propagation of all the Sorts.

The Tree-Box and varieties may be raised abundantly by seeds, layers, and cuttings, though

though the two latter are the methods by which they are most commonly propagated, and indeed is the only method of propagation for the variegated sorts, so as to continue the different kinds with certainty.

If it is however intended to raise the common green sort by seed, sow it in autumn soon after they ripen, in a border of light earth half an inch deep, and the plants will come up in spring, and in two years will be fit to plant out in the nursery-lines.

To encrease them by layers, it may be done any time in the year; but from Michaelmas to March is the most eligible season.

Cuttings of all these tree sorts may be planted in autumn, or even any time in winter or spring, but the sooner the better: chuse shoots of one or two year's wood, about eight, ten, or twelve inches long; plant them in a shady border half way in the earth, and six inches distance, and give water in dry weather.

The Dwarf Box propagates very plentifully by numerous off-sets or suckers from the roots, which may be parted any time from September to April, or even later, upon occasion; observing, those of them you intend to train as shrubs, are to be planted singly in rows in the nursery a foot asunder; but when intended for edgings, they are to be planted close to one another, in the following manner.

Of planting the Dwarf Sort for Edgings.

As before noticed, the Dwarf Box is the best plant for edgings, and its propagation is effected abundantly by dividing the plants into as many parts as are furnished with fibres; also the slips of the branches, having no roots, will grow, but as the plants encrease greatly from the bottom, furnished with plenty of fibres, and are easily parted, it is most adviseable for edgings, to use entirely those slips that are provided with roots.

For the purpose of edgings, such plants as are short and bushy are to be preferred, rejecting such as have long, naked, sticky stems and branches, and preference is to be given to those whose roots are short and very fibrous.

The plants are cultivated for sale, purposely for edgings, in many places, particularly in the nurseries and other gardens about London, which being planted in close rows in the manner of edgings, is commonly sold by measurement, generally from three-pence to six-

pence per yard, running measure, and one yard of good close Box will, when parted, plant three or four.

In slipping or parting the Box for edgings, it is not proper to divide it into very small slips, and, if possible, let each slip be furnished with fibres; for although the naked or rootless slips will grow, they are improper to be planted with the rooted plants, because many may fail, and occasion gaps in the edging. The plants when slipped should be trimmed at root and top, cutting off or shortening long sticky roots, and only trim the straggling tops even; but by no means cut them too close to appear stumpy.

The manner of planting the edging is this.

To plant a close regular Box-edging, the edge of the bed or border which is to be planted must be made up full and even by line, then a slight trench must be cut about six inches deep, in which to plant the Box almost to the top, observe the following directions.

In the first place, proceed to stake out the intended width of your border, walk, &c. and place for the edging; then, if not done before, dig the edge along full and regular, and directly tread the top evenly all the way, to settle the earth equally, that it may not sink in hollows hereafter; then, having previously marked on the stakes the proper height and level for the edging, stretch a line, if for straight work, along the edge, agreeable to the said mark of level, and with a spade make up the ground even to the line, finishing it level and smooth about a spade's-breadth all the way along the top; this done, strain the line tight, and proceed to cut out a slight neat trench for the reception of the edging: the trench must be cut on the walk-side of the line, about six inches deep, cutting the side next the line nearly perpendicular, and as even as possible, turning the earth thereof towards the walk or alley, and it is then ready for the plants.

The Box being trimmed, as before directed, proceed to planting, placing the plants close against the upright side of the trench, and so close together, as at once to form a close and regular edging, with the tops all of an equal height even with the line. As you proceed in planting, draw with the hand a little earth up to the plants, just to fix them in due position till the line or row is finished, then with the spade trim in the remainder of the earth

earth almost even with the tops of the edging, and press it evenly thereto with the foot, to fix the plants as they are to remain, and the work is finished.

When the edging is thus planted, observe, if there are any irregular parts, projecting either on the sides or top, to go over it lightly with the garden-shears, and trim off any such irregularities.

If these edgings are planted late in the spring, or early in autumn, while the dry hot weather continues, it will be necessary to give occasional waterings, but more particularly those planted late in spring.

The planting of Box-edgings may seem a tedious work to those of little practice; but an expert hand will plant many yards in a day. The jobbing-gardeners about London are extremely clever at this work, they having great practice; for those kind of edgings still prevail greatly in the numerous pleasure or flower-gardens in the environs of that city. I have known some of these gardeners for a wager plant sixty yards in an hour, previously, however, preparing the trench, and trimming the box ready for planting.

As to the general culture of these Box-edgings, it consists principally in clipping or shearing them with garden-shears once a year at least, to continue them in regular order, and within due bounds, in respect to height

and breadth, for they should not be suffered to grow above three or four inches high, nor more than about two broad, for if more than that, they assume a clumsy appearance; besides, when permitted to grow high and thick, they afford harbour for slugs, snails, and other destructive vermin.

The time of year to clip or shear these edgings is June; this is to be understood of those that are cut once a year; but to have them extremely neat, they should be clipped twice in the summer, i. e. May, and the beginning or middle of August.

It is advisable to clip them in moist weather, as they then cut freer, and the beauty of the edging is better preserved, than when shorn in a dry and hot time, which is apt to occasion the leaves to turn brown, and have a rusty unsightly appearance for a long time. The same also happens when cut early in spring while frosty nights prevail.

When any of these edgings are grown very broad and clumsy, they should be taken up, slipped or parted, and replanted in a compact neat edging, as above directed. The same should likewise be practised to such edgings as have large gaps in different parts, and such also that are irregular by having high and low places, and where the plants have become naked and stubby.

C.

CACALIA, Foreign Colt's-foot.

This genus furnishes some hardy, herbaceous, tall, flowery perennials of the common ground, and some of shrubby growth for the green-house, garnished with simple leaves, and compound flowers in umbels at the ends of the stalks and branches.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] **CALIX**, compound flowers, having many florets included in an oblong, scaly, general cup. **COROLLA**, several tubulous funnel-shaped florets five-parted at top. **STAMINA**, five small filaments, and cylindric antheræ. **PISTILLUM**, an oblong germen, slender style, and two oblong revolute stigmas. **PERICARPIUM** none, a naked seed in each floret, crowned with down.

The species that merit culture are as follow: the three first species are hardy herbaceous perennials.

¹**CACALIA Alpina.**

Alpine Purple Cacalia.] Cacalia with fleshy spreading roots, sending up many kidney-shaped, thickish, indented leaves, on single foot-stalks, and amongst them the flower-stalk a foot and half high, branching upward, and all the branches terminated by umbels of purplish flowers, three in each cup.

Varieties.] Alpine Purple Cacalia with hoary leaves—with hairy thick leaves—smooth green leaves.

²**CACALIA Suaveolens.**

Sweet-scented Canada Cacalia.] Cacalia with strong very-spreading roots; strong, erect, annual stalks six or seven feet high, garnished with

with triangular, spear-shaped, indented leaves, placed alternate, and white flowers terminating all the stalks in umbels.

³*CACALIA Atriplexifolia.*

Atriplex-leaved Virginia Cacalia.] *Cacalia* with a thick root, having many tubers, sending up strong annual stalks four or five feet high, adorned with roundish, heart-shaped, sinuated, alternate leaves, and yellowish flowers crown the stalks in umbels, having five florets in each cup.

The above three species flower annually in June, July, and August, succeeded by plenty of seeds in October, when their stalks die to the ground, and new ones rise in spring.

The four following are shrubby succulent exotics of the green-house.

⁴*CACALIA Ficoides.*

Shrubby Fleshy-leaved African Cacalia.] *Cacalia* with shrubby, strong, succulent stems and branches, growing seven feet high; fleshy, taper, lance-shaped, pointed, compressed, powdered leaves; and white flowers in small umbels at the ends of the branches, in autumn, winter, or spring.

⁵*CACALIA Kleinia.*

KLEINIA, India Cacalia, or Cabbage-tree.] *Cacalia* with a shrubby, thick, succulent stalk and branches, composed of many swelling divisions or joints; long, narrow, spear-shaped leaves, their foot-stalks leaving scars; and carnation-coloured flowers in large clusters at the ends of the branches, from August to October.

⁶*CACALIA Anteuphorbium.*

Anteuphorbium, or Shrubby Ethiopian Cacalia.] *Cacalia* with many shrubby, slender, succulent stalks, branching irregularly; oval-oblong, flat, succulent, alternate leaves, having three lines at the base of the foot-stalk.

⁷*CACALIA Papillaria.*

Shrubby Papillary Cacalia.] *Cacalia* with a shrubby, large, succulent stalk, branching irregularly; and narrow succulent leaves, their foot-stalks remaining on the branches like thorns.

The three first species and varieties are very hardy herbaceous perennials of the flowery tribe, which although not of any striking beauty, are proper furniture for large pleasure-grounds, to encrease the variety in spacious borders, or in the clumps between deciduous shrubs, or the border of shady walks, &c.

Their propagation is by dividing their roots any time in autumn, winter, or spring.

They may also be raised abundantly by

seeds, either sown, or permitted to scatter which, by means of their downy pappus, are often waisted to a considerable distance, and where they fall come up freely.

The four shrubby succulent sorts, requiring a green-house here all winter, must always remain in pots of light sandy earth, giving moderate waterings in summer, but as little as possible in winter, as being of a very succulent nature.

These plants being singular in their growth, merit a place in every curious collection.

Their propagation is easily effected by cuttings of their branches, any time from March to July. Let the cuttings be five or six inches long, permitting them to lie a fortnight to heal the cut part; then plant them in pots of light mould, which you may plunge in a moderate hot-bed; though those planted in summer generally take root freely without such assistance.

CACTUS, Melo-Cactus, Melon-Thistle;

Includes also the *Cereus*, or Torch-Thistle, and the *Opuntia*, or Indian Fig.

This genus furnishes a curious collection of succulent exotics, of singularly strange and different growths, inhabitants of the hot parts of America, and retained here for curiosity in our stoves and green-houses.

Class and order, *Icosandria Monogynia.*

Characters.] *CALIX*, a monophyllous, tubular-concave, deciduous cup. *COROLLA*, many broad obtuse petals, the exterior ones short, the inner ones largest and connivent. *STAMINA*, numerous filaments inserted in the calix, and erect antheræ. *PISTILLUM*, a germen below the receptacle, cylindric style, and headed multifid stigma. *PERICARPIUM*, an oblong baccaceous fruit of one cell, having numerous seeds.

As the *Melo-Cactus*, or Melon-Thistle, assume very different structures and appearances from the *Cereus*, or Torch-Thistle, and the *Opuntia*, or Indian Fig, many still consider them as three different genera; but their characters being the same, Linnæus ranges them all in the genus *Cactus*, under which we shall also place them, though, for distinction sake, in three different classes, i. e. the *Melo-Cactus*, or Melon-Thistle; the *Cactus-Cereus*, or Torch-Thistle; the *Cactus-Opuntia*, or Indian-Fig.

First Class, the Melo-Cactus, or Melon-Thistle.

The species of *Cactus* called Melon-Thistle, are plants of very singular structure, being shaped like a great melon, having neither

visible

visible stem, branches, nor leaves, but appear like a large roundish fleshy mass or lump, sitting close to the earth, growing a foot or more high, some deeply ribbed longitudinally, and all of them closely armed with robust thorns, and some are crowned with a large tuft of downy matter, intermixed with sharp spines.

There are but two real species of this sort, which are,

¹*CACTUS Melo-Cactus.*

Great Melon-Thistle.] Cactus with a roundish body a foot or more high, having fourteen or fifteen longitudinal angles or ribs, each beset with nine or ten very thorny tubercles, and at top a large downy prickly crown, from which issue the flowers and fruit.

Varieties.] Great Melon-Thistle with straight angles—with angles spirally twisted—with contorted angles—with broad recurved spines.

²*CACTUS Mammillaris.*

Mammillary, or Smaller Melon-Thistle.] Cactus with a roundish oblong body near a foot high, closely covered with smooth tubercles, each armed with brown thorns disposed in a radius, and between the tubercles whitish flowers in August, succeeded by oblong crimson fruit ripening in winter.

Variety.] Small Melon-Thistle with white spines.

All the sorts are perennial both in root and top, and are of many years duration.

These very singular plants are natives of America, growing in the crevices of rocks, having scarce any earth for their support, where the first sort grows near a yard high, and half a one or more in diameter.

In this country they are preserved as plants of curiosity, and require the constant accommodation of our best stoves, and must be planted in pots of light sandy earth, placing them upon the top of the flues or shelves in winter, and in the bark-bed in summer, giving but very moderate watering in the hottest weather, and none at all in winter, they being of themselves very succulent and replete with moisture.

Their Propagation.

The propagation of these plants in England is by seed, in pots of light sandy earth, plunged in the bark-bed, where they will soon come up, which, after having advanced a little in growth, should be pricked in sepa-

rate very small pots, plunging them also in the bark-bed, and they will make great progress, though it will be some years before they acquire any considerable size.

Young plants sometimes issue from the sides of the old ones; these may be taken off and planted, managing them as above.

But some, to have large plants as soon as possible, procure them from the West-Indies in tubs of dry rubbishy compost, being careful during the voyage to guard them from cold and every sort of moisture, and as soon as they arrive, plant them in pots, and plunge them in the bark-bed till rooted.

Second Class.

CACTUS CEREUS, the *Cereus*, or Torch-Thistle, and Creeping Cereus.

This class consists also of succulent perennial exotics of America, of singular structure and port, and retained here for variety in our stoves.

Class, order, and characters, the same as the *Cactus Melo Cactus*.

The Cactus of this class are vastly different in structure and general habit from those of the preceding; those of this class advance with long, angulated, naked, succulent stalks; some erected singly like a column to thirty or forty feet in height, having neither branches nor leaves; others are of creeping growth, with long, climbing, rooting stalks, branching and mounting themselves upon support to a great distance, and some trail upon the ground; all of which are for most part leafless, but most of them produce most elegant multipetalous flowers, which, in some of the climbing kinds, are of wonderful size and beauty, spreading like an umbrella a foot or more in diameter; and what is more remarkable, they appear only on nights, and which being so extremely fugaceous, that, opening fully about ten or eleven o'clock, they continue expanded three or four hours, then begin to shut and fade, and by six or seven in the morning are quite closed, hang drooping, and in a manner withered and decayed, never opening any more, though they are often succeeded by fresh ones on the same plant the following night; and those of all the sorts, in their native soil, are succeeded by a large, roundish, eatable fruit, but rarely ripen in perfection here.

They are preserved here in many of our hot-houses as curiosities, and, as such, highly demand the attention of the curious.

The

The species of this class are,

¹*CACTUS-CEREUS Hexagonus.*

Great Upright Sexangular Torch-Thistle.] Cactus with an upright, sexangular, strong, fleshy, branchless stalk or column, growing thirty or forty feet high, armed with spines in radiated clusters; and from the angles large white flowers in prickly cups on thick fleshy foot-stalks, appearing in July, but rarely any fruit in England.

²*CACTUS-CEREUS Tetragonus.*

Upright Smaller Quadrangular Torch-Thistle.] Cactus with an upright, four-angled, fleshy stalk, five or six feet high, sending out many erect side-shoots, the angles compressed and armed with clusters of spines.

³*CACTUS-CEREUS Pentagonus.*

Upright Pentangular Torch-Thistle.] Cactus with an upright, five-angled, jointed column, twelve or fifteen feet high, having the joints far asunder, and the angles armed with spines.

⁴*CACTUS-CEREUS Heptagonus.*

Upright Septangular Torch Thistle.] Cactus with an upright, oblong, seven-angled, fleshy stalk, having the angles armed with spines.

⁵*CACTUS-CEREUS Repandus.*

Upright Repand-octangular Torch-Thistle.] Cactus with an upright, somewhat slender, eight or nine-angled stalk, the angles compressed and undated, armed with clusters of spines at a distance, and greenish flowers in June, succeeded by large yellowish pear shaped fruit, sometimes ripening in England.

⁶*CACTUS-CEREUS Peruviana.*

Upright Peruvian Octangular Torch-Thistle.] Cactus with an upright, eight or nine angled, fleshy stalk, twenty or thirty feet high, the angles slight, obtuse, and spinous, flowering in July, succeeded by a reddish, smooth palatable fruit.

⁷*CACTUS-CEREUS Lanuginosus.*

Upright Novem-angular Downy Torch-Thistle.] Cactus with an upright, slightly nine-angled, thick, fleshy, downy stalk, many feet high, armed with spines shorter than the down.

⁸*CACTUS CEREUS Royeni.*

Royen's Upright Decem-angular Torch-Thistle.] Cactus with an upright, articulated, ten-angled, fleshy stalk, the articuli or joints oval, and the spines and down of equal length.

The following are the creeping Torch-Thistle.

⁹*CACTUS-CEREUS Grandiflorus.*

Climbing Pentangular Grand-flowered Torch-Thistle.] Cactus with climbing, five-angled, jointed, slender, branchy stalks, rooting at

the joints, and extend considerably, producing grand, snowy white flowers, having large bright-yellow cups, expanding almost a foot diameter, of splendid beauty and most fragrant odour, opening in an evening, and by next morning are closed, hang drooping, and decay.

¹⁰*CACTUS-CEREUS Triangularis.*

Climbing Triangular Torch-Thistle.] Cactus with climbing, three-angled, jointed, slender, branchy, prickly stalks, rooting at the joints, and extend to a great distance, producing large, beautiful, nocturnal flowers, decaying next morning.

¹¹*CACTUS-CEREUS Flagelliformis.*

Trailing Decem-angular Flagelliform Torch-Thistle.] Cactus with trailing, finely ten-angled or fluted, long, slender, prickly stalks, not jointed, rooting, nor climbing, but, if not supported, extend along the ground, producing many elegant bright-purple flowers annually in May of two or three days duration.

In all the sorts, the flowers are composed of many broad petals, and each flowers stand on a short foot-stalk.

All these species of *Cactus-Cereus*, or Torch-Thistle, are succulent perennial exotics of the stove, perennial both in root and top, continuing their growth many years, always assuming a green colour.

They are all natives of the warm parts of America, and in this country require a stove; must therefore be always kept in pots of light, dry, sandy earth, and continued constantly in that department; for, although they will live in the open air in hot weather in summer, they are too apt to imbibe moisture, and being themselves very humid, may occasion them to rot, nor will they so certainly flower as when retained in the stove.

Be sure always to pot them in light dry earth, and give them but very moderate waterings in summer, and very little, or none at all, in winter.

The upright kinds arrive to a great height in America; and in this country, in our stoves, they often obtain ten or fifteen feet stature, and were there room, they would apparently grow several feet higher; but when they reach the top, we are obliged to shorten them, in which case they issue forth side-shoots, proceeding in an upright direction like the main stem, and, if taken off and planted, they readily emit roots, and become proper plants.

The

The creeping kinds will also extend themselves considerably, provided they have support, so should be placed near the walls of the stove, and their branches trained thereto, which, of the *Grandiflorus* and *Triangularis* kinds, will root in the plaister-work as they ascend.

Most of the species, both the upright and creeping kinds, produce flowers in this country, though not all of them annually, and some not in two, three, or more years; for they have no certain period of flowering here, and the flowers are very rarely succeeded by fruit.

No flowers however are, at any rate, to be expected till the plants have obtained several years growth, to acquire due strength.

The first and twelfth of these species are the hardiest of all, and may be preserved in a good green-house, giving no water in winter, and will endure the open air from June till September, but rarely flower well unless indulged with a stove.

Propagation of all the Sorts.

They are all propagated by cuttings of their stems and branches, in pots plunged in a bark-bed or other hot-bed, in May, June, or July.

When intended to propagate any of the upright sorts, supposing the plant to have only one stem and no side-shoots, there is no other method of encreasing it than by cutting off the top to what length you please, which cutting, after lying in a dry place about a fortnight to heal the succulent wound, is to be planted in a pot of light compost, and plunged in the bark-bed, &c. and it will readily strike root and grow. The remaining part of the old plant, from which the above cutting was taken, will soon put forth lateral shoots, which, when from three to six or eight inches long, may be taken off, and planted singly in pots, as above directed, and the old plant continues to furnish a supply of fresh shoots annually.

The creeping kinds having several stalks and branches, may be propagated plentifully, taking off cuttings of them from about three to five or six inches long, treating them as above.

Cuttings of all these plants will keep two or three months out of the earth, in a dry place, if necessary.

Third Class.

¹CACTUS-OPUNTIA, the *Opuntia*, or Indian Fig, or Prickly Pear.

This class of Cactus consists also of curious succulent exotics, mostly of American growth, and require the aid of green-houses and stoves in this country.

Class, order, and character, the same as the CACTUS *Melo-Cactus*.

The plants of this class are composed of a multitude of thick, fleshy, compressed, prickly leafless branches, growing out of one another in many oval and oblong articuli or joints, some compressed or flat, others ventricose or bellied; some loosely disposed and spread near the ground, and some grow erect; all the sorts producing multipetalous concave flowers from the surface and upper edge of all the articulations, succeeded by large, oblong, succulent, fig-shaped, prickly fruit, which in some of the sorts sometimes ripen in our gardens.

The plants in general are perennial in root, stem, and branches, have scarcely ever any leaves, but their succulent branches always assume a green colour.

The species of this class are,

¹CACTUS-OPUNTIA *Opuntia*.

Common Opuntia, or Indian Fig.] Cactus with low, spreading, loose branches, composed of many oval compressed joints, having knots on the surface, armed with slender bristly spines, and yellow flowers at the upper parts of the articuli, succeeded by oblong, prickly, purple fruit, sometimes ripening in England.

²CACTUS-OPUNTIA *Ficus Indica*.

Greater Common Indian Fig.] Cactus with many somewhat erect branches, composed of many oblong, oval, compressed joints, armed with long bristly spines in radiated clusters, and yellow flowers from the edges of the articuli, succeeded by large, purple, prickly fruit.

³CACTUS-OPUNTIA *Tuna*.

Tuna Major, or Great Indian Fig.] Cactus with erect strong branches several feet high, composed of many large oval articulations, armed with numerous clusters of long awl-shaped spines, and yellowish flowers.

⁴CACTUS-OPUNTIA *Cochinillifer*.

The Cochineal Great Indian Fig] Cactus with erect, strong, very green, articulate branches, rising eight or ten feet high, composed of many oval, oblong, compressed, smooth articuli, almost without spines, and small purplish flowers from the surface, succeeded by a large succulent fruit, having a blood-red pulp, on which feeds the cochineal insect, so valuable in dying scarlet colour.

Upon

Upon this species, which is a native of Mexico and the West-India islands, is found the insect or bug called cochineal, which is used by the dyers as their principal basis for scarlet colour. It is a six-legged viviparous insect, produced from an egg in its perfect form, not undergoing any transformation: it has no wings, nor, indeed, has it use for any, the greatest part of its life being spent on the vegetable whereon it feeds.

⁵CACTUS-OPUNTIA *Curassavicus*.

Low Ventricose Opuntia of Curassoa, or Pin-pillow.] Cactus with low, spreading, jointed branches, composed of many cylindric, very swelling, ventricose or bellied articulations, closely set with white spines; by the Americans is called Pin-pillow.

⁶CACTUS-OPUNTIA *Spinosissima*.

Most Spinous Opuntia, or Robinson Crusoe's Coat.] Cactus with jointed branches, composed of very long, narrow, compressed joints, very closely armed with clusters of long, slender, brownish spines, crossing each other every way; hence sometimes called Robinson Crusoe's Coat.

⁷CACTUS-OPUNTIA *Periskia*.

Periska, or American Gooseberry.] Cactus with a woody, taper, prickly stem; slender, spreading, succulent branches, armed with long whitish spines; lanceolate-oval, thick, succulent leaves, whitish flowers, and a gooseberry-shaped fruit.

⁸CACTUS-OPUNTIA *Phyllanthus*.

Sword-blade Notched Opuntia.] Cactus with many long, articulate, smooth, spineless branches, composed of long, sword-shaped, very flat, thin joints, having repand indented edges, and from the indentures many pale yellow flowers.

These are all the principal species of the Cactus - Opuntia cultivated in the British gardens.

The first of these species, *Common Opuntia*, is the hardest of all the sorts, as it may be preserved in England by the shelter of a green-house or garden-frame in winter, and it will sometimes live all the year in the full ground under a warm wall; it is however proper to keep some in pots, to have shelter from frost.

All the other sorts require a stove most part of the year; for, although they will live in the full air two or three months in summer, and in a good green-house in winter, they, for want of a due temperature of warmth, are apt to assume a yellowish hue, and gra-

dually dwindle off; but when kept mostly in the stove, they always retain their respective natural green colour, and are more prolific in their flower and fruit: they, however, at any rate, must never be fully exposed, but only two or three months in the heat of summer, and but very little in wet seasons.

All the sorts should always be continued in pots of light sandy soil, or dry rubbishy compost, giving frequent light waterings in summer, and also now and then lightly in winter, especially those in the stove.

Their Propagation.

They are propagated very easily by cuttings or joints of their branches, which may be taken off and planted in pots of light sandy compost any time from the beginning of May to the end of July, but the sooner the better.

The cuttings are to be cut off in joints, which, previous to planting, must, like other succulents, be laid in a dry place ten or fifteen days, to heal over the cut part; then plant them in pots as above, and if the hot-house kinds are then plunged in the bark-bed, or other hot-bed, it will greatly promote their rooting; but the green-house sort, Common Opuntia, will readily strike root without that aid, though they may be greatly forwarded by such assistance, giving all the sorts now and then moderate waterings, just to moisten the earth a little.

CALENDULA, the Marigold.

This genus of plants consists of herbaceous bushy annuals, one low perennial, and one shrubby plant: the former comprises hardy culinary herbs and flowery plants, and the two latter ornamental plants for the green-house, all of which have simple leaves, and compound radiated flowers.

Class and order, *Syngenesia Polygamia Necessaria*.

Characters.] CALIX, a compound radiated flower, having a simple multipart general cup. COROLLA is compound, and consists of numerous tubular hermaphrodite florets in the disk, and many long flat females compose the rays. STAMINA, the hermaphrodites five short filaments and cylindric antheræ. PISTILLUM, the hermaphrodites an oblong germen, slender style, and blunt bifid stigma; the females a trigonous germen, slender style, and reflexed stigma. PERICARPium none. SEMEN, a single, oblong, incurved seed, in the female florets.

The species of note are as follow: the three
first

first species and varieties are hardy annuals of the full ground.

¹CALENDULA *Officinalis*.

Officinal, or Common Garden Marigold.] Calendula with a short stalk, dividing low into many bushy branches a foot or two high, closely garnished with oblong oval leaves, and numerous radiated golden flowers at the ends of the branches, succeeded by boat-shaped, incurved, rough seeds.

Varieties of this are] Common Marigold with single yellow flowers—with double yellow flowers.—Giant Common Marigold with very double flowers—with single lemon-coloured flowers—double lemon-coloured flowers—with single and double gold coloured flowers—with party-coloured flowers—with reflexed flowers—with proliferous or childing flowers, having many small flowers issuing from the calix of the main one all around; of which there are, the Small Proliferous Marigold—Great Proliferous Marigold.

All these varieties are hardy annuals, rising from seed in the full ground in spring, commonly flower in May or June, continuing a plentiful succession until November, succeeded by abundance of seed, which, if gathered with care from the best of each respective sort, may all be continued in distinct perfection; this should be particularly observed in the Giant and other fine double and Proliferous kinds.

²CALENDULA *Pluvialis*.

Cape Leafy-stalked Violet and White Calendula.] Calendula with slender, very leafy, declining stalks, six or eight inches long; spear shaped, sinuated-indent leaves; and flowers from the ends of the branches, having the rays violet-coloured without, and white within, and purple bottoms.

³CALENDULA *Nudicaulis*.

Naked-stalked Violet and White Ethiopian Low Calendula.

The two following are green-house perennials.

⁴CALENDULA *Graminifolia*.

Grass-leaved Low Perennial Cape Calendula.] Calendula with several tufted heads near the root, covered with long, narrow, grassy leaves, and amongst them naked stalks eight or nine inches long, each crowned by one large radiated flower, having the rays purple without, white within, and purple bottoms, appearing from April till autumn.

⁵CALENDULA *Fruticosa*.

Shrubby Cape Calendula.] Calendula with

shrubby slender stalks and branches, growing six or seven feet high, garnished with oval leaves, and the branches terminated by radiated flowers, having the radius purple without, white within, and purple middles, appearing several months in summer.

The flowers of all the sorts being compound and radiated, they, in their single state display a naked disc, or middle, composed of numerous, very small, tubular florets; one or two series of flat spreading ones form the radius, ray, or border; but in the full double flowers, the plenitude consists of numerous flat florets, continued in many series from the circumference to the very centre, forming a large full flower.

The first sort, *Calendula Officinalis*, in its common single-flowered state, is regarded only as a pot-herb, and its flowers are the only parts used; but some of the full double varieties and proliferous kinds demand attention also as ornamental plants for the beauty of their flowers, which will effect an agreeable diversity in the common compartments of the pleasure ground, in assemblage with other hardy annuals.

Likewise the second and third sorts, being hardy annuals, will flower abundantly, and form a good variety in the open borders in June, July, and August.

The fourth and fifth sorts, Grass-leaved and Shrubby Calendula, producing many flowers in long succession, are also worthy of a place in our gardens; but being impatient of frost, must be kept in pots, to have shelter of a green-house or frame in winter.

Propagation of all the Sorts.

All the annual sorts are propagated by sowing the seeds in beds or borders in March or April, either in the places where they are to remain, or for transplanting.

When intended to cultivate the first sort for culinary uses, may either sow the seeds where the plants are to remain, by broadcast on the surface, and rake them in, or sow them in small shallow drills a foot asunder, covering them half an inch deep, and when the plants in either method have leaves an inch broad, hoe them out to twelve inches distance; or they may be sown thick for transplantation, and when the plants have four or five leaves, plant them out in rows the above distance.

Their flowers being the useful parts, they will be fit for use in constant succession from time

time to time in dry weather, and, after drying them in the shade, should be put up in paper bags for use.

To propagate the annual kinds in general as flowering plants, sow them either in patches in the borders, &c. where they are to remain, sowing four or five seeds in each patch half an inch deep, but leave only one of the best of the plants in a place; or the plants may be raised in a bed or border, and when they have four or five leaves, transplant them in the order just directed.

They will flower and ripen seeds abundantly from June to the end of October.

The fourth sort is propagated by slipping the heads any time from March till September, planting them in pots, which, if plunged in a hot-bed, or in the common earth, and close covered with a hand-glass, and occasionally shaded and watered, they will readily grow, hardening them gradually to the air.

The shrubby sort is propagated by cuttings of its branches, in pots of light earth, in April, May, or June, plunging them in a moderate hot bed, or, in default thereof, plunge them to the rims in the common ground, giving shade and water.

CALIX, the empalement or flower-cup, which is the green outer part of a flower, that immediately incloses and supports the bottom of the corolla or petals. See **COROLLA**.

According to modern botanists there are seven species of Calix, viz.

¹*Perianthium*, which is considerably the most common species, and is that sort of Calix which closely surrounds the flower. When we speak therefore of the proportion, figure, or singularity of the Calix, we would be understood to mean that species of Calix called *Perianthium*. See **PERIANTHIUM**. The other species, which differ remarkably both in appearance and structure from this, are always denominated by their own proper names to avoid confusion, and which are termed

²*Involucrum* is a Calix at a distance from the flower, and belong principally to the umbelliferous plants. See **INVOLUCRUM**.

³*Amentum*, or Katkin, is composed of a multitude of scales, fastened to an axis or thread. See **AMENTUM**.

⁴*Spatha*, a sheath, which bursts lengthways, and protrudes one or more flowers, as in the Narcissus, &c. See **SPATHA**.

⁵*Gluma*, the husky Calix of the grasses. See **GLUMA**.

⁶*Calyptra*, the Calix of the mosses, is membranous, very thin, and shaped like an

extinguisher, and is placed over the antheræ. See **CALYPTRA**.

⁷*Volva*, the Calix of the *fungi*, or mushroom tribe is membranous, and torn on the sides. See **VOLVA**.

The use of the Calix is to inclose, secure, and support the other parts of the flower; to be their security before its opening, by intercepting all extremities of weather, and afterwards to be their support, by containing all the parts in their due and most graceful posture. Hence we have the reason why the Calix is frequently various, and sometimes wanting. Some flowers have none, as tulips, and many other liliaceous plants; because having a fat, firm leaf or petal, and each leaf likewise standing on a broad and firm basis, they are thus sufficient in themselves. Carnations, on the contrary, have not only a Calix, but that for greater support, it is long, and of one piece; for otherwise, the foot of the petals being very long and slender, most of them would break out of compass; in the same flower the top of the Calix is indented into five parts, that the indentments, by lapping over the petals before their expansion, protects them; and afterwards the same parts, by spreading regularly under the Corolla when expanded, affords it support. The Calix or cup in most plants is single; in some genera of the mallow tribe, as *alcea*, the holyhock, and *Althea*, marsh-mallow, it is double, or of two series.

With respect to the number of leaves or pieces of which the Calix is composed, is either of one leaf, *monophyllum*; or of two, *di-phyllum*; of three, *triphyllum*; or four, *tetraphyllum*; of five *pentaphyllum*, &c. or many leaves, *polyphyllum*; and when one is leaf divided into two, three, four, five, or more parts, it is termed *monophyllum-bifidum*, *trifidum*, *tetrasidum*, *quinquesidum*, &c. which leaves and divisions are either equal, as in most plants; or unequal, as in rock-rose, &c. in which, two of the five leaves of which the Calix consists, are alternately less than the other three.

With respect to proportion, the Calix is generally shorter than the corolla in most plants, though in some genera it is equal, and in some longer.

With respect to composition, the Calix sometimes consists of a number of leaves laid over each other like tiles or scales, *imbricatum*, as in hawk-weed, &c. sometimes of scales that spread wide and are diffused, or diverge on all sides *squarrosum*, as in the thistle.

C A L

As to duration, the Calix either falls off at the first opening of the flower, *Calix caducum*, as in the poppy. With the flower, *Calix deciduum*, as in the barberry and the cross-shaped flowers; or continues till the maturity of the fruit. *Calix persistens*, as in the lip and masqued flowers, and several others.

Lastly, a Calix is proper to one flower, as in most plants with simple flowers; or common to many, as in scabious and the compound flowers.

CALLA, *Æthiopian Arum*.

Of this genus is one beautiful, herbaceous, flowery perennial of the green-house, adorned with large radical leaves, and a two-foot stalk, crowned by spadiceous yellowish flowers.

Class and order, *Gynandria Polyandria*.

Characters.] **CALIX**, a monophyllous, oval, heart-shaped, coloured, permanent spatha, protruding a digitated, single, erect club or spadix, covered with the fructifications. **COROLLA**, no petals. **STAMINA**, many very short filaments, and small yellow antheræ. **PISTILLUM**, a roundish germen, simple style, and acute stigma. **PERICARPIUM**, each germen becomes a globular, pulpy, unilocular berry, containing a few obtuse seeds.

The species is,

CALLA *Æthiopica*.

Æthiopian Arum, or Sweet Calla.] Calla with a tuberous, thick, fleshy, brown root, crowned by clusters of large heart-shaped, arrow-pointed leaves, on very long foot-stalks; and amongst them upright flower-stalks two feet high, terminated by a single spatha, protruding a yellowish spadix, covered with whitish fructifications of a musky fragrance, succeeded by roundish red berries.

It is furnished with leaves all the year, flowers in May, and the whole plant effects an agreeable singularity.

This species being an exotic of Africa, requires shelter here in winter, so must be continued in pots of light earth, to be moved to a green-house or garden-frame in that season, but should be placed in the full air from May till October.

It propagates exceedingly by off-sets, which may be separated in September, planted singly in small pots, and they will flower the year following.

CALTHA, Marsh Marygold.

One species only belong to this genus, a low, herbaceous, flowery perennial of but six or eight inches stature, producing many showy yellow flowers.

Class and order, *Polyandria Polygynia*.

C A L

Characters.] **CALIX** none. **COROLLA**, five large, spreading, concave petals. **STAMINA**, numerous filaments, and obtuse erect antheræ. **PISTILLUM**, several oblong compressed germina, no styles, but simple stigmas. **PERICARPIUM**, several short acuminate capsules, containing many roundish seeds.

The species is,

CALTHA *Palustris*.

Marsh Marygold.] Caltha with fibrous perennial roots, crowned by many round crenated leaves on short foot-stalks, and amongst them several branching flower stalks six or eight inches high, surmounted by large bright-yellow flowers, in April, May, and June.

Varieties.] Common Single-flowered Marsh Marygold—Double Marsh Marygold.

The single kinds have but five petals, but the doubles are multiplied to the very centre, forming a large, fair, full flower.

This species, in its single state, ornaments our moist meadows contiguous to brooks, rivers, or other waters, in many parts in great abundance, among which the double was found, and which merits a place among our hardy flowering perennials in the embellishment of shady borders, though it will prosper in any situation.

Its propagation is easily and abundantly effected by slipping or parting the roots in autumn, and each slip will flower the following year.

CALLICARPA, *Callicarpa*.

This is a hardy deciduous shrub of four or five feet stature, dividing low into numerous branches, garnished with roundish, acute, somewhat hoary leaves, and numerous small, reddish, monopetalous, four-parted flowers in whirls, having numerous stamina and styles.

It is proper for the shrubbery, and is propagated by seeds, layers, and cuttings.

CALYCANTHUS, Carolinian All-Spice tree.

This genus furnishes a hardy, deciduous, aromatic shrub, for the shrubbery plantations.

Class and order, *Icosandria Polygynia*.

Characters.] **CALIX** is monophyllous, cut into many spear-shaped coloured folioles. **COROLLA** none; the calicinal folioles supply the place of petals. **STAMINA**, many filaments, and oblong fulcated antheræ. **PISTILLUM**, numerous germina, and naked stigmas. **PERICARPIUM** none; the calix thickens to an oval fruit, containing many seeds.

The species is,

CALYCANTHUS *Floridus*.] Calycanthus with a shrubby brown stem, branching four

or five feet high, having an aromatic bark; large oval, pointed leaves, by pairs opposite; and dull-purple starry flowers, placed singly towards the ends of the branches, having the inner petals the longest.

In America it has the appellation of All-spice, from the aromatic spicy odour of its bark.

This shrub should have a warm situation and dry soil, in the fronts of the principal shrubbery compartments. And its propagation is by layers of the young branches, or one year's shoots, which in one year will be rooted fit for transplantation.

CALYCULA, the Calix of a floret in an aggregate flower.

CALYCVLATUS Calix, an augmented Calix, or a flower-cup furnished with a lesser flower cup, or small leaves placed close to the base of the cup, or to the flower.

CALYPTRA, the Calix of the mosses. See CALIX.

CAMPANIFORMES Plantæ, plants that produce Campanulate, or bell-shaped flowers, such as the *campanula* or bell-flower, *trachelium* or throat-wort, *convolvulus*, *lobelia* or cardinal's flowers, *asclepias*, *atropa*, *bryonia*, *tamus*, *apocynum*, *hibiscus*, or *althæa frutex*, &c.

CAMPANULA, Bell-flower.

This genus furnishes a beautiful collection of herbaceous annual, biennial, and perennial flower-plants; the perennials are much the most numerous, and grow from about two to seven feet high, garnished with simple leaves, and numerous monopetalous, very conspicuous, bell-shaped, blue, purple, and white flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a monophyllous, five-parted cup placed on the germen. COROLLA, a single bell-shaped petal, five-parted at top, and in the bottom, a five-parted Nectarium. STAMINA, five short filaments inserted into the top of the valves of the Nectarium, and oblong compressed antheræ. PISTILLUM, an angular germen below the receptacle, slender style, and tripartite stigma. PERICARPIUM, a roundish, angular capsule of three or five cells, and the same number of holes for the dispersion of the seeds.

The species of most note are: the first four are hardy perennials.

¹CAMPANULA *Pyramidalis*.

Pyramidal, or Steeple Bell-flower.] Campanula, with large, tuberous, milky roots, upright, strong, smooth stalks, a yard or more high, garnished with oblong-oval, a little serrated, smooth leaves, decreasing in size

upward, and numerous, large, bell-shaped flowers, forming a pyramid from the middle to the top of the stalk.

Varieties.] Pyramidal blue flowered Campanula—with white flowers—with double flowers.

²CAMPANULA *Persicæfolia*.

Peach-leaved Campanula.] Campanula with very fibrey roots, crowned by numerous oblong leaves; many upright, angular stalks, two feet and a half high, garnished with long, narrow, stiff, close-fitting leaves, and towards the top many large, bell-shaped, expanded flowers in June and July.

Varieties of this are] Peach-leaved, single, blue flowered Campanula—with double blue flowers—with single white flowers—with double white flowers.

³CAMPANULA *Trachelium*.

Great Throat-wort, or Nettle-leaved Campanula.] Campanula with fibrey roots, upright, angular, hairy stalks, two or three feet high, emitting short side-branches, ornamented with oval, oblong, deeply sawed, foot-stalked, hairy leaves; and towards the top, trifid foot-stalks supporting spreading bell-shaped flowers having hairy cups, appearing in June.

Varieties of this are] Great Throat-wort with single blue flowers—double blue flowers—single white flowers—double white flowers—single and double pale purple flowers.

⁴CAMPANULA *Latifolia*.

Great Broad-leaved Campanula, or Giant Throat-wort.] Campanula with thick, fleshy, milky roots, upright, strong, round, taper, unbranching stalks, six or seven feet high, garnished with broad, oval-spear-shaped, serrated, alternate leaves, and the upper part with bell-shaped, deeply cut, spreading flowers growing singly on short foot-stalks.

Varieties.] Great broad-leaved Campanula with single blue flowers—double blue flowers—single and double white flowers—single and double pale-red flowers—with striped flowers.

The following is a hardy biennial:

⁵CAMPANULA *Medium*.

Middle, or Biennial Campanula, commonly called Canterbury Bells.] Campanula with thick fibrey roots, crowned by many oblong, rough, hairy leaves; an upright, robust, furrowed, pyramidally branching stalk, two feet high, garnished with long, narrow, sawed, hairy leaves, placed alternate, and numerous large bell-shaped, ventricose flowers, on long foot-stalks, arising pyramidally almost the whole length of the stalk, appearing in June and July, succeeded by quinquelocular capsules.

Varie-

Varieties.] Canterbury Bell-flower with blue flowers—purple flowers—white flowers—with striped flowers—with double flowers: the two latter of which are rare.

The two following are hardy annuals.

⁶CAMPANULA *Speculum*.

Venus Looking-glass.] Campanula with a very branching, diffused, angular stalk, about a foot high, ornamented with oval, oblong, close-fitting leaves, and all the numerous branches terminated each by one small, bell-shaped, five-parted flower, in long solitary cups, succeeded by prismatic capsules, flowering most part of summer and autumn.

Varieties.] Venus Looking-Glass with bright blue flowers—with white flowers—pale purple flowers.

⁷CAMPANULA *Hybrida*.

Lesser Venus Looking-glass.] Campanula with a low stalk, eight or ten inches high, branching from the bottom, garnished with oblong, crenated, close-fitting leaves, and all the branches terminated by small, bell-shaped, five-parted flowers, in aggregate cups, succeeded by prismatic capsules, flowering in June and July.

The two following are green-house perennials.

⁸CAMPANULA *Canariensis*.

Canary Bell-flower.] Campanula with thick, fleshy, milky, penetrating roots; upright round stalks seven feet high, sending out many side branches, garnished with spear-shaped, indented foot-stalked leaves, placed opposite, and from the joints large, perfectly bell-shaped, flame-coloured, reddish, striped flowers, hanging downward, succeeded by quinquelocular capsules; flowering in September and October, often continuing till spring.

⁹CAMPANULA *Americana*.

American Bell-flower.] Campanula with a thick fleshy root, crowned by a clustered head of oblong, crenated, rigid leaves, an upright branching stalk a foot and a half high, adorned with heart and spear-shaped membranous-bordered leaves, having ciliated foot stalks; and from the axillas many long pedunculi, each terminated by a large, bell-shaped, five-parted, spreading flower, in July and August.

Varieties.] American Bell flower with single white flowers—single blue—double blue.

The flowers of all the species and respective varieties consist of only one large bell-shaped petal, which in different species is more or less five-parted and spreading, and which in most of the sorts is succeeded by plenty of seeds in our gardens.

The first four species are hardy, very beautiful, flowery perennials; they are perennial only in root, which is of many years duration, crowned with numerous leaves, and amongst them rise the flower-stalks annually in spring, flowering chiefly in June, July, and August, succeeded by abundance of seed, and soon after die down to the root; they producing numerous flowers in long succession, renders them choice furniture for the pleasure-ground, and grow freely in the common borders, or other compartments, in any exposure. The first sort, however, being somewhat impatient of wet and very severe frost, should have a dry soil and sheltered situation; and some should also be placed in pots, to be moved to occasional shelter in severe weather; and in summer, when in flower, they may be moved in their pots to adorn any particular part, for they are very flowery and ornamental; and if their stalks are trained to sticks, fan-fashion, they will appear to considerable advantage, and in which order they are often placed to adorn halls and other apartments in summer, placing them in the chimnies, where they will continue a long time ornamental.

The fifth sort (*Campanula Medium*) and varieties are most elegant biennials, and fine furniture for any part of the pleasure-ground; but as being biennials, never flower but once, they rising from seed one year, the next they shoot up stalks, flowers, and perfect seeds, and soon after totally perish; so that a supply must be annually raised from seed.

The two annual sorts are proper furniture to adorn the fronts of borders, on the sides of spacious walks, in patches, among other hardy annuals. See ANNUAL PLANTS.

The two green-house sorts are plants of superior beauty when they flower, particularly the *Campanula Canariensis*. The roots of both are durable, but the leaves and stalks are renewed annually, and flower freely, but rarely afford us seeds in England: they must be kept in pots of light earth, and moved to the shelter of a green-house or garden-frame in winter.

Propagation of all the Sorts.

The first four species and varieties are propagated plentifully by slipping or parting their roots in September, October, or early in spring. They may be also raised abundantly by seed, in a bed or border of common earth in March, sowing it on the surface, and rake it in; and the plants should be pricked out in July,

C A M

July, which in October or November transplant into the borders, where they will flower the following summer. But as there seldom rise any but single flowers from seeds, the double kinds therefore are increased with certainty no other way than by dividing the roots, every off-set or slip of which having fibres will readily grow; but it is not proper to part them too small, unless when intended to have as great an increase as possible, in which case the small slips should be planted in nursery-beds a year to get strength; but the large slips may be planted at once, where they are to remain to flower.

But it is proper to observe of the first sort (*Pyramidal Campanula*), that the roots do not multiply so fast as the others, nor are they of so long duration; it is therefore necessary to raise a supply of them often from seed, and seedling-plants generally flower strongest. Let seeds therefore be sown in autumn, or early in spring, in large pots, boxes, or tubs of light rich compost, covering the seed half an inch deep, and place them in a frame to have occasional shelter of glasses in very cold, wet, or severe frosty weather, but fully expose them in mild days. By this care the plants will appear in April or May, and by September will be of due size to transplant, doing it when their leaves decay, planting them in a high-lying bed or border of light earth, at six inches distance, with their crowns half an inch deep. Here let them remain two years, giving occasional shelter in winter, and weeding and water in summer; then in autumn finally transplant them, some into pots, others close under a warm wall, and some disperse in open dry borders among other perennials.

The fifth sort (*Canterbury-bell*) and varieties, being biennials, can only be raised from seed, sown annually in March, April, or May: sow it in a bed or border of good earth by broad-cast, and rake it in, and the plants will be fit to prick out in June or July, planting them six inches apart, to remain till autumn or spring following; then transplant them, with little balls of earth to their roots, in the places where they are to flower.

The two annual sorts are also raised from seed, sowing it a quarter of an inch deep, in small patches, in different parts of the borders, in the place where they are to flower, permitting several plants to remain in each patch.

The Canary *Campanula* is propagated by off-sets of the roots in July, when the stalks decay; these being succulent milky roots, it

C A N

is necessary, when you slip them, that the slips lie several days in the dry, to heal over the wounded parts; then plant them singly in pots of light sandy earth, place them in the shade, and moisten the earth occasionally in dry weather.

The American sort is also propagated by off-sets from the roots of the old plants in September.

CANNA, Indian flowering Reed, or Indian Shot, so called from the figure of their black seeds.

The plants are herbaceous perennials of America, preserved here in hot-houses for the beauty of their monopetalous flowers, produced in spikes upon stalks, from about a yard to six or seven feet high.

Class and order, *Monandria Monogynia*.

Characters.] CALIX, a three-leaved coloured abiding cup. COROLLA, one petal cut into six spear-shaped segments, and a two-parted nectarium. STAMINA, no filaments, but a linear antheræ, attached to one segment of the nectarium. PISTILLUM, a roundish germen under the Calix, a flat style, and linear stigma. PERICARPIUM a roundish, three-furrowed, trilocular capsule, containing globular seeds.

The species are,

¹CANNA *Indica*.

Common Indian Flowering Reed.] Canna with a tuberous, thick, fleshy root, crowned by many large, oval, ribbed leaves, a foot long, almost half as broad, pointed at both ends, and an upright herbaceous stalk four feet high, terminated by loose spikes of flowers, of different colours in different varieties.

Varieties are] Common Indian Flowering Reed with scarlet flowers—red flowering—yellow flowering—and with spotted flowers.

²CANNA *Glaucia*.

Glaucous, or Sea-green-leaved Canna.] Canna with tuberous, knotty, fleshy roots, upright stalks seven feet high, leaves a foot and a half long, and the stalk terminated by thick spikes of large, pale, yellow flowers.

These plants make a good appearance when in flower, which in England is in June, July, and August, succeeded by seeds in autumn. The plants must always be kept in pots of rich earth, to be moved to shelter in winter.

They are propagated by seeds in a hot-bed in spring; and in summer, when the plants are a little advanced in growth, prick them separately in small pots of rich earth, plunging them also in the hot-bed, giving shade, water, and fresh air, to which harden them by

by degrees till they bear it fully till October, then place them in a stove or very good green-house.

CANNABIS, the Hemp Plant.

There is but one species, an herbaceous, tall, strong annual, valuable for the bark of its stalk for making hemp for cordage and coarse cloth, and for its seed for oil, &c.

Class and order, *Dioecia Pentandria*.

Characters.] **CALIX**, male and female flowers on different plants, the males having a five-parted cup; that of the females is monophyllous, oblong, pointed, and permanent. **COROLLA**, no petals. **STAMINA**, the males have five filaments, and square antheræ. **PISTILLUM**, a small germen, two long styles, and acute stigmas. **PERICARPIUM**, it is very small, and the seed is lodged in the calix.

The species is,

CANNABIS Sativa.

Manured Hemp.] Cannabis with upright, strong, branchy stalks, six or seven feet high, adorned with large finely-digitated leaves, of about seven long narrow lobes.

Varieties.] Manured Hemp with male flowers—with female flowers, or female hemp.

Both the varieties are alike useful, as hemp for cordage, &c. but it is the female sort only, that produce the seed, for oil and other uses.

A few of these plants may be admitted as annuals in the pleasure-ground, for the variety of their majestic growth and numerous fingered leaves, sowing the seed in April where the plants are designed to remain.

In the husbandry culture of this plant, it delights in a moist, rich, deep soil, prepared for the seed, by ploughing and harrowing; and April is the time for sowing, allowing two bushels to an acre, sowing it by broadcast and harrow it in; and when the plants are come, hoe them to a foot distance, and they will be fit to pull for use in autumn.

It is pulled at two different times, the male plants generally about the middle of August, or when they have shed their farina to fecundate the females, soon after which they begin to decay, and should be pulled; but the females must stand till October to ripen their seed. Both sorts, when pulled, are bound in bundles a yard in compass, and after drying a few days, are stacked up or housed for use.

CAPITULUM, a little roundish head of flowers, a mode of inflorescence, or way of flowering, in which many small flowers or

florets are collected into a close roundish head or knob, appearing as one flower, as in *gomprena*, or globe amaranthus; and *cephalanthus*, or button-tree.

A *Capitulum* is either,

Globosum, round or globular, as in *gomprena globosa*; *dimidiatum*, half globular or hemispherical; *subrotundum*, roundish; *ovatum*, egg-shaped; *pyramidatum*, pyramidal shaped; *pedunculatum*, the florets having little foot-stalks; *foliosum*, leafy, or intermixed with leaves; *nudum*, naked, having no leaves; *hispidum*, hispid, bristly.

CAPPARIS, the Caper Shrub.

There are several species, mostly of shrubby growth; one of which is cultivated in many of our gardens as a green-house plant, and which is the true Caper-Shrub, a native of Italy, the flower-buds of which pickled, are the Capers used in sauces, &c.

Class and order, *Polyandria Monogynia*.

Characters.] **CALIX**, the cup is cut into four concave gibbous parts. **COROLLA**, four large, obtuse, spreading petals. **STAMINA**, numerous filaments, and versatile antheræ. **PISTILLUM**, a pedicillated germen, no style, but an obtuse sessile stigma. **PERICARPIUM**, a fleshy, pedicillated, unilocular berry, and numerous seeds.

The true Caper is,

CAPPARIS Spinosus.

Spinous Capparis, or True Caper-Shrub.] Capparis with shrubby spinous stalks and branches, forming a bushy head, growing three or four feet high, garnished with roundish, smooth, entire leaves, placed alternate; and from the sides of the branches many single foot-stalks, each sustaining one large, expanded, white flower.

The flower-buds, before the petals begin to expand, are proper for Capers; but for which use these are not to be expected in due quantity in this country.

This plant must be kept in pots of light sandy earth, to be placed in a green-house in winter; but it is generally more prolific in flowers, when in a hot-house during that season.

It is propagated by seed from abroad; and by layers of its youngest branches: sow the seeds in pots of light sandy compost in spring, and plunge them in a hot-bed. By layers, the young branches may be layed in spring or summer, giving each a small slit, and they will probably be rooted in a year, though they are often two before it is effected.

CAPSI-

CAPSICUM, *Capficum*, or Guinea Pepper.

This genus furnishes ornamental and useful plants, consisting of herbaceous tender annuals, and shrubby hot-house perennials, all of upright growth, with branchy heads, from two to five feet high, garnished with simple leaves, and small wheel-shaped, five-parted, white flowers, succeeded by elegant scarlet, or yellow fruit; in which consists the principal merit of the plants, being beautiful when growing, and are an excellent pickle, of a hot spicy nature.

Class and order, *Pentandria Monogynia*.

Characters] **CALIX**, a monophyllous cup, divided into five erect permanent segments. **COROLLA**, a small wheel-shaped acutely five-parted patent petal. **STAMINA**, five filaments, and connivent antheræ. **PISTILLUM**, an oval germen, slender style, and obtuse stigma. **PERICARPIUM**, the germen succeeds to a baccaceous, hollow, bilocular fruit, of uncertain figure, furnished with numerous compressed seeds.

Modern botanists allow but two real species of this genus, an herbaceous annual, and a shrubby perennial; but both of which vary wonderfully into numerous varieties, in regard to the shape, size, and position of growth of the fruit.

The species are,

¹**CAPSICUM Annua**.

Annual Herbaceous Capficum.] **Capficum** with an upright herbaceous stalk, dividing into a branchy head, about two feet high, garnished with long, broad, entire leaves; and from the sides of the branches numerous small, wheel-shaped, quinquefid, white flowers, succeeded by beautiful scarlet or yellow pods, of an indeterminate figure and size, from half an inch to half a foot long.

The varieties of this, in respect to the shape, size, and position of growth of the fruit, are very numerous, which may be divided into six classes, as those of each class are pretty permanent.

Varieties are,

Long-podded Annual Capficum.] **Capficum** with oblong, pendulous or hanging, scarlet pods—with oblong, pendulous, yellow pods—with upright, oblong, scarlet pods—with short upright pods—with divided pods—with very taper pods a span long.—All of which varieties often rise from the same seed of the Common Long-podded, Red, or Yellow **Capficum**, rarely altering from one to the other in colour, only in the size and position of growth.

Heart-shaped Capficum.] **Capficum** with roundish, heart-shaped, hanging pods—with oblong, heart-shaped, hanging pods—with heart-shaped upright pods—with round, heart-shaped, upright pods—with very large roundish upright pods, of each of which there are red and yellow colours.

Angular heart-formed Capficum.] **Capficum** with upright, angular, heart-shaped, furrowed and wrinkled scarlet pods—with upright, angular, heart-shaped, flat-topped, scarlet pods—with upright, angular, bell-shaped, scarlet pods; and the plants have generally broad wrinkled leaves.

Great Angular Pickling Capficum, or Bell Pepper.] **Capficum** with upright, swelling, fleshy-skinned, wrinkled red pods, flattened and angular at top—with hanging or pendulous pods; the pods of these varieties having a thicker, more fleshy, and tender skin, are the best of all for pickling.

Cherry-fruited Capficum.] **Capficum** with low spreading branches, leaves in clusters, and round, smooth, red, cherry shaped fruit.

Olive-shaped Capficum.] **Capficum** with an erect branchy head, and olive-shaped fruit.

Each of the above classes of varieties, though allowed to be only varieties of one common parent, yet by care in saving the seeds of the plants of each class, they continue pretty distinct or permanent, and seeds of either generally produce the like kinds, as expressed under each head.

All the varieties flower in June and July, and the pods and seeds ripen in August, September, and October.

The following are the shrubby perennial species and varieties.

²**CAPSICUM Frutescens**.

Shrubby Perennial Capficum.] **Capficum** with a shrubby perennial stem, divided into a branchy, bushy head, four or five feet high, garnished some with long narrow, and others with broad, and with purple veined leaves, and small wheel-shaped, five-parted, white flowers, succeeded by many very small fruit of different figures in different varieties.

Varieties of this are] Shrubby perennial **Capficum**, with pyramidal yellow fruit—Shrubby, pyramidal, red, barberry-fruited **Capficum**, or barberry pepper—Shrubby, conical red-fruited **Capficum**, or hen pepper—Shrubby, conical, golden-fruited **Capficum**—Shrubby, oval, very small, red-fruited **Capficum**, or bird pepper: all these, though supposed only varieties of the same species, are pretty permanent from seed, i. e. the seed of

of any particular variety, if saved with care, generally produce plants and fruit of the same kind.

All these plants, both annual and shrubby kinds, being natives of both Indies, are consequently of tender quality here. The annuals require to be raised and forwarded in hot-beds, raising them from seed in March or April, and continuing them under occasional shelter until the end of May, or beginning of June. And the shrubby kinds require almost the constant temperature of a stove, or, at least, although they will succeed in a moderate hot-bed under a deep frame in summer, where they can have occasional shelter of glasses in nights and bad weather: they must be placed in a stove in autumn, to remain all winter.

The annual kinds in general, considered as plants of ornament, are of a regular branchy growth, and very flowery; but their greatest merit is in the beauty of their fruit, which being numerous, and of different forms, sizes, positions of growths, and colours, intermixed with the green leaves and white flowers, make a fine appearance the latter part of summer, either in the borders, &c. or in pots to adorn courts or other compartments.

And for useful purposes, the young or half-grown fruit is esteemed the finest pickle in the world; all the sorts may be used for this purpose, but the great angular-podded kind claims preference.

The shrubby sorts make a fine appearance in autumn and winter in the stove, with their ripe fruit, and which often continues on the plants till spring.

The pods of all the sorts are very hot and spicy: the inhabitants of America use them in all their sauces, and the negroes devour them greedily; whence the plants have the appellation of Negro, or Guinea Pepper.

The ripe seed of all the sorts is insupportably acrid, as many have experienced by ignorantly chewing it, or by waggish persons rubbing it, for diversion, on the edges of drinking cups, &c. And the ripe pods thrown in the fire, occasion vehement sneezing, coughing, and frequently vomiting.

Propagation of all the Sorts.

All the sorts are easily raised from seed, in a hot-bed, in March or beginning of April. But first of the annual sorts.

A hot bed is to be prepared at the above time, which will serve for these and many

other tender annuals, place a frame and glass thereon, and then lay in five or six inches depth of rich light earth; the seed may then either be sown on the surface, or in small drills, or in pots, plunging them in the mould, observing in either method to cover it about a quarter of an inch deep: the plants will soon appear, observing to give air daily in common with other plants of the bed, by tilting up the light. See ANNUAL PLANTS. Also give frequent very moderate waterings; and when they are two or three inches high, having three or four leaves, it will be of much advantage to prick a quantity of them out upon another hot-bed, at four inches distance, giving water, and shade them occasionally from the sun, till rooted; after which admit air freely every favourable day, and moderate waterings two or three times a week; and by the middle of May harden them gradually to the full air, into which they should be transplanted the beginning of June, removing them with a ball of earth to each root, and place some in different parts of the flower-borders, and some in pots, giving due waterings in dry weather, till they have taken good root.

But those you intend for pickling, should be planted out in a rich warm border, in the kitchen-garden, in rows a foot and a half or two feet distance, and about fifteen inches distant in the line, giving water as above directed.

The shrubby sorts are also raised from seeds, as directed for the annuals, and the plants should be pricked singly in small pots, and plunged upon another hot-bed, under frames and glasses, giving air and water as before observed; and when they are considerably advanced in growth, remove them, with the balls to their roots, into larger pots, plunging them also in a moderate warmth under a deep frame, where they may remain to have occasional shelter of the glasses till autumn; then remove them in their pots to the stove, where their fruit will form a fine variety all winter.

CAPSULA, Capsule, one of the eight species of pericarpium, or seed-vessel.

This species of seed-vessel, *Capsula*, is a dry hollow pericarpium, of one or more elastic valves, which opens or splits, in some determinate manner, for discharging the seeds when ripe, and differs essentially from the other seven species of seed-vessel. See PERICARPIUM, &c.

A Capsule consists of one or more cells,
Locu-

[*Loculamenta*] when of two or more, they are divided from each other by partitions, having a *Columnella*, or little column of membranous substance, passing through it, to connect the several partitions with the seed. When the Capsule consists of a single cell only, it is botanically termed *unilocular*; if of two, *Bilocular*; if three, *trilocular*; if four, *quadrilocular*; if five, *quinquelocular*; if six, *sexlocular*; and if many, *multilocular*.

When it is composed of two valves, or parts that open, it is termed *bivalve*; when of three, *trivalve*; when of four, *quadri-valve*; and of five, *quinquevalve*, &c. See VALVULA.

When of different figures, they are termed *trigona*, when three-cornered; *tetragona*, four-cornered; *pentagona*, five-cornered; *turbinata*, top-shaped; *inflata*, swollen or puffed out; *ventricosa*, big-bellied; *flaccida*, feeble, flaccid; *globosa*, round, globular; *ovata*, egg-shaped; *cordata*, heart-shaped; *obcordata*, heart-shaped, with its tip downwards; *columnaris*, column-shaped; *acuminata*, pointed, tapering to a point; *teres*, slender and cylindrical; *conica*, conic-formed; *bicornis*, two-horned; *tricornis*, three-horned; *lunata*, crescent-shaped; *compressa*, flat, pressed together; *lanceolata*, lance-shaped; *subrotunda*, roundish; *oblonga*, oblong, longer than broad; *bicarinata*, two-keeled; *tricarinata*, three-keeled; *alata*, winged; *succulenta*, succulent, pulpy; *car-nosa*, fleshy; *lignosa*, woody substance; *coriacea*, leathery substance; *membranacea*, membranous, of thin dry membranes; *didyma*, twin capsules; *emarginata*, notched in the margin; *bisulcata*, two-furrowed; *trifulcata*, three-furrowed; *striata*, streaked, or superficially furrowed; *glabra*, smooth; *echinata*, (hedge hog) prickly; *tomentosa*, downy, *hispida*, bristly or shaggy; *nuda*, naked, opposed to *hispida*; *pellucida*, pellucid, or transparent; *colorata*, coloured, as in *celastrus*; *elastica*, elastic, bursting elastically like a spring, and darting the seeds from their departments with great velocity, as in some species of *impatiens*, or balsamine, and many others. See ELASTICA.

The number of Capsules succeeding each flower, is generally the same as the *germina*, or seed-bud; for the Capsule and all other seed-vessels is nothing else than the seed-bud, or germen, arrived at maturity. See GER-MEN. The seed-vessel therefore consists either of one Capsule, as in *lychnis*; two, as in

pocony; three, as in *lark-spur*; four, as in *rhodiola*, or *rose-root*; five, as in *columbine*, &c.

Capsules in splitting, or opening, are divided externally into one or more pieces, or openings, called *valves*. See VALVULA. This opening of the Capsule for discharging the seeds when ripe, is sometimes at the base, sometimes on the side, through a small hole, as in *campanula*; in some horizontally; and in some longitudinally, as in *convolvulus*; but the most usual opening, in most plants, is at the top, and burst in as many different ways as there are valves.

CARDAMINE, Ladies Smock, or Cuckoo-flower.

It comprises some low, herbaceous, flowering perennials of ornamental appearance, proper for adorning the pleasure-ground.

Class and order, *Tetradynamia Siliquosa*.

[*Characters*.] CALIX, four oval, oblong, deciduous leaves. COROLLA, four oblong cruciforme petals, the lower part erect, and spreading above. STAMINA, six filaments, four the length of the calix, and two much longer, and heart-shaped erect antheræ. PISTILLUM, a cylindric germen, no style, but a capitated stigma. PERICARPIUM, a long, cylindric, compressed, bilocular pod, opening spirally, and darting out the seeds with elastic force.

There is but one species that have claim to attention, which admits of some varieties, which are,

CARDAMINE *Pratensis*.

[*Common Meadow Ladies Smock*] Cardamine with creeping stringy roots, crowned by many winged roundish-lobed leaves, spreading on the ground, and several small stalks, a foot high, garnished with lanceolate-lobed leaves, and many flowers, in May and June.

[*Varieties of this are*] Common Ladies Smock with single purple flowers—with double purple flowers—single white flowers—with double white flowers.

The flowers of the single kind have four petals, but those of the double sorts are multiplied to the very center. The single sorts embellish the meadows in great abundance in May, from whence the double sorts were first accidentally obtained, which are highly ornamental and proper furniture for the flower-borders, and will prosper in any situation, but delights most in moist shady places, where they generally produce larger, more beautiful, and durable flowers. They are all easily

propagated by slipping or dividing the roots in autumn or early in spring, and all the slips, if not parted very small, will readily flower the following May.

CARDUUS, the Thistle.

It comprehends many hardy herbaceous annuals, biennials, and perennials, growing from one to five or six feet high, having compound flowers in ventricose, scaly, very prickly cups, but being mostly very troublesome weeds, are rarely admitted in gardens.

CARDUUS *Benedictus*. See CENTAUREA.

CARICA, the Papaw, or Pepo-tree.

This genus furnishes two curious hot-house exotics of tree-like growth, adorned with beautiful, large, divided leaves, and monopetalous and quinquepetalous, white, yellow, and purple flowers, succeeded by very large, fleshy, eatable fruit.

Class and order, *Dioecia Decandria*.

Characters.] CALIX, male and female flowers on separate plants, the males having scarce any cup, and the females a small permanent one, quinquefid at top. COROLLA, the males a funnel-shaped, long, tubular petal, cut into five narrow, blunt, revolute segments; and in the females five long spear-shaped petals turned back at top. STAMINA, ten filaments, five of them alternately shorter than the other, and oblong antheræ. PISTILLUM, an oval germen, very short style, and five broad crenated stigmas. PERICARPIUM, a large, oblong, fleshy, baccaceous, unilocular fruit, full of small oval seeds.

The species are,

¹CARICA *Papaya*.

Common Indian Papaw.] Carica with an upright, thick, soft, hollow, naked stem, rising twenty feet high, garnished upward with very large, divided, deeply sinuated-lobed leaves, spreading two or three feet on every side, and male flowers in white clusters on long foot-stalks, yellow or purple female ones growing close round the stem, succeeded by very large, fleshy, yellow, different-shaped fruit.

Varieties.] Common Papaw with male flowers—with female flowers,—With melon-shaped fruit—with gourd-shaped fruit—with pear-shaped fruit—with pyramidal fruit.

²CARICA *Pofofosa*.

Branching Surinam Papaw.] Carica with an upright branching stem twenty feet high; large divided leaves, having entire lobes, spreading widely every way; and reddish male flowers in clusters, and female ones

close to the stem, succeeded by very large, pear-shaped, yellow fruit.

Both the species produce male and female flowers on separate plants, so that the female plants only produce the fruit.

All the varieties are very ornamental in their beautiful, very large, many-lobed leaves, making a fine appearance in the stove at all seasons, and some of them flower here annually; and those of the females are succeeded by ripe fruit, which, however, seldom ripen in perfection enough to be eatable.

These plants are propagated by sowing the seed in a hot-bed in March or April, and when the plants are two inches high, prick them in separate small pots of light rich earth, and plunge them in a bark-bed; and towards autumn place them in the stove to remain, giving but very light waterings in winter, but in summer it must be frequently repeated; and as the plants advance in growth, shift them into larger pots; at each shifting be careful to preserve the ball of earth to the roots.

The plants are free shooters; and in this country they often attain from ten to twenty feet stature in three or four years.

CARPINUS, the Hornbeam-tree.

This genera furnishes two species and some varieties of hardy deciduous forest and ornamental trees, of stature from ten to seventy feet, garnished with simple oblong leaves, and amentaceous or katkin flowers.

Class and order, *Monocia Polyandria*.

Characters.] CALIX, male and female flowers apart on the same plant, growing each in a loose scaly amentum, each scale containing one flower. COROLLA, no petals in the males, but a cup-shaped six parted corolla in the female katkins. STAMINA, ten filaments, and compressed hairy antheræ. PISTILLUM, two short germens, four styles, and simple stigmas. PERICARPIUM, none; the amentum enlarges, containing at the base of each scale an oval angular nut.

The species are,

¹CARPINUS *Betulus (Vulgaris.)*

Common Hornbeam.] Carpinus with an upright strait stem from thirty to seventy feet stature, feathered from the bottom, and terminating in a very branchy head, adorned with oval, oblong, rough leaves, withering in autumn, but remain firmly attached to the branches till spring, and with plane scales to the cones, furnishing abundance of ripe seed in autumn.

Varieties

Varieties of this are] Common Hornbeam with plain green leaves—Variegated-leaved Common Hornbeam—Virginia Hornbeam growing thirty or forty feet high, closely garnished with longish, rough, deep-green leaves, falling off in autumn, and the longest cones—Oriental Hornbeam growing ten or twelve feet high, closely branching from the bottom horizontally, garnished with oval spear-shaped leaves, and very short cones.

¹CARPINUS *Ostrya*.

Ostrya, or Hop Hornbeam.] Carpinus with an upright stem, attaining twenty feet stature, terminating in a regular head, garnished with oval, oblong, rough leaves, and hop-like fruit, having inflated scales.

Variety.] Virginian Flowering Hop-Hornbeam growing thirty feet high, having long rough leaves and yellowish flowers, succeeded by hop like fruit.

All the varieties of both these species of *Carpinus* are very hardy, and will prosper in almost any soil and exposure, and of which there are varieties well adapted both for use and ornament.

As to the Common Hornbeam, it flourishes not only in good ground, but in any hungry barren soil, light or stiff, as well as in all hilly and other bleak exposed places, and is very proper to be planted as a forest tree, and for ornament in parks, either as single standards, or in clumps or large plantations; and as it retains its leaves all winter, it affords shelter to less hardy trees, and is therefore well adapted to border plantations, to break the northerly and boisterous winds.

This tree is also remarkably well adapted for hedges, either by way of ornament or shelter, for it is feathered to the very bottom, and may readily be trained to any desired height.

As the timber of this tree is valuable for many economical uses, a wood of them may be easily raised on any soil to advantage, planting four or five year old plants in rows four or five feet distance, and half that in the lines, and after a few years growth every other tree in the row may be thinned for use, so continuing to thin them as often as their heads touch.

The other sorts are also very proper for large ornamental plantations to encrease the variety, and the oriental kind is particularly well adapted for low close hedges; all the others, being also generally pretty well feathered, may also be used occasionally for that purpose.

Propagation of all the Sorts.

The common sort may be raised plentifully from seed sown in autumn in four feet wide beds, covering it an inch deep, and in the second spring the plants will rise, which in a year or two should be transplanted in the nursery, in rows two feet and half distance, and half that in the rows; and when from three to six or eight feet high, are fit for any plantation, useful and ornamental.

This sort may also be raised abundantly by layers in autumn, which will be rooted and fit to transplant by that time twelvemonth.

All the other sorts may also be raised easily from seed and layers, but the latter method is the only way to continue the different varieties distinct.

CARTHAMUS, Bastard Saffron.

The plants of this genus consists of some ornamental herbaceous annuals and perennials, producing stalks two or three feet high, crowned by yellow and blue compound flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a compound flower, having the general cup composed of many leafy scales broad at the base. COROLLA is composed of many hermaphrodite florets, divided at top into five erect segments. STAMINA, five short filaments, and cylindric tubular antheræ. PISTILLUM, a short germen, slender and simple stigma. PERICARPium, none; a single seed in each floret lodged in the calix.

The species are,

¹CARTHAMUS *Tinctorius*.

Dyer's Carthamus, or Common Bastard Saffron.] Carthamus with an upright, smooth, branchy stalk a yard high, garnished with oval, entire, spiny serrated, close-fitting leaves, and all the branches crowned by large single heads of saffron-coloured florets, extending an inch above the calix.

The flowers of this species are used in dying, and for medicinal purposes.

²CARTHAMUS *Lanatus*.

Woolly Carthamus, or Yellow Distaff Thistle.] Carthamus with bottom leaves, pinnatifid, hairy, and prickly; an upright woolly stalk two feet high, branching above, garnished with sinuated, hairy, spinous leaves, their base embracing the stalks, and all the branches surmounted by single heads of yellow flowers.

³CARTHAMUS *Cæruleus*.

Blue Perennial Carthamus.] Carthamus with upright,

upright, channelled, single stalks, two feet high; broad, spear-shaped, indented, spinous leaves; and one blue flower terminate each stalk.

⁴*CARTHAMUS Tingitanus.*

Tangier Blue Perennial Carthamus.] *Carthamus* with the radical leaves pinnated; upright slightly branching stalks a foot and half high, garnished with pinnatifid prickly leaves, and one blue flower terminates each stalk.

The flowers of all the sorts are compound, consisting of many florets in very large, leafy, scaly cups, which, in all the sorts, appear in July and August, and the seed ripens in autumn: they all succeed in the open borders, and will add to the variety of flowering plants.

The two first sorts are hardy annuals, and may be sown in March in the places where it is designed they shall flower; or if sown in a hot-bed it will forward them, so plant them out in May.

The two perennial sorts are propagated by parting their roots in autumn or spring; or by seeds in a bed of light earth in March.

CARUM, Carvi, or Caraway.

It comprises but one species, an herbaceous, umbelliferous, aromatic biennial, esteemed for its seeds for cookery and medical use.

Class and order, *Pentandria Digynia.*

Characters.] Umbelliferous flowers, each general umbel composed of ten smaller, and each floret of five petals, having five stamina, two styles, and two seeds.

The species is,

CARUM Carvi.

Common Carvi, or Caraway.] *Carum* with a long, taper, perpendicular, white root, crowned by winged, finely, many-parted leaves, on long foot-stalks, and one or two erect, channelled, branchy stems, two feet high, having all the branches terminated by umbels of white flowers in June, and ripen seeds in autumn.

It is propagated by seed in the open ground in spring or autumn, sowing them either in shallow drills, or by broad-cast, and rake them in; and when the plants are come up two or three inches high, hoe them to five or six inches distance, which in spring following will shoot up stalks, and produce flowers and seed, and the plants soon after perish.

If the seeds are sown in autumn, the plants will come up, stand the winter, and produce seeds the following summer.

CASSIA, Wild Senna.

It consists of trees, shrubs, and herbaceous plants, of American growth, adorned with winged many-lobed leaves, and quinquepetalous flowers, cultivated here in our stoves and pleasure-grounds for variety.

Class and order, *Decandria Monogynia.*

Characters.] *CALIX*, five concave-coloured deciduous leaves. *COROLLA*, five roundish, concave, patent petals. *STAMINA*, ten declined filaments, having to the three lower ones large, arched, beaked, open-pointed antheræ, which in the three upper ones are very small, and in the four side ones open without beaks. *PISTILLUM*, a taper germen, short style, and blunt stigma. *PERICARPIUM*, an oblong pod, having transverse partitions, containing roundish seeds.

The species chiefly cultivated in our gardens are,

¹*CASSIA Fistula.*

Purging Tree-Cassia of Alexandria.] *Cassia* with an upright trunk, dividing into many branches, and attains forty or fifty feet stature; winged leaves of five pair of oval sharp-pointed lobes; and from the ends of the branches long spikes of deep yellow flowers, succeeded by round hard pods one or two feet long, containing the seeds lodged in a black, sweetish, purging pulp, used in medicine.

²*CASSIA Biflora.*

Two-flowered Shrub-Cassia.] *Cassia* with shrubby stalks and branches three or four feet high; winged leaves of six pair of oblongish smooth lobes, having subulated glands between, and foot-stalks from the axillas, each supporting two flowers, succeeded by jointed plane pods.

³*CASSIA Lignifera.*

Privet-lobed Shrub-Cassia.] *Cassia* with a shrubby stalk, branching three or four feet high; winged leaves of seven pair of small spear-shaped lobes or folioles, the last pair the smallest; and from the upper parts, bunches of yellow flowers, succeeded by oblong compressed seed-pods.

⁴*CASSIA Marilandica.*

Maryland Herbaceous Wild Senna.] *Cassia* with black, fibrey, perennial roots; upright annual stalks near a yard high; winged leaves of eight or nine pair of oval oblong lobes; and the stalks terminated by loose spikes of yellow flowers, but rarely any seeds here.

The flowers of all the sorts separately are composed of five concave petals, appearing in July, and other times in summer, sometimes succeeded by pods in England.

The

C A S

The first three sorts being natives of warm climates, in this country must be potted, and retained always in the stove; the first of which, (*Cassia Fistula*) though in its native soil, Ægypt and India, it obtains a considerable stature, rarely grows higher than eight or ten feet here; so that this and the other two shrubby sorts are within the limits of our stoves, where they will flower annually and make a good appearance, and their long pods will effect a singular variety.

The above three plants should be kept in pots of light earth, plunged in the bark-bed of the stove, giving frequent waterings in summer, but more sparingly in winter.

The fourth sort (*Cassia Marilandica*) is hardy enough to prosper in a dry soil in the full air, and is proper furniture for the common flower-borders, where its flowers will make a beautiful appearance.

Propagation.

The first three shrubby sorts are raised from seeds procured from abroad, sowing them in spring in pots of light sandy earth, plunging them in a hot-bed, and when the plants are three inches high, prick them in separate small pots, plunging them also in a hot-bed or bark-bed of the stove, giving shade and water, and fresh air occasionally, in common with the other plants of that department.

The herbaceous sort is also raised from seeds procured from America, sowing them in April half an inch deep in a warm border; the plants will rise in a month, which in September or October may be planted out in the borders. Also by slipping the roots.

CASSINE, Hottentot Cherry, and Cape Phillyrea, formerly *Maurocenia*.

Of this genus are two beautiful evergreen African shrubs for the green-house, adorned with simple leaves, and clusters of white flowers.

Class and order, *Pentandria Trigynia*.

Characters.] CALIX, a small, five-parted, permanent cup. COROLLA is divided into five suboval obtuse segments. STAMINA, five spreading filaments, and simple antheræ. PISTILLUM, a conical germen, no style, but three reflexed stigmas. PERICARPIUM, an umbilicated trilocular berry, having three seeds.

The species are,

¹CASSINE *Maurocenia*.

Maurocenia, or *Hottentot Cherry*.] Cassine with a woody branching stem six or eight

C A T

feet high; suboval, thick, entire, rigid leaves; and small clusters of white flowers at the sides of the branches, succeeded by large, roundish, red, cherry-like fruit, ripening here in winter.

²CASSINE *Phillyrea*.

Phillyrea of the Cape of Good-Hope.] Cassine with a woody branchy stem, five or six feet high; oblong, sawed, stiff, opposite leaves; and small clusters of white flowers at the sides of the branches, succeeded by red berries, but seldom appear in England.

For the other species formerly of this genus, *Cassio-berry Bush*, and *Yapon*, see VIBURNUM and PRINOS.

The flowers separately of both sorts have the corolla divided into five spreading segments, and the season of flowering is July.

Both of the above species having singularly beautiful leaves, appearing very ornamental all the year, merit places in every green-house collection; they must be kept in pots of rich light earth, and continued in the open air all summer, and the green-house in winter, managing them as other woody exotics of that department. See GREEN-HOUSE PLANTS.

Propagation.

They are propagated by seeds, and by layers of their young branches.

Sow the seed in spring in pots of light earth plunged in a hot-bed, or the stove bark-bed, and when the plants are two or three inches high, prick them in separate pots, placing them also in a hot-bed, and afterwards gradually harden them to the full air for the remainder of the summer.

By layers, chuse young shoots, lay them in spring or autumn, and by autumn following they will be rooted, and fit to be planted in separate pots.

CASTRATIO, Castration of Plants.

Castrated plants are such which are deprived of the male organs, i. e. the antheræ, either by nature, or by having them cut off, as sometimes practised, to try experiments with respect to the doctrine of the sexes of plants. See SEXUS.

CATANANCHE, *Catananche*, or *Candia Lion's-foot*.

This genus furnishes hardy herbaceous ornamental plants, obtaining two feet stature, adorned with long jagged leaves, and terminated by compound blue flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, compound flowers, having

having a scaly, elegant, permanent, general cup. COROLLA, several broad, tongue-shaped, five-parted, hermaphrodite florets. STAMINA, five filaments, and cylindric pentagonal antheræ. PISTILLUM, an oblong germen, slender style, and two revolute stigmas. PERICARPIUM, none; oval seed, crowned by a downy pappus, lodged in the calix.

There are two species, a perennial and annual, the former of which only merit culture, which is,

CATANANCHE Cœrulea.

Perennial Blue-flowered Catananche.] Catananche with a fibrey perennial root, crowned by long, narrow, jagged, hairy, prostrate leaves; upright branchy stalks two feet high, garnished with small leaves, and all the branches terminated by single heads of blue flowers, having purple bottoms, golden antheræ, and silvery cups.

Variety.] Perennial Blue Catananche with double flowers.

These are very ornamental flowery perennials, both in their single and double state, continuing in flower from May till September, and succeed in the full ground in dry and somewhat sheltered borders, where they will endure many years, and produce flowers and ripe seed annually; but being somewhat tender, it is proper to keep some also in pots for shelter in winter by way of reserve.

As to their propagation, the single sort is propagated by seeds sown half an inch deep, in a bed of light earth in March or April.

Both single and double may also be propagated plentifully by slipping their roots in autumn, or early in spring, but do not slip them too small, because the larger the root, the greater number of stalks they send up for flowering.

CATERPILLARS, destructive insects in our kitchen-gardens, particularly to the cabbages and favoys in the end of summer.

The sorts which principally infest our gardens, is that yellowish-green dark-spotted Caterpillar, generated from the eggs of the white butterfly, which they are continually depositing every where, and in a few days are metamorphosed to living insects, spreading themselves surprisingly, and devour the leaves of all the cabbage tribe, first attacking the outward leaves, and, if not prevented, continue their depredations to the very heart of the plants.

When our greens, &c. are thus attacked, we have no other remedy than to pick the

vermin off repeatedly by hand, which may appear a tedious process, though, in small gardens, it may be so far practicable, as greatly to diminish their numbers, especially if undertaken before they spread considerably from their nest; but in large open grounds the plants often escape, when those in more confined places are severely attacked, and more particularly those in the corners of gardens, near walls, buildings, or hedges, which should caution us not to plant any of the cabbage tribe too near such places, nor, if possible, where much crowded with trees, for the same reason.

Besides the above sort of Caterpillar, there is a large, dark-coloured, tough-skinned sort, generated in like manner in the heart of the enclosed leaves of the autumn cabbages, favoys, &c. and detach themselves from their lodgement by eating holes through all the leaves.

This Caterpillar also burrows in the earth, to the destruction of all sorts of young plants, by eating their shanks asunder; but as it burrows just within the surface of it, may be readily found, by stirring the ground with the fingers about the place.

Our fruit-trees are also often attacked in very dry weather by Caterpillars, to the destruction of their leaves, &c. nor is there any certain method to destroy them, but by picking their nest off by hand, when practicable, before the vermin begin to spread themselves; or if they have already spread, to dash the trees frequently with water from an engine.

CATESBÆA, Lily-thorn.

There is but one species, an exotic small-leaved shrub of the hot-house.

Class and order, *Tetrandia Monogynia.*

Characters.] CALIX, a monophyllous, four-parted, permanent cup. COROLLA, one funnel-shaped, very long, tubular petal, broad and four-parted at top. STAMINA, four filaments, and oblong, erect antheræ. PISTILLUM, a roundish germen under the corolla, long style, and simple stigma. PERICARPIUM, an oval unilocular berry, containing angular seeds.

The species is,

Catesbæa Spinosa.] Catesbæa with a woody, rusty, spinous stem, branching alternately, rising eight or ten feet high; small roundish leaves in clusters; and very long, pendulent, yellow flowers, singly from the sides of the branches, succeeded by oval, fleshy, saffron-coloured berries.

This

This shrub must be always kept in pots of light sandy compost, and retained constantly in the stove.

It may be propagated by seeds, and by cuttings of its young shoots; the seeds are procured from abroad, which sow in pots of light earth, and plunge them in the bark-bed. Cuttings may be planted any time from April till July, in pots plunged in the tan-bed; and if close covered with hand-glasses, will facilitate their rooting.

CATKIN, an amentaceous flower, i. e. consists of a great number of chaffy scales and flowers, dispersed along a slender thread-like receptacle, hanging downward, and is the male flowers of the trees which produce them, as birch, beech, pine, fir, poplar, walnut, hazel, &c. See AMENTUM.

CAULESCENS *Planta*, from *Caulis* the stem, having a stem or trunk as in most plants, opposed to *Acaulis*.

CAULIS, a Stalk or Stem, the first and most common species of *Trunk*, expressive of that part of a plant or tree which arises immediately from the root, produces and supports the branches, leaves, flowers, and fruit. See TRUNCUS.

A Stalk, Stem, or Trunk, is either simple, simple-branching, or compound-branching.

As for example, simple Stalks are such as rise singly, and continue undivided from the root to the top; simple-branching Stems may be deemed such as either rise wholly undivided, but send out many side or lateral branches, or such that proceed singly to some considerable length, and then divide into branches near the top; compound-branching Stems are such that soon divide into others, and these subdivide into many *ramuli* or branches.

As Stems assume different directions, shapes, and other appearances, the botanists distinguish them accordingly by the following different terms:

Cauli integri, entire or simple Stalks, and which are either *erecta*, erect, or upright, as in most plants; *flexuosa*, of different directions at each joint; *reclinatus*, reclining, or bending archways to the ground; *volubilis*, voluble, twining or winding ascendingly round other plants or any support, either to the left, as in honeysuckle, hop and black briony; or to the right, as in convolvulus, kidney-bean, &c. *oblique*, growing asslant; *procumbens*, lying along the ground; *repens*, creeping along the ground, rooting at every joint.

Cauli Ramosus, simple-branching Stems, which

are also either erect, flexuose, reclining, voluble, &c. as above, and have different terms according to their modes of branching, as *ramosus*, branching out laterally; *ramosissimus*, very branchy; *ascendens*, the branches gradually curving upwards; *diffusus*, diffused, or very spreading branches; *brachiata*, large arms, or branches in pairs, each pair standing at right angles with those immediately above and below; *fulcratus*, supported by branches descending to the earth; *prolifer*, prolific, branching only from the apex or summit.

Caulis Compositus, compound branching Stems, and, according to their modes of branching, are termed *dichotomus*, forked or divided into others, the divisions by two and two; *subdivisus*, the divisions subdivided into many branches irregularly.

Articulatus, articulate, or jointed, composed of many joints, having knots at certain distances.

Parasiticus, parasitic, growing out of, and supported on other plants or trees, as the mistletoe.

When Stems are of different figures, they are denominated *Caulis teres*, cylindrical and taper; *anceps*, anticlinal, or two-edged; *trigonous*, three-angled; *triqueter*, triquetrous, having three plane sides; *tetragona*, square, or four-sided; *pentagona*, five angled; *polygona*, many angled.

When furrowed, smooth, rough, &c. they are *Caulis sulcatus*, deeply furrowed; *striatus*, streaked, or superficially furrowed or fluted; *glaber*, a smooth surface, opposed to *scaber*, rough, scabby, or full of rigid points or tubercles; *villosus*, hairy or shaggy; *hispidus*, hispid or bristly; *aculeus*, prickly; *spinosus*, spinous, thorny; *tomentosa*, tomentose, or downy.

Leafless and leafy Stalks are termed *Caulis nuda*, naked or leafless; *foliatus*, foliose, or ornamented with leaves, as obtains in most plants.

As to duration, Stems are either of one year's duration, *Caulis annua*; of two, *Caulis biennis*; of many years duration, *Caulis perennis*, as obtain in all trees and shrubby plants.

CEANOTHUS, New-Jersey Thea, so called from the leaves being there used as tea.

This genera retains three species of the tree and shrub kind, one for the shrubbery, one for the green-house, and one for the stove.

stove, all garnished with simple leaves, and numerous spikes of quinquepetalous white flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a monophyllous, turbinate, acutely five-parted, permanent cup. COROLLA, five roundish spreading petals. STAMINA, five subulated filaments, and roundish antheræ. PISTILLUM, a trigonal germen, cylindric semitrifid style, and obtuse stigma. PERICARPIUM, a dry, trilocular, obtuse berry, having three oval seeds.

The species are,

¹CEANOTHUS *Americanus*.

American Deciduous Ceanothus, or New-Jersey Thea.] Ceanothus with a shrubby very branchy stem about a yard high, sending out numerous reddish flexible branches from the bottom upward, garnished with oval, serrated, pointed, trinervous leaves, and all the branches and shoots terminated by clusters of white flowers.

²CEANOTHUS *Africanus*.

African Evergreen Ceanothus, or Alaternoides.] Ceanothus with a woody rough stem, and weak purplish branches, rising eight or ten feet high; spear-shaped, pointed, serrated, smooth, shining green leaves, and clusters of small greenish flowers from the sides of the branches.

³CEANOTHUS *Asiaticus*.

Asiatic Ceanothus.] Ceanothus with a shrubby branchy stem, growing four feet high; oval, pointed, close-fitting, opposite leaves; and greenish flowers in small clusters from the sides of the branches.

The flowers separately of all the sorts are composed of five small petals appearing in July, which of the first sort is sometimes succeeded by ripe seeds in England, but never any of the others.

The first species, *Ceanothus Americanus*, is a most elegant little flowering shrub, as when it flowers it appears wholly covered with bloom, and therefore is well calculated for the most conspicuous compartments of the shrubbery plantations, allowing it a moderately dry soil and somewhat sheltered situation in the fronts of the clumps.

The second sort is also worthy of a place in the green-house collection, for the beauty of its shining green leaves, appearing ornamental the year round.

The third sort is also retained in some of our stoves for variety.

Propagation.

The first sort is propagated both by seeds and layers.

Sow the seed in autumn, or as soon as they can be procured, in pots of light compost a quarter of an inch deep, placing them in a frame, to have occasional shelter in bad weather, and in spring plunge them in a hot-bed to bring up the plants, hardening them gradually to the full air in summer, but remove them in autumn, to have occasional shelter until March; then plant them out in separate small pots, or in a nursery-bed in the full ground, where they can be covered occasionally again the following winter, for they must have protection from severe frost the two or three first years of their growth.

To propagate them by layers, chuse some of the youngest branches in autumn, and lay them in the usual way, which will be rooted in a twelvemonth, and in spring after transplant them; or, if you likewise lay some of the first young shoots in June, or July, you will have the greater chance of success.

The second sort is propagated expeditiously by laying down the young shoots, either in their own pots, or others placed for the purpose; it is likewise increased by young cuttings, planted in the spring in pots, plunging them in the bark-bed, or any other hot-bed, about two months.

The third species may be raised from seeds in pots of light earth, plunging them in the bark-bed, &c. likewise by laying the young shoots, plunging the pots as just directed.

CELASTRUS, Staff-tree.

In this genus are some curious evergreen and deciduous shrubs for the shrubbery and green-house of moderate growth, ornamented with simple leaves, and bunches of whitish five-petalled flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a monophyllous unequally five-parted cup. COROLLA, five oval spreading-equal petals. STAMINA, five filaments, and very small antheræ. PISTILLUM, a small germen immersed in a very large receptacle, marked with ten channels; a short style, and blunt trifid stigma. PERICARPIUM, a trigonal, trivalvate, trilocular, coloured capsule, and oval seeds.

The species are as follow: the two first are hardy shrubs.

¹CELASTRUS *Bullatus*.

Studded-fruited Celastrus, or Virginia Evergreen Staff-tree.] Celastrus with several upright, shrubby, branching stems, four or five feet high; oval, entire, alternate leaves; and at the ends of the branches spikes of white flowers,

flowers, succeeded by three-cornered, scarlet, bullated capsules, which rarely attain perfection in England.

²*CELASTRUS Scandens.*

Climbing Staff-tree, or Bastard Euonymus.] *Celastrus* with climbing shrubby stalks, twining upon support, or about each other, twelve or fifteen feet high; oblong slightly-sawed leaves placed alternate; and greenish flowers in bunches at the sides of the branches, succeeded by three-cornered red capsules, ripening here in autumn.

The three following are green-house shrubs.

³*CELASTRUS Pyracanthus.*

Pyracantha-leaved Evergreen Celastrus, or Ethiopian Box-thorn.] *Celastrus* with shrubby, upright, irregular stems, and taper brown branches; grows a yard or more high, garnished with spear-shaped, pointed, shining green leaves, and cymose bunches of whitish-green flowers at the sides of the branches, succeeded by oval, trigonous, beautiful red capsules.

⁴*CELASTRUS Buxifolia.*

Box-leaved Evergreen Celastrus] *Celastrus* with slender, ligneous, jointed, ash coloured, spinous stems, and angular spinous branches rising eight or ten feet high; small, longish, obtuse leaves, placed in clusters irregularly; and cymose bunches of whitish flowers.

⁵*CELASTRUS Myrtifolius.*

Myrtle-leaved Celastrus.] *Celastrus* with woody, upright, unarmed stems and branches, growing twelve or fifteen feet high; oval, serrated, strong, green leaves; and long bunches of whitish flowers at the sides of the branches.

The flowers of all these species are composed separately of five oval spreading petals, and appear principally in June and July.

The first two species are proper for the embellishment of the shrubbery compartments, the first of which, *Celastrus Bullatus*, should have a dry and somewhat sheltered situation in the fronts of clumps, and they will retain their leaves most of the year; but the second sort is exceeding hardy, and will prosper any where among trees and tall shrubs, on the edge of plantations, or in woods and wildernesses, where they will mount themselves considerably, and their ripe fruit will make an elegant appearance in autumn.

The last three sorts are tender, so must be always kept in pots to have shelter in winter.

They are elegant furniture for the green-house collection. Let them be planted separately in pots of rich light mould, and ma-

nage them as myrtle and other shrubby exotics of the like temperature. See GREEN-HOUSE PLANTS.

Propagation of all the Sorts.

The first two sorts are raised from seeds in beds of light earth; also by layers of their young branches.

Sow the seeds in autumn, or early in spring, an inch deep, in a bed of light fine earth, observing, that as the plants rarely rise till the second spring, the beds all the intermediate time must be kept clean from weeds; and when the plants rise, continue the care of weeding and occasional waterings in summer; and after having two years growth in the seed-bed, plant them out in nursery-beds.

Cuttings may also be struck by aid of artificial heat.

By layers it is performed in autumn, making choice of the young wood, giving each layer a slit at a joint, and they will be rooted, and fit to transplant in nursery-rows.

The three green-house kinds may also be propagated by seeds, layers, and cuttings. Sow the seed in pots an inch deep, as soon as they can be procured in autumn or spring, and place them in a frame, to have shelter in bad weather, and occasional shade in summer; and when the plants are a year old plant them in separate pots.

Cuttings planted in pots in spring, and plunged in a hot-bed a month or two, they will readily emit roots.

Layers of the young branches in spring will be rooted by autumn.

CELOSIA Amaranth, or Cock's Comb.

This genus furnishes beautiful ornamental annuals, rising from one to five or six feet high, garnished with large oval or spear-shaped leaves, and crowned by most elegant large heads of flowers, in some resembling the figure of a cock's comb.

Class and order, *Pentandria Monogynia.*

Characters.] *CALIX*, a coloured, small, three-leaved, permanent cup to each floret. *COROLLA*, five spear-shaped, erect, stiff, permanent petals, shaped like the calix, and a small nectarium attached to the border of the germen. *STAMINA*, five filaments, and turning antheræ. *PISTILLUM*, a globose germen, erect style, and single stigma. *PERICARPIUM*, a small globular capsule of one cell, and very small roundish seeds.

There are several distinct species, all very beautiful garden-flowers; but the sort called

Cock's-Comb is the most grand and elegant of all, and which is the sort most commonly cultivated in our gardens, and the first species here described, which admits of several varieties in respect to stature, and in the colour of the flowers.

The species are,

¹*CELOSIA Cristata.*

Crested Flowered Amaranth, or Cock's-Comb.] Celosia with an upright, single, stiff stalk, from one to five or six feet high, ornamented from bottom to top with large, oval-spear-shaped leaves, on angular foot-stalks, and the main stalk crowned by a large, crested, flowery head, composed of numerous small florets.

Varieties of this are] Dwarf Cock's-Comb, from six inches to a foot and half high, with large purple heads of flowers—with red heads—with scarlet heads—and with yellowish heads.—Giant Cock's-Comb, from a yard to five or six feet high, with very large purple heads—with red heads—with scarlet heads—with yellowish heads—with white heads—and with variegated heads.—Branching Cock's-Comb, dividing into several branches, each terminated by small heads, of which are purple, red, buff-colour, &c.

²*CELOSIA Margaritacea.*

Pearly-coloured Spiked Celosia.] Celosia with an upright branchy stalk two feet high; spear-shaped, pointed, pale leaves; and the main stalk and every branch terminated by small, oblong, erect, pearly-coloured heads, forming spikes the size of a finger.

Varieties.] Pearly Celosia with oblong spikes of equal thickness—with pyramidal spikes—with entire white spikes—with white and red spikes.

³*CELOSIA Coccinea.*

Indian Scarlet Spiked Celosia.] Celosia with an upright, large, round, furrowed stalk, a yard or more high; oval gathering leaves; and the stalks terminated by several small bright scarlet heads, forming spikes.

Varieties.] Indian Scarlet Celosia with crested spikes—with incurved crested spikes—and with plumed spikes.

⁴*CELOSIA Lanata.*

Downy Clustered-spiked Celosia.] Celosia with an upright, downy, white stalk, two feet high; lanceolate, obtuse, very downy leaves; and the stalk and branches terminated by clustered spikes of flowers, having woolly stamina.

⁵*CELOSIA Castrensis.*

Dwarf Crested Spiked Celosia.] Celosia with an upright very branchy stalk a foot and half high; lanceolate acutely-pointed leaves; and all the branches terminated by crested spikes of flowers of several varieties.

The flowers of all these species, though separately very small, being exceeding numerous, and collected into large compact crested heads, or in oblong spikes, appearing as one large flower, are extremely conspicuous and elegant, and exhibit a grand appearance in a garden from July to October, particularly the first species, Cock's-Comb and varieties, which produce their flowers in very large plumes or crested heads, generally but one plume crowning each plant, in size from four or five to fifteen inches longways over the crown, and from two to five or six broad, and of proportionable depth.

Of the first species, *Celosia Cristata*, are two principal varieties, the Dwarf and Giant Cock's-Comb; the former of which, though dwarfish, is of very robust growth, leaved to the bottom, and crowned by elegant heads, and is esteemed a curiosity; but the Giant sorts make the grandest shew, as, with due culture, they attain at least a yard, but frequently five or six feet stature, decorated from the very bottom with elegant large foliage, and surmounted by wonderful large fine heads: they however require great attention to bring them to real perfection, needing the aid of three or four different hot-beds, and different-sized deep frames, to draw them up tall; but the dwarf sorts may be raised in tolerable perfection by the assistance of two hot-beds and common frames, and are therefore the properest sort for gardens that are not well furnished with hot dung and garden-frames.

The principal property of a fine Cock's-Comb is, a perfectly upright strait stem free from side-branches, well furnished all the way with leaves; and the plume of flowers large, erect, close, and regular, without any side-shoots or smaller heads.

The other four species of this genus, though not so generally known and esteemed as the Cock's-Comb kind, however, are very showey plants, and form an elegant variety among the Combs and other curious annuals, and one method of culture brings them all to perfection.

All the five species are herbaceous, and of the annual tribe, exotics of most delicate temperature, being natives of the hot parts of Asia and America, and, in their culture here, require

require to be raised and forwarded in at least two or three different hot-beds from March till June or July; that is, raising them from seed in one in March, pricking them out into another in April, and to have them very fine, transplant them into a third in May, to remain until the end of June or beginning of July, when they will have attained nearly their full stature, their heads tolerable perfection, and the weather will be then settled and warm, and should be placed abroad, where their heads will continue their full lustre till October, at which time they ripen seeds, then gradually decay, and November cold puts a total period to their existence; so that a fresh supply must be annually raised from seed in spring.

All the sorts are generally planted in pots, particularly the Cock's-Combs, to arrange in fore courts, or to move to any place where a grand shew is at any time occasionally wanted; but, if required, some may also be raised for the borders, without employing so much nicety in their culture as those you intend to pot for the grand shew; but even in this case two different hot beds is requisite, raising them in one, and pricking them out into another, to remain till June.

Propagation, General Culture, &c.

As before observed, all the sorts are raised from seeds annually in hot-beds under frames and glasses, and the proper time to sow them is the beginning or middle of March.

Observe also, as already hinted, that to have these plants as fine as possible, three different hot-beds are necessary in their culture; that is, a small one in March, wherein to sow the seed and raise the plants an inch or two high; a second in April of larger dimensions, in which to prick the plants three or four inches distance; and a third in May for a large frame, to receive them transplanted into pots, to remain until the end of June or beginning of July to grow to full size; all of which hot beds must be covered with frames and glasses, and have five or six inches depth of fine rich light earth for the reception of the seed and plants; and in the second and third hot-bed the frames must be occasionally raised or augmented in depth according as the plants shall rise in height, which is to be particularly attended to in the Giant Cock's-Comb.

Therefore, whoever intends the culture of these plants, ought to be well furnished with

hot dung, and different-sized frames and glass lights. See ANNUAL PLANTS.

The first hot-bed in March, for the reception of the seed and raising the plants an inch or two high, need not be larger than for a one-light frame, which will raise a due quantity of these and other curious annuals for furnishing any private garden, observing to make the bed two feet and half depth of dung, and directly put on the frame and glass, and in four or five days, when the rank steam and first violent heat abates, put on the mould, which must be light, rich, and dry, laying it four or five inches thick; then either sow the seed on the surface, and cover it half a quarter of an inch deep; or draw very shallow drills with the finger, sow it therein, covering it the same depth; this done, immediately put on the glass again, and tilt it a little in the middle of mild days for the evaporation of the steam, &c. the plants will appear in a few days, when air must be judiciously admitted, by tilting the upper-end of the light an inch or two high every mild calm day; and when the earth appears dry, give very light sprinklings of water in sunny weather, keep the glass close on nights, and continue to cover it with a mat; and in this manner continue the care of the plants till large enough to be pricked into another hot-bed, which will be in about three weeks.

About the middle of April therefore, or a little before or after, when the plants are an inch or two high in the seed-bed, another hot-bed for a two or three-light frame must be got ready to prick them in, as just hinted; make this bed also about two feet six inches, or a yard thick of dung, place the frame and glasses thereon, and when the burning quality of the bed subsides, mould it five or six inches deep, and next day, when the bed has imparted a due warmth to the mould, raise the plants with care from the seed-bed, and prick them in this, four or five inches distance; give a very light sprinkling of water, and directly put on the lights, and give occasional shade in sunny days till the plants are rooted, observing to admit fresh air every fine day, as above; give also occasional very light waterings every two or three days, and defend the glasses on nights with mats, as before advised; and, according as the plants advance in height, raise the frame a little in proportion: here they may grow a month or five weeks, by which time they will meet, when they must be moved into a third and final hot bed, previously

viously planting some of the best singly in pots, as hereafter directed.

Their second removal will be necessary towards the middle of May, or when the plants in the above second bed are so much advanced as to press against each other, when a third and final hot-bed should be made for one or more of the largest frames, to receive the plants in pots, observing, if you raise principally the Dwarf sorts, one of the deepest common garden-frames may be sufficient, with a little occasional raising at bottom; but for the Giant sorts, which ought to be drawn up at least three or four feet high, a deep drawing-frame, or rather a multiplying drawing-frame of two or three divisions, that the depth can be occasionally augmented, is necessary; or, in default thereof, any common frame, raised occasionally upon four posts: and for the more commodiously using these drawing-frames for the tall Cock's-Combs, the hot-bed should be sunk eighteen inches in the ground, by making it in a trench that depth; but where there is a glass-case, calculated on purpose for drawing curious annuals, this third hot-bed for the tall sorts should be made in that department. See ANNUAL PLANTS. Let the hot-bed in either method be two feet six inches at least depth of dung, which, when of due temperature, earth five or six inches thick, and next day proceed to put in the plants, observing, that such as you intend for pots, both of the Dwarf and Giant kinds, should now be potted, and the pots called twenty-fours are the proper size, one plant to each pot, being careful to take up the plants out of their present bed with a garden trowel, so as to preserve a ball of earth to the roots of each plant; place one in each pot with the ball entire, and fill up round the ball with more rich earth; give some water, and directly plunge the pots to their rims in the earth of the bed, placing them close together every way; at the same time let all the cavities between be closely filled with mould, that the steam may nowhere arise immediately from the dung, which would attack and destroy the leaves of the plants. The plants being thus all potted and plunged, put the glasses immediately on the frame, and shut them down close to draw up the heat, but raising them a little the next, and every succeeding day, that the steam may pass off: be now careful to shade the glasses in the middle of sunny days for the greatest part of the first week till the plants have taken

good root; fresh air during their residence here must also be daily admitted, by tilting one or both ends of the lights more or less in fine weather, in proportion to the advanced growth of the plants; water must likewise be afforded them twice a week, or oftener, when the weather is very hot and sunny, and every night continue to protect them from cold by shutting the glasses close, and cover them with mats; attention must also be had to maintain a constant moderate temperature of heat in the bed, by occasional moderate linings of hot dung to its sides, and by observing this, together with a proportionable supply of fresh air and moisture, the plants will now make great progress, and their heads will encrease considerably in magnitude.

Likewise observe, that according as the plants of the large sorts advance in stature, to afford them due scope to shoot, by augmenting the depth of the frame by some of the methods above observed, and as explained in the article ANNUAL PLANTS.

With regard to the Dwarf sorts, if designed to have them in their natural dwarfish growth, they must not be drawn in deep frames, &c. like the others; so that the frame containing them need be only a little raised by degrees at bottom, continuing the glasses always near the heads of the plants, to prevent their drawing up too much to stem, which, as it is not their natural growth, if they were much drawn, it would render them weak, and their heads would be but of inconsiderable size.

Towards the latter end of June the plants in general will be well advanced in growth, and the weather well settled and warm, when it is proper to begin to harden them gradually to the full air, by raising the glasses every day more and more at each end on props, and by degrees take them wholly off, and in the first week in July remove the plants in their pots fully abroad, where they are finally to remain; at the same time let each of the tall sorts be supported with a strait, firm, handsome stake, tying the stem of the plant thereto in three different places.

When placed in the open air, by no means neglect watering them in dry weather, which, when very hot and sunny, the waterings should be repeated every day; for, if not duly supplied with this article, the leaves will shrink, and the heads of the flowers become irregular.

When designed to raise any of these plants for the borders, sow the seed, as before, in the

the middle or latter end of March, and towards the end of April or beginning of May prick the plants in a fresh hot-bed six or eight inches distance, managing them as already directed until the middle of June; then transplant them with balls of earth to their roots in the borders, &c. but these will not be near so fine as those forwarded by the methods before directed.

All the sorts perfect their seeds in September and October, when great care is necessary to save it only from the most perfect heads; and be particularly careful to preserve the Dwarf and Giant sorts of the Cock's-Comb kinds separate; observing likewise, if very wet cold weather prevail at this time, the plants should be placed in a deep or raised frame, for the heads to have occasional shelter of the glasses from excessive rains.

CELTIS, the Lote, or Nettle-tree.

There are three species, all of them hardy deciduous trees, with very branchy diffused heads, garnished with simple, oblong, deeply sawed, alternate leaves, somewhat resembling those of the common stinging-nettle; and all three species are proper for ornamental plantations, and two of them also as forest-trees.

Class and order, *Polygamia Monoecia*.

Characters.] CALIX, hermaphrodite and male florets, having monophyllous, five-parted cups. COROLLA, no petals. STAMINA, five short filaments, and quadrangular four-furrowed antheræ. PISTILLUM, an oval germen, two reflexed styles, and single stigmas. PERICARPIUM, a roundish unilocular berry, containing a small roundish nut.

The species are,

¹CELTIS *Australis*.

South-European Black-fruited Nettle-tree.] Celtis with an upright large stem and very branchy head, rising forty or fifty feet high, garnished with large, spear-shaped, pointed, deeply-ferrated leaves, and greenish flowers from the sides of the branches in May, succeeded by round black fruit the size of black-berries.

²CELTIS *Occidentalis*.

Occidental, or American Purple-fruited Nettle-tree.] Celtis with an upright large stem, and very branchy spreading head, growing forty or fifty feet high; large, oval, sharp-pointed, deeply-sawed, oblique leaves; and greenish flowers from the sides of the branches in May, succeeded by purple fruit the size of large peas.

³CELTIS *Orientalis*.

Oriental, or Eastern Yellow-fruited Nettle-tree.] Celtis with an upright stem, dividing into many spreading greenish branches ten or twelve feet high; small, oval, heart-shaped, ferrated, oblique leaves; and yellowish flowers from the sides of the branches in spring, succeeded by large, oval, yellow fruit.

Varieties.] Of each sort there are varieties with bloated leaves.

The flowers of all these trees are hermaphrodites and males on the same plant; but those of both sex being devoid of petals, make no ornamental appearance, and the hermaphrodites only succeed to fruit, which, in favourable autumns, ripens tolerably well in England.

All the three species are deciduous, and of temperature hardy enough to prosper here in any exposure and soil in common with other hardy trees and shrubs.

For purposes in gardening, they are well calculated for all ornamental plantations, being finely clothed with leaves of a delightful green, which continue their verdure in a singular manner to the very last, not like most other trees of the deciduous race, whose leaves discover their approaching decay by their gradual change of colour; but these exhibit themselves a beautiful green till November, and even till their fall, about the middle or end of that month; so that they are peculiarly well-adapted for plantations, on the boundaries of spacious lawns, grand wilderness-works, and for the most conspicuous parts of parks, either placed in clumps, or as single objects.

The first and second sorts may also be employed as forest-trees in any economical plantation; for they are of free growth, and their wood being tough and pliable, is valuable for various uses.

Propagation.

The propagation of all the sorts is effected by seeds, either of English or foreign growth, which may be had of the seedsmen, and which grow freely in the full ground.

The bloated-leaved kinds, however, can only be continued by layers, cuttings, or by grafting, &c.

The seeds of the others may be sown in autumn or spring; but by sowing in autumn soon after the seeds are ripe, they commonly rise freely the following spring; and the spring-sown seeds often rise straggling, and sometimes remain a whole year before they germinate: let the seeds, however, be sown

as soon as they can be procured, either in pots, boxes, or in a warm rich border, covering them half an inch deep. When the plants appear, if cold nights prevail, afford them occasional shelter of mats; and in dry hot weather, while the plants are very small, shade in the middle of parching sunny days will be serviceable: likewise encourage them during summer by frequent waterings. In autumn and winter protect them from frost by occasional coverings, as above; and in the end of March, or in April following, prick them out from the seed-bed into another in a sheltered situation, placing the plants in rows a foot asunder; after this they require no farther care than occasional weeding, and in two or three years they will be ready for the shrubbery or other plantations.

If you at any time sow these seeds in spring, let it be in large pots, or in boxes, &c. and if the plants do not appear, remove them to the shade in summer, and shelter of a warm wall or hedge in winter, to stand till spring; at which time, if you plunge them in a hot-bed, it will bring up the plants quickly, and greatly forward them: the same may be practised to such as are sown in pots in autumn.

CENTAUREA, Centaury, Cyanus, Blue-Bottle, &c.

This genus is very extensive in herbaceous annuals, biennials, and perennials, to the amount of sixty species, mostly of upright growth, from one to five or six feet stature, dividing into branches, crowned by scaly heads of compound flowers.

A few of them are ornamental plants, and some proper for medicine; but far the greater part are plants of little or no merit.

Class and order, *Syngenesia Polygamia Frustanea*.

Characters.] **CALIX**, compound radiated flower, having a roundish scaly empalement. **COROLLA**, the disc composed of many hermaphrodite fruitful florets, tubular below, swelled and five-parted at top; and in the radius, composed of neuter or barren florets, tubular, and gradually enlarging, and unequally divided, above. **STAMINA**, five short hairy filaments, and cylindric antheræ. **PISTILLUM**, a small germen, slender style, and blunt stigma. **PERICARPIUM**, none; the seeds lodge in the calix.

The species that merit culture are as follow: the first five are very hardy perennials, perennial in root, but annual in stalk, &c.

¹**CENTAUREA Centaurium**.

Greater Purple Centaury.] Centaury with a strong perennial root, crowned by many winged very long leaves, spreading flat every way; upright branching stalks five or six feet high; a small winged leaf at each joint, and all the branches terminated by a single head of purple flowers in smooth cups.

²**CENTAUREA Glasifolia**.

Great Wood-leaved Yellow Centaury.] Centaury with a penetrating perennial root, crowned by many long, entire, erect leaves; several upright stalks four or five feet high, having a single decurrent leaf at each joint; and all the stalks terminated by a single head of yellow flowers in scaly silvery cups.

³**CENTAUREA Stæbe**.

Hoary Stæbe of Austria.] Centaury with a perennial root, crowned by many pinnatifid hoary leaves of many narrow entire segments; upright branchy stalks a yard high, a winged leaf at each joint, and each branch topped by a head of purple flowers in oblong ciliated cups.

⁴**CENTAUREA Orientalis**.

Oriental Centaury, or Great Yellow Knapweed of Siberia.] Centaury with perennial roots, crowned by pinnatifid very long leaves of many lobes; upright very branchy stalks five feet high, garnished with small pinnatifid leaves; and all the branches terminated each by a large single head of yellow flowers in ciliated cups.

⁵**CENTAUREA Montana**.

Mountain Perennial Blue-Bottle, or Blue Bachelor's-Button.] Centaury with very creeping perennial roots; many upright single stalks a foot and half high, garnished with spear-shaped, hoary, decurrent leaves; and all the stalks crowned by oblong heads of blue flowers in serrated cups.

Varieties.] Broad-leaved Perennial Blue-Bottle—Narrow-leaved Perennial Blue-Bottle—Dwarf Perennial Blue-Bottle.

The two following are perennial in root, stalks, and leaves; are rather impatient of severe frost, but will live in the full air in a dry sheltered situation.

⁶**CENTAUREA Ragusina**.

Ragusian Silvery Knapweed, or Cinara-leaved Centaury.] Centaury with a perennial root, upright branchy perennial stalks a yard high; large, pinnatifid, white, downy leaves, of many oval obtuse lobes, the exterior ones the largest; and all the branches adorned with heads of bright yellow flowers, in June, in fine hairy cups.

⁷**CEN-**

⁷*CENTAUREA Cineraria.*

White Mountain Napweed of Italia.] Centaury with perennial roots; upright, branchy, perennial stalks, near a yard high; pinnatifid, very white, downy leaves, of many narrow acute segments; and every branch crowned by a head of purple flowers in ciliated cups.

The three following are hardy annuals.

⁸*CENTAUREA Cyanus.*

Cyanus, or Annual Blue-Bottle, or Bottles of all Colours.] Centaury with annual roots; upright branchy stalks two or three feet high; narrow leaves, the lower ones indented, those above very narrow and entire; and the stalks and branches terminated by scaly heads of flowers, of various colours in the different varieties.

Varieties.] Common Blue-Bottle with blue flowers—blue and white flowers—purple flowers—purple and white flowers—flesh-coloured flowers—flesh-coloured and white flowers—violet-coloured flowers—violet and white flowers—red flowers—double blue flowers—double purple flowers—double purple and white flowers.

⁹*CENTAUREA Moschata.*

Musk-scented Oriental Cyanus, or Sweet Sultan.] Centaury with annual roots; an upright, channelled, branchy stalk, a yard high, garnished with jagged, smooth, close-fitting leaves; and from the sides of the branches many long, erect, naked foot-stalks, each supporting a single head of odoriferous flowers in round, scaly, smooth cups.

Varieties.] Sweet Sultan with purple flowers—with white flowers—with flesh-coloured flowers—with purple fistulous flowers—white fistulous flowers—with fringed flowers—*Amberboi*, or Yellow Fistular Sultan, having sawed leaves, and bright yellow fistular flowers.

¹⁰*CENTAUREA Benedicta.*

Cardus Benedictus, or Blessed Thistle.] Centaury with annual roots; very branching, hairy, reddish stalks, near two feet high; long, deeply-sinuated, hairy, decurrent leaves, having the segments ending in spines; and the ends of the branches crowned by heads of pale yellow flowers in oval, scaly, doubly-spinous cups.

The flowers of all the species and respective varieties are compound and radiated; that is, each flower is of many florets, in the centre and circumference, contained in one scaly general cup. See the *Characters*.

They all flower in June, July, and August, and mostly ripen seeds in England.

All the species, except the *Cardus Benedictus*, may be employed as ornamental plants in the common ground, where, though we have many plants of more showy appearance, they will effect an agreeable variety.

As to the perennial species, the first five are proper furniture for the compartments of extensive gardens, where many large plants of free growth and easy culture are required, as they will succeed in any common exposure and soil where moisture is not too copious. The sixth and seventh species are rather tender, so should have a perfectly dry soil and sheltered situation, otherwise will be in danger of suffering in severe winters. A plant or two of each sort may also be potted to move to occasional shelter from frost; for, as they retain their white hoary leaves all the year, they make a pretty variety in a garden.

The annual sorts, *Centaurea Cyanus*, and *Centaurea Moschata*, are pretty ornaments for the borders of the pleasure-ground. The first of these annuals grows naturally in our corn-fields, particularly the common blue sort, but which, and its numerous varieties, have also been long inhabitants of gardens, and are all very hardy, rising from seed freely in the open borders; but the other sort and varieties are natives of the East, from whence they have been long introduced into the European gardens for the beauty of their flowers, which continue in succession from June till October: the plants being somewhat tender, require to be raised in a hot-bed in spring, and planted out in May, though they will rise in a warm border in April; but these will not flower so soon as those raised in a hot-bed: the *Amberboi*, or Yellow Sultan, in particular, requires that assistance.

The tenth sort, *Centaurea Benedicta*, or *Cardus*, is considered principally as a medical herb, and its emetic property is well known.

Propagation of all the Sorts.

All the perennial sorts are propagated by seeds and parting their roots, and the sixth and seventh sorts also by slips or cuttings of their branches.

Sow the seeds of all the sorts in a bed or border of common earth in March; keep the plants clean from weeds, thin them where too thick, and in autumn following transplant them into the places of their final destination.

By

By slipping the roots; it may be done any time in open weather from October till March.

Cuttings or slips of the young side-branches of the sixth and seventh sorts, planted in a shady border in May, June, or July, will readily grow.

The annual sorts are raised from seed annually.

The *Centaurea Cyanus*, or Blue Bottle, and varieties, may be sown in the borders in patches, in the places where they are to flower, sowing several seeds in each patch half an inch deep.

The *Centaurea Moschata*, or Sweet Sultans, will also rise from seed in the common ground, sowing it in March or April, either in the places where they are to flower, as directed for the Blue Bottles, or in a warm border under hand or bell-glasses, or without, and plant them out in May or June into different parts of the borders; but if the seeds are sown in a hot-bed at the above time, it will forward the plants for transplanting in May, and they will flower near a month sooner than the others. The Yellow Sultan in particular, being rather a little tender, should be principally raised in a hot-bed, and if pricked on another in April or beginning of May, it will forward them greatly, and about the end of that month, or beginning of June, transplant them finally with balls to their roots, placing some in pots, and some in the borders.

If the seeds of the common Sultans are sown in autumn, soon after they ripen, in a warm border, the plants will come up, stand the winter, and flower the summer following sooner by a month than the spring-sown plants.

The *Carduus* may be sown in autumn or spring in the common ground; by sowing in autumn the plants stand the winter, grow stronger, and will be fit for use sooner than the spring plants. The seed may either be sown in shallow drills a foot asunder, and when the plants come up thin them to eight inches distance; or sow the seed promiscuously on the surface, and rake it in, thinning the plants as above; or they may be sown thick, and afterwards transplanted the above distance: they will shoot up to stalk in May or June, and flower in July, at which period they are in perfection to cut for use, cutting it close to the bottom; and after drying in the shade a few days, bunch it for use.

CEPHALANTHUS, Button-tree, so called from its mode of flowering.

There is but one species, a hardy, deciduous, flowering shrub of American growth, garnished with simple, oblong leaves, and small globular heads of flowers, and is very ornamental for the shrubbery.

Class and order, *Tetrandia Monogynia*.

Characters.] CALIX, aggregate flower, each floret having a monophyllous, funnel-shaped, quadrifid cup. COROLLA, many monopetalous, infundibuliforme, acute florets, collected into a round head. STAMINA, four short filaments inserted into the petal, and globose antheræ. PISTILLUM, a germen under each floret, short style, and globular stigma. PERICARPIUM, none. SEMINA, pyramidal solitary seeds, placed on a globose hairy receptacle.

The species is,

CEPHALANTHUS *Occidentalis*.

Occidental Cephalanthus, or Button-tree.] Cephalanthus with a branchy stem six or seven feet high, branching in pairs; oblong leaves by pairs and threes, having a strong longitudinal nerve, and small ones transversely; and all the branches terminated by aggregate yellowish flowers in globular heads the size of gooseberries, each aggregate composed of many funnel-shaped florets affixed to an axis in the middle.

It flowers here in July, but rarely ripens seeds in England.

This shrub deserves a place in every collection, and prospers in any common soil; but delights most in somewhat moist ground.

The propagation of this shrub is by seed in the full ground, or in pots or boxes, to move to occasional shade or shelter; likewise by layers and cuttings.

The seeds are obtained from America, and may be had of the seedsmen, which should be sown as soon as it arrives, near half an inch deep, and probably the plants will rise the first spring, though, if sown late, they sometimes do not appear till spring following; when this is the case, keep the earth free from weeds, giving occasional shade in very hot weather, and some protection from severe frost, and in spring after the plants will rise in great plenty: these the first summer should be frequently watered in dry weather, and in the autumn, or autumn twelvemonth after, according to their strength, transplant them in nursery rows two feet distance, and half that distance in the lines, and in two or three years more they will be fit for the shrubbery.

By

By layers and cuttings; the young wood, if layed in autumn, will be rooted and fit to transplant by that time twelvemonth; and cuttings of the young shoots, planted at the same time in a moist shady border, will grow.

CERASTIUM, Mouse-ear Chickweed.

It consists of several low herbaceous plants, mostly trailers, garnished with small simple leaves, and quinquepetalous white flowers, esteemed as furniture for the pleasure-ground.

Class and order, *Decandria Pentagynia*.

Characters] **CALIX**, a pentaphyllous spreading cup. **COROLLA**, five obtuse, bifid, patent petals. **STAMINA**, ten filaments, alternately shorter, and roundish antheræ. **PISTILLUM**, an oval germen, five capillary styles, and obtuse stigmas. **PERICARPIUM** is either an oval, cylindrical, or globular unilocular capsule, and many roundish seeds.

The species cultivated in our gardens are,

¹**CERASTIUM Repens**.

Repent, or Creeping Hoary Ceraſtium.] **Ceraſtium** with creeping perennial roots; many slender, trailing, branchy, perennial stalks, rooting at the joints, garnished with spear-shaped hoary leaves in pairs opposite; and numerous branchy pedunculis, each supporting one white flower, succeeded by roundish capsules.

²**CERASTIUM Tomentosum**.

Tomentose, or Woolly Linaria-leaved Ceraſtium.] **Ceraſtium** with perennial roots; many trailing, branchy, rooting, perennial stalks; oblong, narrow, very downy white leaves; and many branching pedunculis, terminated by white flowers, succeeded by globular capsules.

The flowers of both sorts are composed of five small petals, and being numerous on the plants are very conspicuous, appearing in May and June.

The plants are hardy, and prosper any where, and being natives of rocky mountains, they are proper furniture for artificial rock-work, ruins, grottos, &c. and will multiply exceedingly, by their trailing stalks rooting as they advance at every joint.

Their propagation is effected with the utmost facility, either by seeds, or slipping their rooting branches, or parting their roots; all of which may be performed either in autumn or spring.

CERASUS, the Cherry tree. See **PRUNUS**.

CERATONIA, the Carob-tree, or St. John's Bread, or *Silqua*.

It is a large evergreen exotic shrub of the green-house, adorned with pinnated leaves, and small apetalous flowers.

Class and order, *Polygamia Trioecia*.

Characters.] **CALIX**, males, females, and hermaphrodite flowers, on distinct plants, having large five-parted cups. **COROLLA**, no petals. **STAMINA**, five long filaments, and large didymous antheræ. **PISTILLUM**, a fleshy germen, long style, and capitated stigma. **PERICARPIUM**, females, a large, obtuse, compressed pod, divided by transverse partitions, each having one seed lodged in a sweetish pulp.

The species is,

Ceratonia Siliqua.] **Ceratonia** with an upright, woody, thick stem, dividing into a branchy head fifteen or twenty feet high; long pinnated leaves, of several large, thick, firm, dusky green lobes; and small purplish apetalous flowers, succeeded by large, fleshy, compressed, sweetish, eatable pods.

This shrub being a native of the southern parts of Europe, in this country requires shelter in winter; so must be kept in pots, and placed in the green house collection.

It is propagated by seeds procured from Italy, which sow in pots in the spring, plunging them in a hot-bed; and when the plants are three inches high, prick them in separate small pots, continuing them also in a hot-bed, and afford them occasional shade, water, and fresh air, to which harden them gradually in June, and in July remove them abroad to a sheltered place till October; then place them in the green-house, treating them as other shrubs of that department.

CERCIS, Judas-tree, or *Seliquastrum*.

This genus furnishes two hardy, deciduous, ornamental trees, of moderate stature, adorned with heart-shaped leaves, and clusters of pentapetalous papilionaceous-like flowers.

Class and order, *Decandria Monogynia*.

Characters.] **CALIX**, a monophyllous quinque-dentate cup, convex at bottom. **COROLLA**, five petals, resembling a papilionaceous flower; two of the petals are reflexed and form the wings, a roundish one the standard, and three, in form of a heart, form the carina, and surround the fructification. **STAMINA**, ten distinct declinated filaments, four of them longer than the rest, and oblong, incumbent antheræ. **PISTILLUM**, a narrow, lanceolate, pedicellated germen, slender style, and obtuse stigma. **PERICARPIUM**, an oblong oblique-pointed pod of one cell, and roundish seeds.

The species are,

¹**CERCIS Siliquastrum**.

Siliquastrum, or *Common European Judas-tree*.]

tree.] *Cercis* with an upright trunk, dividing into an irregular branching head, from ten to twenty feet high, garnished with round, heart-shaped, smooth leaves, on long footstalks, and purple flowers in large clusters from every side of the branches, succeeded by long flat pods.

Varieties.] With flesh-coloured flowers—with white flowers—with broad pods.

²*CERCIS Canadensis.*

Canadian Downy-leaved Judas-tree.] *Cercis* with an upright stem, branching irregularly, from ten to fifteen feet high; heart-shaped, downy, alternate leaves; and reddish flowers in clusters from the sides of the branches, succeeded by long pods.

The flowers of both these species consist each of five petals, are very numerous, and make a fine ornamental appearance in April or May, coming out with the leaves, surrounding the branches in clusters, and are often succeeded here by pods and ripe seed.

All the sorts are deciduous, and of hardy temperament.

They are choice furniture as flowering shrubs for any ornamental plantation; they are not only beautiful in their numerous early flowers, but the singularity of their leaves forms a fine variety, in assemblage with other trees and shrubs of similar growth; so should never be omitted in a collection, particularly for the most conspicuous shrubbery compartments.

Their propagation is principally by seed; for they do not succeed by layers nor cuttings. Sow the seed in March in a bed of common earth, covering it half an inch deep; the plants will appear, probably some, the same year, and the rest not till the following spring, so that the bed should not be disturbed till all are come up, being careful to clear out weeds, and give occasional waterings in summer; and in winter the shelter of mats, in very severe weather, will greatly protect the tender tops of the seedlings, which in March following transplant in nursery rows a foot apart, allowing two feet between the rows, and in about three years they will be of due size for the shrubbery.

CESTRUM, Bastard Jasmine, or *Jasminoides*.

It retains some shrubby evergreen exotics for the stove six or eight feet high, adorned with simple, oblong, thick leaves, three or four inches long, and monopetalous funnel-shaped flowers in clusters.

Class and order, *Pentandria Monogynia*.

Characters.] *CALIX*, a monophyllous, short, tubular, quinque-dentate cup. *COROLLA*, one funnel-shaped petal, with a long cylindrical tube, spreading above, and divided into five oval segments. *STAMINA*, five filaments adhering to the tube, and roundish tetragonous antheræ. *PISTILLUM*, a cylindrical oval germen, slender style, and thick obtuse stigma. *PERICARPIUM*, an oval unilocular berry, having many roundish seeds.

The species are,

¹*CESTRUM Nocturnum.*

Nocturnal, or Night-smelling Cestrum.] *Cestrum* with an upright, woody, divided, branchy stem, six or eight feet high; longish, smooth, firm leaves, veined underneath, and placed alternate; and greenish yellow flowers in small clusters, on footstalks, from the sides of the branches.

²*CESTRUM Diurnum.*

Diurnal, or Day-smelling Cestrum.] *Cestrum* with an upright, woody, divided, very branchy stem, rising eight or ten feet high; oblong, smooth, thick, firm leaves, placed alternate; and clusters of whitish flowers, sitting close to the branches.

Both these species being natives of the hot parts of America, in this country are retained in stoves.

They are evergreen, and form a pretty variety in large stoves; both sorts flower here annually, and have the appellation of Night-smelling, and Day-smelling, from the remarkable strong fragrance of their flowers respectively at these times.

They must be kept in pots of light fresh earth, watered frequently in summer, but moderately in winter.

Both sorts may be propagated by seed and cuttings, by the assistance of artificial heat; but as seeds are with difficulty procured, you may plant cuttings of the side-shoots five or six inches long, in pots of light earth, any time in summer, plunging the pots in the bark bed, and give occasional shade and water.

CHAMÆEROPS, Dwarf Palm, or *Palmetto*.

It consists of one species, an acaulis perennial exotic, with large, palmated, fan-shaped leaves, and spathaceous flowers; a native of Spain, and retained here in our stoves for variety.

Class and order, *Polygamia Dioecia*.

Characters.] *CALIX*, male and hermaphrodite

phrodite flowers on distinct plants, having a compressed spatha, protruding a branching spadix of many florets, each having a triphylous cup. COROLLA, a branching spadix of many erect florets, each divided into three inflexed parts. STAMINA, six compressed filaments, and narrow twin antheræ. PISTILLUM, three roundish germina, and three permanent styles, and acute stigmas. PERICARPIUM, three unilocular berries, each having a single seed.

The species is,

CHAMÆROPS Humilis.

[Dwarf Pa'm, or Palmetto.] *Chamærops* with a spreading root, sending up frondose spinous foot-stalks, elevating at top; large palmated folded leaves, from ten to eighteen inches long, and near a foot broad, of many foldings, opening like a fan, and divided at top like the fingers of a hand; and between the leaves arises a spatha, protruding a branching spadix of flowers.

This plant rather requires protection of a stove while young, but when older, it will prosper in the full air in summer, and in a green-house in winter, and must always be kept in pots of light sandy earth, frequently watered in summer, but moderately in cold weather.

It may be propagated by seeds, and by slips from the head of the root. The seeds are procured from abroad, which sow in pots of light sandy earth, and plunge them in a hot-bed, giving occasional waterings; and by autumn or spring following the plants will be fit to be pricked in separate pots. By slips the crown of the roots sometimes afford off-sets, which, if separated with fibres, planted in pots, and plunged in a hot-bed, will readily grow.

CHARACTERS. The description or general character of every genus of plants, drawn from the fructification, or all the parts of the flower.

The term *Character* is applied only in describing the *genera*, and never extended to the *species*; that of the *genus* being always founded on the parts of the fructification, as being invariable; and the description of the *species* of each genus, is from striking circumstances of the root, stem, leaves, buds, and mode of flowering, &c. all of which are often very different in different species of the same genus; but as the flower or fructification being unchangeable, that, and none other, is to be employed in establishing the

genus, and therefore the *characteristic* mark of each genus is to be fixed from the figure, situation, connection, number, and proportion of all the parts of the flower, as the *calix*, *corolla*, *stamina*, *pisillum*, *pericarpium*, and the *semen*, or seed; which parts are defined to be the fructification of all vegetables, being a temporary but invariable part appropriated to generation, terminating the old vegetable, and furnishing seed to begin the new; and which *characteristic* marks being constant throughout the species of every respective genus, and every genus invariable in itself, the flower is now universally established as the only proper basis from which to draw the Characters, to distinguish all the numerous genera of plants.

But before the invention of a regular systematic method, Characters were drawn from any, or all the parts of the plant indiscriminately, as the root, stem, leaves, buds, and general habit; a circumstance so variable and uncertain, as explains the great confusion that so long obtained in botany; such descriptions being only to distinguish the different *species* of a *genus*.

The Characters therefore of every genus are founded on the parts of the flower, which being destined for the reproduction of the plant and fruit, must necessarily be most constant; and all the species of every genus, however different in their external habit, which is often very considerable, yet they perfectly agree in their fructification: thus, for example, what apparent difference there is betwixt the cabbage, cauliflower, broccoli, and turnep! and yet are all species and varieties of the genus *Brassica*, perfectly agreeing in their generical Characters. See GENUS and SPECIES.

CHEIRANTHUS, Wallflower, and Stock-Gilliflower.

The plants are of the flowery tribe, and consist chiefly of herbaceous shrubby biennials, perennials, and annuals, of upright branchy growth, from one foot to a yard high, adorned with longish narrow leaves, and long erect spikes of numerous, four-petalous, very ornamental flowers.

Class and order, *Tetradynamia Siliquosa*.

Characters.] **CALIX**, four spear-shaped, concave, erect, connivent leaves. **COROLLA**, four roundish petals, placed in form of a cross. **STAMINA**, six parallel filaments, two rather shorter than the other, and erect acute antheræ. **PISTILLUM**, a long, prismatic, tetragonous

tragonous germen, the length of the stamina, exceeding short style, and thickish, divided, reflexed, permanent stigma. PERICARPIUM, a long compressed filiqua, or pod, containing many compressed seeds.

There are many species; but those of most merit are, those celebrated beautiful plants, well known by the vague names of Wallflower and Stock-Gilliflower, so valuable as ornamental garden-plants, both for the elegance and delightful fragrance of their numerous flowers, and of which modern botanists allow but three distinct species; that is, two biennials, or sometimes perennials, and an annual, each of which, however, admits of many fine varieties.

The Wallflowers are very distinguishable from the Stocks by their narrow, smooth, green leaves, those of the Stocks being broader, thicker, and mostly of a hoary whitish hue.

The species of our gardens are,

¹CHEIRANTHUS *Cheiri*.

Cheiri, Common Cheiranthus, or Wallflower.] Cheiranthus with ligneous, long, tough roots; an upright, woody, abiding stalk, divided into many erect angular branches, forming a bushy head from one to two feet high, closely garnished with spear-shaped, acute, smooth, green leaves, and all the branches terminating in long erect spikes of numerous flowers, which, in different varieties are Yellow, Bloody, White, &c.

Varieties of this are,

Common Dwarf Yellow Wallflower—having a low bushy stem ten or twelve inches high, and smallish yellow single and double flowers.

Large Yellow Wallflower—having a branchy stem eighteen inches or two feet high, and large yellow single and double flowers.

Large Yellow Bloody Wallflower—having a branchy stem from about fifteen inches to two feet high, and yellow blood-spotted single and double flowers.

Bloody Wallflower—having a branchy stem fifteen or eighteen inches high, and large blood-coloured single and double flowers.—This variety, in its true bloody state, is esteemed the most beautiful of all the Wallflower tribe, and its flowers are the largest.

White Wallflower—having a very branchy greenish stem about a foot high, narrow shining green leaves, and pure white single and double very fragrant flowers—with cream-coloured single and double flowers.

This sort being rather tender, should have

a dry soil and warm situation, where it will often flower, both in the spring, and in autumn and winter.

Narrow-leaved Straw-coloured Wallflower—having a bushy stem a foot high, very narrow leaves, and long close spikes of straw-coloured single and double almost scentless flowers.

Variegated-leaved Yellow Wallflower—having a branchy stem twelve or eighteen inches high, garnished with gold-striped leaves, and yellow single and double flowers—silver-striped leaves, and yellow flowers.

Winter Wallflower—having a branchy stem a foot or fifteen inches high, and white or yellow single flowers, appearing the beginning of winter, often continuing, if mild weather, till spring, when they exhibit a general bloom as the other varieties.

All the above varieties of this species (Wallflower) are robust, bushy, evergreen, hardy biennials and perennials, very flowery plants, flowering principally in April, May, and June, often exhibiting their flowery spikes two or three feet high; the plants growing freely in any common soil and open exposure, are great ornaments to the compartments of the pleasure-ground. The Double are in most esteem, and more particularly the Double Bloody sort; but all the varieties effect a fine diversity, and the Singles of each sort afford plenty of seed for propagation, and from which both single and double flowered plants are produced; and all the sorts may also be increased by slips, cuttings, and layers, in a shady border in May or June, which is the only method to continue the fine double kinds.

²CHEIRANTHUS *Incanus*.

Hoary Cheiranthus, or Stock-Gilliflower.] Cheiranthus with ligneous, long, naked, white roots; an upright, strong, woody, abiding stem, from one to three feet high, branchy at top, adorned with long, spear-shaped, obtuse, hoary leaves; and the top of the stalk, and all the branches, terminated by erect spikes of flowers, from one to two or three feet long, of different colours, in different varieties.

Varieties of this are,

Red, or Queen Stock-Gilliflower—having a robust stem a foot high, very branchy and bushy at top, every branch terminated by an erect close spike of pale red single and double flowers—bright red single and double flowers—variegated red and white single and double flowers.—This sort and varieties are remarkable for their prolification in many double-flowered.

flowered plants, from seed, and that, if sown early in spring, it flowers a little the same year towards autumn, which is a peculiar merit in this sort, because the double flowers of the same year's seedlings, discovering themselves at that time, we take them up with good balls to their roots, and pot them, to move to occasional shelter from frost, whereby they flower earlier, and much stronger in spring, than those that are fully exposed, especially in severe winters, when the Stocks in general are sometimes considerably cut.

Scarlet, or Brompton Stock-Gilliflower—having a strong unbranching stem from one to three feet high, crowned by a cluster of long thick leaves; and from the centre an erect flower-stalk two or three feet long, issuing forth several side-branches, all of which, and the main stalk, forming beautiful erect spikes of large scarlet single and double flowers.

This in its double state makes a most superb appearance, and is the grandest of all the *Cheiranthus* kind, the flowers being often as large as small roses, numerous and closely placed, disclosing themselves in successive order upward, according as the spikes gradually advance in height, which, when at full length, frequently show the plant upward of four feet high, exhibiting a full bloom five or six weeks.

Purple, or Twickenham Stock-Gilliflower—having a thick stem a foot and half, or two feet high, very branchy upward, and all the branches terminated by erect spikes of purple single and double flowers—purple blood-spotted single and double flowers—variegated purple and white flowers.

White, or Shrubby Stock-Gilliflower—having a shrubby firm stem, from a foot to a yard high, divided and subdivided into many short branches, forming a bushy shrub-like head, very shining green leaves, and all the branches terminated by erect spikes of pure white single and double flowers—whitish flesh-coloured flowers—whitish purple flowers—whitish red spotted flowers.—This sort and varieties are remarkable for becoming shrubby, and of several years duration in a dry soil, and for affording many double-flowered plants from seeds.

All the above varieties of this species (*Cheiranthus Incanus*) are hardy, evergreen, very flowery, ornamental biennials and perennials, and grow freely in the open ground, and are great ornaments to the pleasure-ground in May, June, and July, exhibiting their bloom from two to four feet high: the double kinds

are singularly beautiful; but all the sorts form a fine variety, and the singles produce plenty of seed in autumn, and from which both single and double-flowered plants are annually produced.

³*CHEIRANTHUS Annuus.*

Annual Stock-Gilliflower, or Ten-Weeks-Stock.] *Cheiranthus* with an upright, woody, smooth stalk, divided into a branchy head, a foot or fifteen inches high, garnished with spear-shaped, blunt, a little indented, hoaryish leaves, and all the branches terminated by long erect spikes of numerous flowers, of different colours in different varieties.

Varieties of this are,

Common Hoary-leaved Ten-Weeks-Stock—having hoaryish leaves, and purple single and double flowers—red single and double flowers—white single and double flowers.

Prussian Wallflower-leaved Ten-Weeks-Stock—having smooth, bright, green leaves, and pure white single and double flowers—purple single and double flowers.

All these varieties prosper in the full ground, and flower beautifully from July till autumn, and the singles afford abundance of seed, and from which both single and double kinds are always produced; for being annual, they can only be continued by seed sowed annually in spring.

⁴*CHEIRANTHUS Maritimus.*

Maritime Dwarf Annual Cheiranthus, or Virginia Stock-Gilliflower.] *Cheiranthus* with slender, herbaceous, very branchy, diffuse stalks, six or eight inches high; small, spear-shaped, close-fitting leaves; and all the branches terminating in short loose spikes of many small, purple, single flowers, having eminent antheræ.

The flowers of all these four species, and numerous varieties, are produced in erect spikes, from half a foot to a yard long, each spike having many flowers, especially all those of the first three species; and those of the doubles are generally the most numerous, largest, more closely-placed, and of longest duration. The single flowers are composed separately of four broad petals, see their *Characters*; but in the doubles, the petals are multiplied in many series to the very centre, to the total exclusion of the fructification, so consequently afford no seed; the singles however afford plenty, and from which, plants of both sorts are obtained. The double-flowered kinds are very distinguishable at the first appearance of the flower-bud, which is more robust, larger, and swelling, than those of the singles.

The

The first and second species, *Wallflower*, and *Stock-Gilliflower*, and all their respective varieties, may be considered both as biennials and perennials, with abiding stalks, garnished with leaves the year round, and very profuse in most fragrant flowers. Considered as biennials, the plants being raised from seed in spring, attain nearly their full growth by autumn, stand the winter, and in spring following shoot up their flower-spikes, which gradually advance in height, and the flowers continue opening till June, and which are succeeded by ripe seed in July, August, and September; soon after which the plants frequently perish, especially when growing in rich moist ground; or, if they survive another year, they generally assume a dwindling growth, become straggling and irregular, and flower weak and inconsiderably. As to their perennial property, being raised as above, and planted in a dry, rubbishy, gravelly, or any poor lean soil, they generally effect a stunted growth, become shrubby and perennial, of several years duration, and flower annually, as is evident by those which grow naturally out of the crevices of walls, ruins, and old buildings, in many parts of England, particularly the Wallflowers; hence they derived the name; though the Stocks will also grow in the same manner, with short, stunted, stocky stems; hence we suppose they obtained the appellation of stocked, or Stock-Gilliflower: however, when cultivated either in good or bad earth, and whether of two or more years duration, most of the sorts, both Walls and Stocks, generally flower strongest, and in greatest beauty, the first year of flowering; therefore, to have a constant succession of plants to flower in perfection, a supply must be annually raised from seed in April or May for next year's bloom, though the Wallflowers may be increased by planting slips of their young shoots in May, which is the only method to propagate the double kinds; for the Walls are not very prolific in doubles from seed: the stocks may also be continued by slips, but these never succeed near so well as the Walls; besides, the different varieties of Stocks are often very profuse in double flowered seedlings, which renders the other practice unnecessary; and the Queen Stock, White Stock, and the Twickenham Purple, frequently have one third, or half their seedlings double; but the White Stock most of all.

All the varieties of the above two species prosper freely in the open border, in any

common soil and open exposure, though, when growing in rich moist land, they, acquiring a luxuriance of growth, are more liable to injury, from the power of severe frost, but more particularly the stocks; and in both species the double varieties are more liable to suffer than the single kinds, so that some of the finest doubles should always be potted, to move to occasional shelter of a deep frame, to be covered with glasses or mats, in time of severe weather in winter, but must be fully exposed in all mild weather.

The third species, *Ten-Weeks-Stock* and varieties, is but of one summer's duration, rising from seed in spring, and perishing at the first attack of hard frost in winter. All the varieties of this species are of hardy growth, and most beautiful annuals, very profuse in most elegant spikes of flowers great part of summer and autumn, and the plants prosper in the open borders, and make a fine appearance, particularly the double kinds; and all the varieties are easily raised from seed in the common ground in spring, or may be forwarded in a hot bed, and, in either method, being planted out in the borders in May or June, they flower in July, and by two or three different sowing, at a month or six weeks interval, from February to May, a succession of full blowing plants may be obtained from July until December.

The fourth sort, *Cheiranthus Maritimus*, is but of few months duration; it, however, considering its diminutive stature, is a very flowery plant, and proper to sow in patches, to adorn the fronts of borders, which, by a repetition of three sowings from February to May, will afford a succession of bloom from June till October.

It is also some times sowed to form a summer edging in small gardens, which, during its bloom, is very pretty.

Propagation of the first two Species.

The two first species, and all their respective varieties, are propagated plentifully from seed, in the common ground in spring, for transplantation; and from the seedlings both single and double-flowered plants are obtained; but the Stocks are considerably more prolific in doubles than the Walls: however, when fine doubles of these are obtained from seed, &c. they may be multiplied at pleasure by slips of their young side shoots early in summer; for all the sorts of Wallflowers, both single and double, grow freely by slips: but

but as to Stocks, although they will also grow by slips, they do not make near such progress as the others, nor do they ever grow freely, nor make such thriving plants; but this is no great loss, since the seedlings seldom fail to afford great plenty of doubles.

First, of raising both species from seed, observing that the plants raised one year flower the next.

The seed of all the varieties may be had cheap enough of all the nurserymen; but the great article is to procure such that have been saved from the finest of each respective variety. See *Saving the Seed*. The time for sowing is as follows: the Wallflowers may be sown any time in April; though in very rich ground, from about the 20th of that Month to the 15th of May is the most proper time to sow both sorts, for if sowed sooner in a rich warm soil, the plants are apt to acquire a too great luxuriance of growth, and thereby subject to suffer by severe frost and excessive wet in winter. For the reception of the seed choose a spot of undunged light earth, in a quite open situation, and, as soon as dug, sow the seed on the surface, each sort separate, and rake it in light and evenly. The plants will rise in a fortnight, when, if dry weather prevails, give frequent waterings, and in July, or when they are about three inches high, a quantity of the stoutest should be thinned out in a moist time, and planted singly in different parts of all the borders, and the other compartments of the pleasure-ground, where it is designed they shall flower, which all the sorts will effect the following spring and summer. Or the Wallflowers may be pricked in nursery-beds nine inches distance till October, then finally transplanted with balls to their roots; though where there is room in the borders at the time above-mentioned, it is most adviseable to plant out most of these plants at once while young, where they are to remain, because they do not succeed so well by removals, especially the stocks, as having long sticky roots, ill furnished with fibres; but the plants of both species, when removed large, unless with good balls, never take root so freely, nor establish themselves so firmly, nor are of so long duration, as when planted out finally at the period of growth first advised.

The Wallflowers however succeed much better by removals than the Stocks, their roots being more fibrey, and upon particular occasions might even, when of pretty large

growth, or when just ready to bloom, be removed where wanted with balls to their roots; but those of the Stocks being so scanty of small fibres, that the plants, when large, rarely rise with good balls, without the greatest care in digging wide and deeply round them.

Where the above two species are raised for sale, as is greatly practised by the setting-gardeners in the vicinity of London, the plants from the seed bed are pricked or planted out in nursery-beds, in rows nine inches or a foot distance, and the same distance in the lines; and if they here assume a luxuriance of growth, they sometimes transplant them again about the end of August into other beds, as above, especially the Wallflowers, to check their luxuriance, and promote their growing bushy, to render them more marketable; for vast quantities of these plants are brought to Covent-Garden, and the other gardeners markets in London, in the spring of the year, for sale, just as they begin to shew bloom, when the colours and properties of the flowers are discoverable, all brought with small balls of earth to their roots, for they will not buy them without, and are there sold, the single kinds for a shilling or eighteen-pence per dozen, but the fine doubles are commonly brought in pots, and one plant of which often fetches as much, or more, than a dozen of the others.

If it is designed to cultivate any of these plants upon walls, ruins, or rock-work, for variety, it is most eligible to sow the seed where the plants are to remain, sowing it in the crevices in autumn or spring, covering it with any kind of dry earth a quarter of an inch deep, and leave it to nature, where the plants will come up, flower, and scatter their seeds, and propagate themselves, and endure for years.

If seeds of any of the sorts are sown in any rubbishy or poor soil, and the plants thinned and permitted to remain unremoved, they are commonly of longer duration than those that are transplanted.

When intended to show a bloom of any of the double seedlings in pots, they may be potted with balls to their roots as soon as they shew their double flower-buds; but as the Stocks remove rather badly when large, and as they are considerably more prolific in doubles than the Walls, you may also, at the time of transplanting from the seed bed, plant some in large pots, three or four in a pot, and it is probable one or more in each pot may prove doubles,

doubles, particularly the Queen, Purple, and White Stock; so that as soon as the doubles are discoverable, cut the others off close to the bottom.

Propagation by Slips.

The propagation by slips or cuttings is practised principally for multiplying the fine double kinds, but chiefly for the Wallflowers, for the reasons already hinted: the time of year for this work is April, May, and June, though they generally afford the best slips in May; these are the young side-shoots without flowers, three, four, or five inches long, which slip or cut off close to the branches, divest them of the lower leaves, and plant them in a shady border six inches distance, and two, three, or four inches deep, according to their length, giving occasional waterings in dry weather, where they will readily form roots, shoot at top, and make good plants by October, when the fine sorts should be each planted separately in pots, to move to occasional shelter of a frame during winter, covering them only in time of hard frost, and they will all flower the spring following.

All the varieties may also be propagated by layers of their young pliable branches in May and June, as practised for carnations; but the raising them from slips is the more ready and expeditious method, and generally productive of the best plants.

To continue a stock of handsome strong flowering plants of all these sorts, always raise a supply annually both from seeds and slips, &c. for, although the plants sometimes live two, three, or more years, they always exhibit the finest bloom the first season of flowering.

All the double plants that are retained in pots should be moved to a place of occasional shelter in winter, either in a deep frame, or plunge them in a warm border, and arch them over with hoops; and in frosty weather, if in a frame, cover with the glasses, or, if under arches, with mats, and with long litter over either of these, when the frost is very severe.

Propagation of the third and fourth Species.

The third species, *Ten-Weeks-Stock*, is propagated by seed for transplantation, any time from the middle of February to the middle or end of May; and by three different sowings in that period of time, you will obtain plants, exhibiting a constant bloom from July till almost Christmas.

The seed will grow freely on a warm border, especially those sown after the middle of

March; but to have the plants as forward as possible, I should advise the first sowing to be in a moderate hot-bed, or, in default thereof, in a frame, or under a hand-glass, for shelter on nights during the cold weather, sowing it on the surface, and either rake it in lightly, or cover it with fine earth a quarter of an inch deep; and when the plants have several leaves, about two or three inches high, take the opportunity of moist weather to plant them out at once into the borders or places where you design they shall flower, giving a little water, and they will soon take root, and grow freely without farther trouble.

If you design to exhibit a blow of these plants by themselves, plant them in four feet wide beds, in rows a foot asunder, allowing the same distance in the rows.

When it is intended to have a shew of double kinds in pots, then either at the time of planting out, set three plants in each pot, and as soon as they show bloom, it is probable one or more of the three will be double, when the others may be cut away, not pulled up, because of disturbing the roots of the remaining ones; or, if the plants are in beds, some of the doubles, as soon as discoverable, may be taken up with good balls, and plant one in each pot, give water, and place them in the shade a week or two.

The fourth sort, *Dwarf Virginia Stock*, is raised from seed, sown a quarter of an inch deep in the places where the plants are to remain, either in patches in the fronts of borders, or as an edging, as already observed.

Saving Seed of all the Sorts.

All the sorts afford seed plentifully in their single state; the doubles none at all; and it ripens abundantly in June, July, and August.

In order to continue a succession of the finest sorts of the three first species and varieties, you ought to be choice in the plants from which to save seed: the largest plants therefore of each respective variety of singles, and with the largest flowers of the deepest or brightest colours, are to be marked; and where you discover any with flowers that exhibit a tendency towards a semi-double state, these are also particularly to be chosen; that is to say, the singles having naturally but four petals, but sometimes here and there one will sport, and have five, six, or more, approaching to half doubles; and seeds saved from such kinds, are always more prolific in double-flowered plants than that of the entire single flowers: likewise good single plants,

plants, growing close to, or very near doubles of the same kind, are also proper to mark for seed; and all bad kinds, particularly singles, growing near the chosen seed-plants, should be cleared away. By observing the above hints, you cannot fail of continuing an annual shew of these flowers in their greatest perfection.

According as the seeds ripen, cut off the branches in dry weather; tie them by the ends in small bunches, and hang them up in a dry but airy place, and when properly dried rub out the seed, and put it up in paper bags till spring.

CHELIDONIUM, Celandine, and *Glaucium*, or Horned-Poppy.

This genus furnishes hardy herbaceous perennials, biennials, and annuals, of the flowery tribe, obtaining from about eighteen inches to a yard in stature, ornamented with large divided leaves, and large, four-petalous, yellow and scarlet flowers.

Class and order, *Polyandria Monogynia*.

Characters.] **CALIX**, two oval, concave, caduous leaves. **COROLLA**, four large, roundish, plane, spreading petals. **STAMINA**, numerous filaments, and oblong, compressed, twin antheræ. **PISTILLUM**, a cylindrical germen, no style, but a headed bifid stigma. **PERICARPIUM**, a cylindrical bivalvular pod, having many seeds.

The species of note are,

¹**CHELIDONIUM Majus**.

Greater Common Perennial Celandine.] **Chelidonium** with a thick knobby root; upright, round, branching, hairy stalks, two or three feet high; large, many-lobed leaves; and at top of the stems and branches umbellated foot-stalks, supporting large yellow flowers.

Varieties.] **Greater Celandine** with jagged leaves, and double yellow flowers—with striped jagged leaves.

²**CHELIDONIUM Glaucium**.

Glaucium, or Biennial Chelidonium, called Horned-Poppy.] **Chelidonium** with upright, robust, round, smooth stalks, divided into many branches two feet high; pinnatifid lower leaves, those above lobated, and their base embrace the stalks; and from the axillas of the leaves, single foot-stalks, supporting each one large yellow flower, succeeded by long horn-shaped pods nine or ten inches in length.—Hence the appellation Horned-Poppy.

It flowers in June and July, and ripens abundance of seeds, and being a biennial, dies soon after.

³**CHELIDONIUM Corniculatum**.

Corniculated Annual Chelidonium, or Scarlet Horned-Poppy.] **Chelidonium** with upright rough stalks half a yard high; large, pinnatifid, finely-jagged, many-pointed, hairy, close-fitting leaves; and scarlet flowers of short duration, succeeded by long corniculated, or horn-shaped, pods.

The flowers of all these species in their natural state are composed of four large, roundish, spreading petals; but in the double kind the petals are numerous.

They are all very hardy plants, and prosper in any common soil.

The first species grows wild in shady lanes, sides of banks, and such-like uncultivated places; is valuable in medicine, but in its common state is rarely admitted into gardens. The double-flowered variety, however, merits culture as a flowery perennial for large borders, and may be multiplied abundantly by dividing the roots in autumn or spring.

The second sort, *Chelidonium Glaucium*, merits notice both as a flowery biennial, and for the singularity of its long horned pods; it inhabits the sea coasts, but has been long admitted in gardens, and grows freely in the borders, or in rock-work, &c. It is propagated plentifully by seed in autumn or spring, sowed either where the plants are to remain, or for transplantation; they come up one year, flower the next, and soon after perish; so must be raised annually from seed.

The third sort will form a variety in the borders among other hardy annuals, and should be sowed in February or March a quarter of an inch deep, in patches where they are to remain.

CHELONE, *Chelone*.

It consists of three herbaceous flowery perennials, with upright stalks two feet high, decorated with spear-shaped leaves, and beautiful spikes of monopetalous, ringent, different-coloured flowers, in autumn.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX**, a monophyllous, quinquepart, permanent cup. **COROLLA** is monopetalous and ringent, with a short tube, swelling at the mouth, the upper lip obtuse and indented, the under one slightly trifid. **STAMINA**, two long and two short filaments, inclosed in the back of the corolla, and incumbent antheræ. **PISTILLUM**, an oval germen, slender style, and blunt stigma. **PERICARPIUM**, an oval bilocular capsule, and numerous, roundish, bordered seeds.

E c

The

The species are,

¹*CHELONE Glabra.*

Smooth Acadian Chelone.] Chelone with thick very creeping roots; many upright, smooth, channelled stalks, two feet high, garnished with spear-shaped, pointed, serrated, close-fitting leaves, in pairs opposite; and all the stalks terminated by close spikes of flowers, of different colours, in different varieties.

Varieties.] Smooth Chelone with white flowers—with rose-coloured flowers—with red flowers—with purple flowers.

²*CHELONE Hirsuta.*

Hairy Virginian Chelone.] Chelone with spreading roots; upright very hairy stalks two feet high, garnished with spear shaped, hairy, opposite leaves; and all the stalks terminated by spikes of flowers, of different colours, in different varieties.

Varieties.] Hairy Chelone with white flowers—with blue flowers—with red flowers—with purple flowers.

³*CHELONE Penstemon.*

Penstemon, and the Asarina Erecta of Miller.] Chelone with upright branchy stalks a foot and half high, adorned with spear-shaped, pointed, opposite leaves, their base embracing the stalk, and short loose spikes of purple flowers from the forks of the branches.

The flowers of all these species and varieties are of the ringent or gaping kind, many upon each spike, which in all the varieties appear from September till November, and are sometimes succeeded by ripe seeds in England.

They are all very hardy, and grow freely in the open ground, in any soil and exposure.

They are choice furniture for the pleasure-ground, particularly the two first sorts and varieties, their flowers exhibiting a very ornamental appearance for two months in autumn, after the principal bloom of most other flowers are past; and being of different colours, they form a fine variety with each other, and the plants may be readily encreased at pleasure, to furnish all the different compartments abundantly.

The propagation of the two first sorts, and all the varieties, is by roots, which multiply exceedingly, and may be parted in autumn, or early in spring.

The third sort being rather biennial, must be raised annually from seed, which, if sown in autumn as soon as ripe, the plants will readily rise the following spring, and in June or July may be planted out in the borders.

CHENOPODIUM, Goose-foot, or Wild Orach.

This genus retains hardy herbaceous plants for culinary and ornamental uses, and shrubby evergreens for the green-house.

Class and order, *Pentandria Digynia.*

Characters.] CALIX, five oval, concave, permanent leaves. COROLLA, no petals. STAMINA, five filaments, and roundish didymous antheræ. PISTILLUM, an orbiculate germen, short, two-parted style, and blunt stigmas. PERICARPIUM, none; a single seed lodged in the calix.

The species are,

¹*CHENOPODIUM Bonus-Henricus.*

Good-Henry, All-Good, or Common English Mercury.] Chenopodium with large, triangular, arrow-pointed, entire leaves, from the root; upright, thick, striated stalks, garnished with triangular leaves, and terminated by close spikes of apetalous yellowish-green flowers in June and July, succeeded by ripe seeds in August.

It grows wild by way sides and in bye-lanes, but is sometimes cultivated in gardens as an esculent herb, to use for culinary purposes like spinach.

The three following are hardy ornamental annuals.

²*CHENOPODIUM Scoparia.*

Belvedere, or Annual Mock Cypress.] Chenopodium with upright stalks, closely branching pyramidally from the bottom upward, forming a regular pyramid two or three feet high, fully garnished with very narrow, spear-shaped, plane, entire leaves, and spikes of small greenish flowers.

The merit of this annual is in its beautiful pyramidal growth, resembling a young cypress tree, and is very ornamental; flowers in July, and ripens abundance of seed in autumn.

³*CHENOPODIUM Botrys.*

Botrys, or Multifid-spiked Annual Chenopodium, called Oak of Jerusalem.] Chenopodium with upright branchy stalks near a foot high, garnished with oblong, sinuated, oak shaped, fragrant leaves, and multifid naked spikes.

⁴*CHENOPODIUM Ambrosioides.*

Ambrosia-scented Annual Chenopodium, called Oak of Cappadocia.] Chenopodium with upright stalks two feet high; spear-shaped, indented, odoriferous leaves; and single leafy spikes.

These last two annuals are esteemed principally for the fragrance of their leaves; they flower in July and August, succeeded by ripe seeds in September.

The

The two following are shrubby perennials of the green-house.

CHENOPODIUM Fruticosum.

Shrubby Mexican Chenopodium.] *Chenopodium* with shrubby, durable, branchy stalks, four or five feet high; spear-shaped, indented, fragrant leaves.

CHENOPODIUM Multifidum.

Shrubby Multifid Chenopodium of Bonaria] *Chenopodium* with shrubby durable stalks three or four feet high; multifid, or divided leaves, of many narrow segments.

The flowers of all these species are apetalous, i. e. not adorned with petals, so make no ornamental appearance.

The first species, *Good-Henry*, when intended to cultivate it as an esculent, sow it annually in August, or early in spring, in an open spot, and rake it in, and thin the plants to ten or twelve inches distance.

The *Belvedere*, and the other two annual species, are raised from seed in the full ground in March, sowing it on a bed of rich light earth, and rake it in lightly; and when the plants are two or three inches high, plant them out singly in different parts of the borders; or the seed may be sown half an inch deep, in patches where the plants are to flower, thinning them to a single plant in each place. Some of the *Belvedere* plants may also be potted, in which they have a fine effect, in assemblage with other potted annuals, in adorning any particular compartment.

The scattered or self-sown seeds of the *Belvedere*, in autumn, frequently grow, and the plants rise strong in the spring.

The two shrubby green-house species, are easily propagated by slips or cuttings of their branches, planted in pots of light mould any time from March till June, which, if plunged in a moderate heat, it will greatly forward them.

CHIONANTHUS, Snow-Drop-tree, or Fringe-tree.

This genus consists of one deciduous flowering shrub, adorned with large simple leaves, and clusters of snow-white fringed flowers.

Class and order, *Diandria Monogynia*.

Characters.] *CALIX*, monophyllous, erect, four-parted, and permanent. *COROLLA*, a funnel-shaped petal, divided at top into four long, narrow, erect segments. *STAMINA*, two short filaments inserted in the tube of the corolla, and heart-shaped antheræ. *PISTILLUM*, an oval germen, one style, and blunt trifid stigma. *PERICARPIUM*, an unilocular berry, including one hard seed.

The species is,

CHIONANTHUS Virginica.

Virginia Snow-Drop-tree.] *Chionanthus* with an upright rough stem, dividing into a moderately branchy head eight or ten feet high, garnished with large laurel-shaped leaves, and from every part of the branches long bunches of very white flowers on trifid foot-stalks.

This is a most beautiful shrub for the ornamental plantations of the pleasure-ground, and will prosper in any common soil, though it delights most in that of a somewhat moist loamy nature. Let it however be placed conspicuously, and if so as to have the shelter of other shrubs, there will be the greater chance of its exhibiting a more plentiful bloom.

The propagation of this shrub is by seed, and layers of its young branches; though by this method they emit roots very sparingly, and rarely in less than two years.

The seed is procured from America by the seedsmen, which rarely grows the first year. Let it however, as soon as it arrives, be sown in large pots of fresh loamy earth half an inch deep, and plunge them in a shady border, giving occasional weeding and watering till October; then move them to a frame, or where they can be occasionally sheltered during hard frost in winter; and if in March you plunge them in a hot-bed, it will bring them up freely; which harden gradually to the full air, and give occasional shade from the mid-day sun at their first appearance, and water during summer, and shelter of a frame again from October to April, when the seedlings may be pricked separately in small pots, observing the above care for another year or two, then may transplant them into the full ground.

By layers, chuse the young twigs of last summer, and, as they emit roots reluctantly, it is eligible to give some a slit, others a twist, at the part to be laid in the earth; give plenty of water during summer, and in two years it is probable some will be rooted.

CHRYSANTHEMUM, Corn Marigold, (*Chrysanthemum*).

The plants are mostly herbaceous, and furnish some beautiful flowery annuals and perennials for the pleasure-ground, and some of shrubby growth for the green-house; all of which are upright, very branchy, and from two to four feet high, adorned mostly with finely divided leaves, and compound, radiated, white and yellow flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX, a compound radiated flower, having a hemispherical, imbricated cup. COROLLA, many hermaphrodite and female florets; the former are small, funnel-shaped, five-parted at top, and form the disk; and the females are oblong, ligulated, triparted at the end, and compose the circumference or ray. STAMINA, five short filaments, and tubular antheræ. PISTILLUM, an oval germen, simple style, and two obtuse stigma. PERICARPIUM, none. SEMINA, a naked single seed to each floret.

There are near twenty species; but as the greater part are of no merit in gardening, and some are common weeds of our fields, such as the Common Corn Marigold, and greater Wild Daisy, &c. we shall omit them here, and only introduce those that have merit as garden plants.

The first following is that elegant hardy annual, distinctively called *Chrysanthemum*.

¹CHRYSANthemum *Coronarum*.

Coronated Annual Chrysanthemum.] Chrysanthemum with a single upright stalk from the root, divided into numerous erect branches a yard or more high, garnished with pinnatifid deeply-cut leaves, having the exterior segments broadest, and all the branches and side-shoots crowned by elegant compound flowers, of different colours and properties, in different varieties.

Varieties of this are] Coronated Chrysanthemum with white single and double flowers—cream-coloured single and double flowers—yellow single and double flowers—yellow and white single and double flowers—brimstone-coloured single and double flowers—fistular, or quilled flowers, having all the florets hollow like a quill or pipe—with finely jagged leaves, and flowers of all the above colours and properties.

The flowers of all these varieties, in their natural single state, exhibit a round open disk or middle, composed of numerous, small, tubular florets, and one or two series of long flat florets form the circumference or radius; but in the double flowers, the middle or disk is generally filled with the radius, and some are rendered as completely double as the finest ranunculus, and the impletion is remarkably regular and beautiful; but it is observable, that the first flowers are never so full and double as those which succeed them on the same plant.

All the varieties begin flowering in July; the flowers are exceeding numerous, and ex-

hibit a constant succession of full-bloom till November, and both single and double are succeeded by abundance of seed.

The three next following are hardy perennials.

²CHRYSANthemum *Serotinum*.

American Daisy-flowered Chrysanthemum.]

Chrysanthemum with a very creeping root; upright strong stalks a yard high, divided upward into branches; broad lower leaves sawed on the edges, those above spear-shaped, serrated, and pointed; and each branch crowned by a large white flower.

Varieties.] With double flowers—with deeply jagged leaves.

³CHRYSANthemum *Monspeliense*.

Montpelier Daisy-flowered Chrysanthemum.]

Chrysanthemum with upright branchy stalks three or four feet high; palmated lower leaves of many pennatifid lobes, those above finely divided; and all the branches terminated by large, white, radiated flowers, on long foot-stalks.

⁴CHRYSANthemum *Corymbiferum*.

Corymbus-flowering Chrysanthemum]

Chrysanthemum with upright stalks half a yard high; winged leaves, the lobes cut and serrated; and the stalks terminated by large white flowers in a sort of corymbus.

The flowers of the last three species are shaped like the wild white daisy, but much larger, having large yellow discs, and white radii or rays, appearing in succession from July till September.

The two following are shrubby green-house plants.

⁵CHRYSANthemum *Frutescens*.

Shrubby Canary Chrysanthemum]

Chrysanthemum with a shrubby stalk, divided into a branchy head, two feet high, adorned with narrow, thick, succulent, indented leaves, three-parted at the ends; and small white flowers, growing singly on naked foot-stalks from the axilla of the leaves, appearing at most times of the year.

⁶CHRYSANthemum *Flosculosum*.

Shrubby Floscular Chrysanthemum.]

Chrysanthemum with a shrubby stalk, divided upward into a branchy head two feet high; oblong, indented, close-fitting leaves; and from the axilla of the leaves globular deep yellow flowers, having no rays, but composed wholly of floscular or hollow hermaphrodite florets, appearing from June till November.

The first species, *Chrysanthemum Coronarium*, is a valuable annual for the common borders, and

and other quarters of the pleasure-ground, being grandly ornamental in a great profusion of flowers from July till the approach of winter; and each variety is remarkably prolific in doubles, with this peculiar property, that, although the flowers at their first appearance often exhibit themselves scarcely semi-double, the succeeding ones on the same plants improve more and more double to the very last. This sort is commonly deemed an annual, as, rising from seed in spring, producing flowers and seed the same year, and perishing at the first attack of frost; yet cuttings of its branches potted in autumn, to move to shelter in winter, take root, and continue till next year, and flower earlier by a month than the seedlings. See their *Propagation*.

The second, third, and fourth sorts, are hardy, herbaceous, flowery perennials, proper for the compartments of large pleasure-grounds; they will encrease the variety by an autumnal bloom of two or three months duration, and will grow any where.

The two shrubby sorts require shelter in winter, and, being ornamental, are proper for the green-house collection, so must be always retained in pots of good earth, and managed as other shrubby exotics of the green-house.

Propagation of all the Sorts.

First, of the annual sort, *Chrysanthemum Coronarium*.

This annual and varieties are raised abundantly from seed, either in a hot-bed or warm border, in the spring, for transplanting; also by cuttings and slips of their branches in autumn.

By seed, it may be sown in March or April, and to bring the plants as forward into flower as possible, it should be sown in a moderate hot-bed with other annuals of similar quality, such as the African Marigold, &c. See ANNUAL PLANTS. Or, in default of that convenience, sow it in a warm border under a hand-glass; though, if sown in a warm place in the middle of April, the plants will rise without any covering, but they will be later in flowering than those forwarded as above. In either method sow it moderately thin, either in small drills two inches asunder, covering it the third of an inch deep, or scatter it on the surface, and cover it that depth: the plants will rise in a fortnight or less, giving occasional waterings, and about the middle or latter end of May, or when the plants are

about five or six inches high, take advantage of showery weather, and plant them out singly in the different parts of the borders or fronts of shrubberies, in the places where they are to flower, at six, eight, or ten feet distance, and, if dry weather succeed, give a few waterings the first week or fortnight.

If you are curious to cultivate only the fine doubles, you may, at the time of planting out, set two or three plants together, in patches the above distance, and when they shew flower, to determine the sorts, may clear away the worst, leaving only one of the best doubles in each patch.

When designed to have a shew of the finest doubles in pots, they may be transplanted therein as soon as they are discoverable by their bloom, for they will readily transplant with balls.

By cuttings or slips. This is practised only for the propagation of the fine doubles for an early bloom the following summer, and the best time to perform it is September, or early in October. Cut or slip off a quantity of the robust side-shoots, from three to six inches long, without flowers; divest them of the lower leaves, and plant many of them together in large pots within an inch or two of their tops, and two or three inches apart; give some water, and place them in the shade during the hot weather, and by the end of October they will be rooted, when remove the pots either into a green-house or garden-frame for the winter, but the latter is the most eligible, where they may enjoy the full air in mild weather, and have occasional shelter from frost; and in April transplant them singly into the borders, and some in pots, to move occasionally to ornament any particular compartment.

The plants thus raised will flower a month or six weeks sooner the succeeding summer, than those raised in the spring from seed.

It is however proper always to raise a quantity of seedlings annually, as before directed, so propagating by cuttings from the best doubles of these every autumn, for an early bloom the following summer, because, by continuing to propagate by cuttings always from the same plants, the flowers would degenerate small, less numerous, and at last becomes barren.

To save seed from these varieties, let it always be from the fullest doubles, which, as well as the singles, ripen it abundantly in September.

Propagation of the Perennials.

The three hardy perennial species, which are the second, third, and fourth sorts, may be propagated plentifully, by dividing their roots any time in open weather from October to March. They may likewise be raised by seed sown in a bed of common earth in March, and raked in lightly; the plants will come up in April or May, and in June or July prick them a foot distance in a nursery-bed to remain till October, then transplant them into the borders.

Propagation of the Shrubby Sorts.

The two shrubby sorts are easily propagated by cuttings planted in pots of rich earth any time from April till July, giving occasional shade and water, and by September will be rooted and fit to transplant in separate pots.

CHRYSOCOMA, Goldy-locks, or *Coma Aurca*.

This genus retains herbaceous flowery perennials for the borders, and shrubby ornamental plants for the green-house, all of erect growth, from one to two feet high, ornamented with narrow leaves, and compound floscular flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] **CALIX**, a compound flower in an imbricated cup of many narrow sharp-pointed scales. **COROLLA**, composed of many floscular, hermaphrodite, funnel-shaped florets, five-parted at the brim. **STAMINA**, five filaments, and cylindrical antheræ. **PISTILLUM**, an oblong germen, slender style, and two depressed stigmas. **PERICARPIUM**, none. **SEMINA**, a single seed, crowned with down, to each floret.

The first species is an herbaceous, fibrous-rooted, very flowery perennial.

¹**CHRYSOCOMA** *Linofyris*.

Linofyris, or *German Goldy-locks*.] **Chrysocoma** with upright, round, robust, annual stalks, a foot and half high, garnished with many long, narrow, smooth leaves, and the upper parts dividing into many foot-stalks, each supporting a head of bright yellow flowers, the whole forming a sort of umbel, appearing in July, and ripen seeds in autumn.

The two following are dwarf shrubs of the green-house.

²**CHRYSOCOMA**, *Coma Aurea*.

Shrubby Coma Aurea, or *Greater African Goldy-locks*.] **Chrysocoma** with a shrubby stem,

divided into a slender branchy head two feet high, garnished with numerous, narrow, running leaves, each having a leafy appendage detached from the back part along the stalk, and pale yellow flowers on slender naked foot-stalks from the ends of the branches, all summer and autumn.

³**CHRYSOCOMA** *Cernua*.

Shrubby Nodding Goldy-locks.] **Chrysocoma** with a shrubby stalk, divided into a branchy head, a foot and half high, garnished with short, narrow, hairy leaves, and pale yellow flowers, nodding on one side, appearing from the beginning of summer till autumn.

The first species, *German Goldy-locks*, flowers very ornamentally about six weeks, and succeeds in any of the compartments of the pleasure-ground; its propagation is by dividing the roots any time in open weather from September till March, or it may be raised from seed in a bed of light earth in March or April.

The two shrubby sorts must be kept in pots, and placed in a green-house in winter.

They are easily propagated by cuttings, in pots of light rich earth in spring or summer, which, if plunged in a little heat, or closely covered with a hand-glass about a month, they will readily grow.

CICHORIUM, Succory, or Endive, (*Endivia*.)

This genus furnishes but one useful species, an herbaceous esculent of the kitchen-garden, valuable both as a salad and a culinary herb, of which there are three eminent varieties.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] **CALIX**, a compound flower, having a calyculated, imbricated, permanent, general cup. **COROLLA**, many hermaphrodite, plane, tongue-shaped, five-parted florets, placed in a circle. **STAMINA**, five filaments, and cylindric, pentagonous antheræ. **PISTILLUM**, an oblong germen, slender style, and two revolute stigma. **PERICARPIUM**, none. **SEMINA**, a single seed to each floret, lodged in the calix.

There are three species in the whole; the Wild Succory of the fields—the Prickly Succory of Sicily—and the cultivated Succory or Endive of our gardens; but the two former have no merit as garden-plants.

The Succory of our gardens is,

CICHORIUM *Endivia*.

Endive, or *Garden Succory*.] **Cichorium** with a spindle-shaped fibrey root, crowned by a compact cluster of numerous, oblong, spreading

ing leaves, close to the ground, from about six to ten or twelve inches long, near half as broad, in some sorts fringed and curled, others plane and entire, and in the centre an upright branchy seed-stalk a yard high, garnished with small leaves, and solitary blue flowers, succeeded by plenty of seed.

Varieties are,

Green Curled Endive—hath numerous, green, finely fringed, and curled leaves, forming a circular cluster close to the ground twelve or fifteen inches diameter; the centre leaves many, very closely placed, and grow to a large, compact, finely-blanced, white heart. This is considerably the finest variety of Endive for general culture, both for fallads and culinary purposes, and is the hardiest to stand the winter. But the great article is, to have the true sort; for some have long, irregular, thinly-placed leaves, very little curled, and the heart open and loose; therefore, in saving seed, be particular in marking the fullest-leaved, most curly, regular, bushy plants, that bottom well, and have the heart perfectly full, close, and white.

White Curled Endive—hath numerous, white, very fringy, curled leaves, in a circular cluster close to the ground, ten or twelve inches diameter, very full and close in the heart.

Broad-leaved Batavia Endive—hath long, broad, plane, entire leaves, of a whitish-green colour, thick and crisp like coss-lettuce; but is more proper for culinary uses than fallads, nor is it so hardy to stand the winter as the former varieties; so should be cultivated only for autumn service, i. e. use in August, September, October, and November.

All the varieties may be considered both as annuals and biennials. Considered as annuals, that if sown early in spring, or even any time before the beginning of June, the plants very commonly fly up to seed the same summer, in their minor, or half-grown state, and perish in autumn. As biennials, that if sown in June or July, the plants acquire perfection in autumn, continue till the spring following, then shoot up stalks for flower and seed, and soon after perish; so, at most, they are never more than biennial.

It is the inner leaves of all the varieties that are the useful parts, which, when blanched white, to render them crisp and tender, and to reduce them from a naturally strong, to an agreeable bitter taste, are then fit for use.

They are valued chiefly as principal furniture for autumn and winter fallads, and for some culinary uses; and their principal season of perfection is, from the latter end of August until Christmas, or longer, according to the temperature of the season; though the curled kinds generally resists the frost of our ordinary winters, and remain in tolerable perfection till March or April.

Propagation and Culture.

The propagation of each variety is by seed annually in an open spot of ground, from which the plants are to be transplanted a foot distance, in open beds or borders, to remain to grow to full size, when their leaves are to be tied together, to promote their blanching white.

The principal season for sowing these seeds is from the beginning of June to the end of July; and to have a regular supply of plants, it is proper to perform three different sowings at about three weeks or a month's interval, observing, that if sown before the first week in June, the plants are apt to run to seed the same year without acquiring perfection; and, if sown later than July, they have not time enough to grow to any tolerable size before the approach of winter: however, where the plants are required as early as possible, you may perform an earlier sowing, but the earliest should never be before the middle of May, and even that sowing is apt to fly up soon to seed, so must never depend on this sowing for a main crop; therefore, for the general autumn, winter, and spring crops, I advise the first sowing to be in the first week in June, the next in the last week in the same month, and the third and last about the fifteenth or twentieth of July; and each of these sowings will afford two or three different drawings or transplantings; for it is eligible to make five or six plantations at least, at different intervals, whereby a regular succession of good Endive will be obtained from August until April.

All the sowings should be performed in an open exposure, and the richer the ground the better, which, after being dug, form into a bed or beds four feet wide; directly sow the seed by broad-cast moderately thin, and tread and rake it in with a large rake.

The plants will come up in ten or twelve days, when, if the weather is dry, give occasional waterings; keep them clean from weeds, and where they rise in clusters, thin them

them to two inches distance, that they may not draw each other weak, and, when about a month old, transplant the largest in the following manner.

When the plants of each sowing are from three to four or five inches high, they are then of a proper size for planting out, which should be at once in the place where they are finally to remain; they should be allowed a spot of as rich ground as you can afford, and an open exposure is most eligible for the main crops that are planted out in June, July, and August; but for those intended principally for spring service, which are planted out in September, should be set near the shelter of a South wall or hedge. At each time of planting chuse moist weather, if possible, and let the ground be then neatly dug one spade deep; divide it into four feet wide beds, and rake the surface smooth; then draw out a quantity of the stoutest plants from the seed-bed, with their roots as entire as you can, and if the plants have run up with long leaves, trim their straggling tops all of equal length, then plant them by line and dibble four rows in each bed, and a foot distance in the rows; and that the plants may have the more room to spread, set them in the quincunx order, (see QUINCUNX) finishing the work with a good watering, unless the weather is very showery, when you may spare yourself that trouble, though, at any rate, a little water at planting settles the earth close to their roots, and is of much advantage; and if the weather is dry, the waterings should be repeated every other day for a week, or till the plants have taken root.

In this manner it is adviseable to make a fresh plantation every fortnight, from June to the middle of September, by which practice you will obtain a regular succession of Endive in due perfection from August till the following spring, proper either for family service, or for market.

When there is a necessity of planting any out in very dry weather, it is proper to draw flat shallow drills a foot distance; so set the plants therein a foot asunder, that when water is given, the drills will detain it about the plants, and the earth will retain a moistness longer than the level ground.

As to the general culture of the different crops, keep each plantation clean from weeds, by hoeing between the plants carefully in dry weather; and when the plants are nearly full grown, a quantity of the largest should

have their leaves tied up for blanching, which is to be repeated in successive order, and the following is the directions.

Method of Blanching the Plants.

The great excellence in good Endive is to have the inner parts of the plants finely whitened or blanched, without which they would be tough and disagreeably bitter; the plants of themselves naturally incline to whiteness in the hearts, but this may be greatly promoted and improved by art, when the plants are arrived at full growth. Different methods are practised, such as tying the leaves of each plant up close together; taking up the plants, and replanting them directly almost to their tops in ridges of dry earth; laying boards or tiles flat-ways on the plants; but this latter is the most unnatural and ineffectual of all the methods; and the best of all is the tying up the leaves, which in a fortnight will be blanched. The proper period to begin this work is, when the plants are nearly full grown; that is, when they are so much advanced, that the leaves of the different plants interfere, and their hearts are full and bushy; but they are not all to be tied up at once, only a due supply of the largest and forwardest plants once every ten or twelve days, according to the demand either for private use or market. Dry weather, if possible, ought to be chosen for this work, and when the plants themselves are also dry, then, having some strong bass strings, or osier twigs, gather all the leaves of each plant up regularly, divesting them of damaged ones, and with these materials tie them close together a little above the middle, or within about three inches of the top, being careful not to bind them too straight.

In fifteen or eighteen days some of the forwardest plants of each tying will be tolerably well blanched, but in about three weeks they will be in excellent order.

To blanch them in ridges of earth. This is sometimes practised in winter, when there is danger of severe frost setting in; for by burying the plants almost to their tops, they are more out of the power of frost. In November or December, or when you apprehend hard weather is approaching, let a warm-lying piece of light dry ground be trenched up in one or more sharp ridges two or three feet wide at bottom, and near as much in height, and side-ways to the sun, making the sides as steep as possible, that wet may run quickly

quickly off; then, in a dry day, take up a quantity of your full-grown plants, with their roots entire, divesting them of damaged leaves, and then gathering each plant close in your hand, place them horizontally in the sunny side of the ridge of earth almost to their tops, and about six or eight inches each way distant, which is room enough, as it is only just to blanch them; here they will take root and blanch effectually, observing, that when severe frosty weather prevails, it would be of much advantage to cover the ridge with dry long litter, to secure the plants, and prevent the earth from being frozen hard, that they may be readily taken up when wanted.

In very severe weather, it would also be of much advantage to bestow covering on some of the best plants in the full ground; and where there is only a few for family use, it may be easily effected either by mats or dry long litter, being careful to remove the covering as soon as the weather alters.

Saving the Seed.

Particular attention is necessary in saving Endive-seed, to mark for that purpose some of the very best sorts of each variety, for the plants are very subject to degeneracy.

Therefore, in October or November, place some sticks as marks to some of the most stocky full plants, which may either remain, or in March be transplanted into a sheltered sunny situation, in rows two feet distance, and eighteen inches asunder in the lines; or if planted in a single row against a south wall, pale, or hedge, it would be convenient for supporting their seed-stems. They will shoot up their stems in April or May, which early in June will require support, either of a stout stake to each plant, or, if situated against a wall, &c the stems may be fastened thereto by a line of packthread; the seed will ripen in July and August, having attention to cut off the branches from time to time as the seed acquires maturity, which, according as it is properly dried in the sun, beat out on cloths, and put it up for use in bags or boxes.

CIRRHUS, a Clasper or Tendril; that fine spiral string issuing from the branches, foot-stalks, and leaves, of many sorts of trailing and climbing plants, by which they fasten themselves to other bodies for support.

A Clasper is one of the seven species of *Fulcræ*, or props or supports of plants. See **FULCRÆ**.

Claspers are of singular use to most of the trailing and climbing tribe, in assisting them to climb and support themselves, as they mostly have long, slender, fragile stalks and branches, which would trail on the ground, and be liable to be displaced, and frequent breakings, unless by means of their tendrils, which either twine round any thing in their neighbourhood; as, for instance, those of peas twine round sticks or bushes, and thereby mount their stalks and branches seven feet high; and those also of the vine and passion-flower, and of many others, twine round their own, or neighbouring branches, or any other contiguous support; and some climbers emit Claspers, which plant themselves like roots in the adjacent walls, or the bark of neighbouring trees, as exemplified in ivy, the *Bignonia Radicans*, the *Solanum Dulcamara*, and many other sorts; their stalks thereby mounting thirty or forty feet high. See **CLIMBER**.

As to the situation of Claspers on the respective plants, they sometimes are placed opposite to the leaves, as in the vine; sometimes at the side of the foot-stalk of the leaf, as in the passion-flower; and sometimes proceed from the leaves themselves, as in the pea; and are either simple, or of one string, as in most *Cirrhous* plants; or compound, i. e. of two or more, as in *Lathyrus Latifolius*, broad-leaved or common everlasting pea.

CISTUS, Rock-Rose, (*Cistus*).

This genus furnishes beautiful shrubby evergreens for the pleasure ground and greenhouse, adorned with oblong, spear-shaped leaves, and numerous quinquepetalous white and purple flowers.

Class and order, *Polyandria Monogynia*.

Characters.] **CALIX**, five roundish concave leaves. **COROLLA**, five roundish, large, plane, patent petals. **STAMINA**, numerous capillary filaments, and roundish antheræ. **PISTILLUM**, a roundish germen, single style, and plane orbicular stigma. **PERICARPIUM**, an oval, covered capsule, and numerous, small, roundish seeds.

There are numerous species of *Cistus*, the greater part of which are of the shrub kind, and there are some of herbaceous growth; but those that merit notice in gardening are mostly shrubby evergreens, very floriferous and ornamental.

The species of our gardens are,

Cistus Populifolius.

Poplar-leaved Cistus.] *Cistus* with a shrubby stem,

stem, branching each way five or six feet high, garnished with large, heart-shaped, pointed, smooth leaves, having foot-stalks; and at the sides and ends of the branches numerous large white flowers.

²*CISTUS Ladaniferus.*

Ladanum-bearing, or Spanish Gum Cistus.] Cistus with a shrubby strong stem, branching from the bottom upward, forming a bushy head five or six feet high, adorned with spear-shaped leaves, smooth and green on the upper side, whitish and veined below, standing on short foot-stalks joining at their base round the branch like a sheath; and numerous large purplish flowers at the sides and ends of the branches.

Varieties.] Willow-leaved Ladaniferous Cistus—having narrow pear-shaped leaves, and large white flowers, having a purple spot at the base of each petal—and with entire white flowers.

³*CISTUS Albidus.*

White Downy-leaved Cistus.] Cistus with a shrubby stem, branching erectly from the bottom five or six feet high, having woolly branches, garnished with oval-spear-shaped, trinervous, white, downy, close-fitting leaves; and all the branches terminated by large bright purple flowers.

⁴*CISTUS Creticum.*

Cretan Ladaniferous Cistus.] Cistus with a shrubby stem, branching laterally three or four feet high; oval-spatulated, enervous, rough leaves, on short foot-stalks; and deep purple flowers, on footstalks at the ends of the branches.

⁵*CISTUS Monspeliensis.*

Montpelier Gum-Cistus.] Cistus with a shrubby stem, branching laterally from the bottom upward, three or four feet high; spear-shaped, trinervous, hairy, close-fitting, dark-green leaves; and from the ends of the branches, long naked foot-stalks, sustaining many large white flowers.

⁶*CISTUS Pilosus.*

Hairy Round-leaved Cistus.] Cistus with a shrubby, strong, rough stem, branching to a large bushy head, a yard or four feet high, garnished with oval-roundish hairy leaves, growing opposite on short foot-stalks; and many large purple flowers from the sides and ends of the branches.

⁷*CISTUS Incanus.*

Hoary-leaved Cistus.] Cistus with a shrubby stem, branching to a large bushy, head three or four feet high; spatulate-shaped, hoary, rough, close-fitting leaves, the lower ones

oval and united at their base, the upper ones spear-shaped and distinct; and all the branches and shoots terminated by large purple flowers.

Varieties.] Long-leaved Hoary Cistus—Roundish-leaved Hoary Cistus—Large Hoary-leaved Cistus.

⁸*CISTUS Crispus.*

Waved Curled-leaved Cistus.] Cistus with a shrubby stem, diffusing horizontal branches, forming a spreading head a yard or more high; spear-shaped, waved, bending, hairy leaves, in pairs opposite; and from the axillas of the leaves, many white flowers on naked foot-stalks.

⁹*CISTUS Salvisolius.*

Sage-leaved Cistus.] Cistus with a shrubby, slender, smooth stem, a yard high, branching horizontally and spreading, garnished with small, oval, hairy, petiolated leaves; and from their axillas, white flowers on long naked foot-stalks.

¹⁰*CISTUS Laurifolius.*

Bay-leaved Gum-Cistus.] Cistus with a shrubby strong stem, branching erectly, forming a head five or six feet high; oblong oval, trinervous, petiolated leaves, smooth and green above, their foot-stalks joined at the base; and from the sides and ends of the branches, large white flowers on branching foot-stalks.

¹¹*CISTUS Halimifolius.*

Sea-Purflane-leaved Cistus.] Cistus with a shrubby stem, branching erectly from the bottom upward, forming a bushy head four feet high, adorned with oblong-oval, very white, hoary leaves, in pairs opposite; and at the sides and ends of the branches, very long, branching, naked foot-stalks, supporting large, bright, yellow flowers.

Varieties.] Broad-leaved Halimifolius Cistus—Narrow-leaved Halimifolius Cistus.

The flowers of all these species are composed each of five large, round, spreading petals, see the *Characters*; and are extremely numerous on the plants, appearing principally in May, June, and July; and many of the sorts afford plenty of ripe seeds.

The leaves of these shrubs exhibit great variety in different species, being of very different shapes, sizes, and of many different shades of green and white, and which, in most of the species, are covered with a clammy or gummy substance, of a strong balsamic scent, of which is prepared the ladanum of the shops; hence several of the species are titled Ladaniferous, or Gum-bearing Cistus, which they

they impart more abundantly in the summer months, and is collected for use in the countries where the shrubs naturally grow.

They are natives principally of the southern parts of Europe, but succeed here in the open air the year round.

All the species are beautiful evergreen shrubs, generally very branchy quite from the bottom, forming diffused heads, and are all very ornamental in gardens, not only as evergreens, effecting a fine variety at all seasons, with their leaves of different figures, sizes, and shades of green and white, but also as first-rate flowering shrubs, being very profuse in most elegant flowers, which, though of only one day's duration, there is a daily succession of great numbers of new ones, continued a month or six weeks on the same plant; and when there are different species, they will exhibit a constant bloom near three months, and all the sorts begin flowering when little more than a foot high.

They are all hardy enough to prosper in the full ground in any dry soil, and if they have a sheltered situation it will be an advantage, as, in open exposures, they are rather subject to injury from very severe frost; for which reason, where there is green-house room, a plant or two of each sort may also be potted to have shelter in winter, by way of reserve, especially while young.

The more tender sorts are the *Cistus Laurifolius*, and *Halimifolius*.

Their situation in shrubbery works should be towards the front of the clumps and other compartments, in assemblage with the choicest shrubs of similar growth, dispersing them so as to effect variety, and to have shelter of the other plants; but by no means crowd them.

Let all the sorts assume their own natural growth, that is, never to shear or trim them close, but only just shorten or retrench with a knife any particular rambling branch.

Propagation.

All the sorts of *Cistus* are raised by seeds and cuttings, either in common earth, or in a hot bed.

The seeds produce the handsomest plants, and the time for sowing is March. These seeds may either be sown in a warm border near half an inch deep, and the plants will come up in six weeks; or, to bring them more forward, the seed may be sown in pots, and plunged in a moderate hot-bed, and the plants will appear in less than a month, when

they must be afforded the full air in mild weather; and frequent waterings is also necessary to the plants raised in either method, as well as occasional shade from the scorching sun while young. The plants will grow near a foot high the same year; but when they are an inch or two high, some may be pricked out to thin them, planting some separately in small pots, others in a rich border, giving occasional shade and water during summer, and in October move the potted plants to a frame to have shelter from frost; all those in the full ground should also be shielded in frosty weather with mats. In spring, those left in the seed-bed should be planted out, and the potted plants shifted into larger pots, in which they may be continued, to have shelter another winter; and in spring following transplant most of them into the nursery, or where they are always to remain.

By cuttings: their propagation this way may be performed any time from May till August. Chuse cuttings five or six inches long, and plant them in a bed of rich earth, giving occasional shade and water; they will be rooted, and fit to transplant into separate pots in eight or ten weeks, managing them as the seedlings.

If a quantity of cuttings are planted in pots in spring, and plunged in heat, it will bring them much forwarder.

CITHAREXYLON, Fiddle-wood, or Fidelle-wood.

It furnishes two beautiful evergreen shrubs for the stove, adorned with large oblong leaves, and bunches of funnel-shaped, monopetalous, white flowers.

Class and order, *Didynamia Angiospermia*.

Characters.] **CALIX**, monophyllous, and indented into five parts. **COROLLA**, one funnel-shaped petal, five-parted and spreading at top. **STAMINA**, two long and two short filaments, and didymous antheræ. **PISTILLUM**, a roundish germen, slender style, and headed stigma. **PERICARPIUM**, a roundish unilocular berry, and two seeds.

The species are,

¹**CITHAREXYLON Cinereum.**

Cinereous Citharexylon.] Citharexylon with an upright robust stem, taper branches, and cinereous bark; oblong-oval firm leaves, placed opposite; and at the sides and ends of the branches loose spikes of white flowers.

²**CITHAREXYLON Caudatum.**

Caudated Citharexylon] Citharexylon with an upright robust stem, divided into many

taper branches; oboval opposite leaves; and long spikes of white flowers at the ends of the branches.

They grow to large trees in America, but appear like shrubs in this country, where they must be always retained in pots, and continued in the stove, except about two months in the heat of summer.

Both the species are propagated by seed procured from America, sowing it half an inch deep in pots of rich earth, and plunge them in a bark-bed.

They may also be propagated by cuttings planted in spring in pots of rich earth, and plunged in the bark-bed.

CITRUS, the Citron-tree, including the *Limon* or Lemon-tree, and *Aurantium*, the Orange-tree.

Former authors on gardening and botany considered the Citron, Lemon, and Orange, as three distinct genera, and treated of them accordingly; but their generical characters being the same, Linnæus joins them all as species and varieties of the genus *Citrus*.

They are all most beautiful evergreens of the tree kind, natives of distant warm climates, so are retained here as green-house plants.

Class and order, *Polyadelphia Icosandria*.

Characters.] CALIX is monophyllous and indented in five parts. COROLLA, five oblong, plane, spreading petals. STAMINA, twenty filaments, united below into several bodies, and oblong antheræ. PISTILLUM, a roundish germen, cylindric style, and globular stigma. PERICARPIUM, a large, baccaceous, oval, fleshy-rinded fruit, full of succulent pulp, and divided internally into nine cells, each containing two oval hard seeds or kernels.

There are but three species, each of which admits of many varieties in respect to the properties of their respective fruit, though, according to Linnæus, the Lemon is only a variety of the Citron; there is indeed but little difference in their general habit, only that the Citron is rather the strongest shooter, the leaves and fruit larger; and the leaves of both these sorts are large and thick, and having linear foot-stalks, are distinguishable from the Orange, whose leaves are rather smaller, and of thinner substance, and have winged foot-stalks, (*petiolus alata*) i. e. a sort of leafy appendage at the base of each leaf.

The species are,

¹CITRUS *Medica*.

The Citron-tree.] Citrus with an upright

smooth trunk, divided at top into a branchy, strong-shooting, full head, from about five to fifteen feet high, adorned with large, oval-spear-shaped, thick leaves, having linear foot-stalks, and numerous flowers from the sides of the branches, succeeded by very large, oblong oval, pointed, rough-rinded fruit.

There are many varieties; the fruit is held to be a sovereign remedy against poison, and is an excellent sweetmeat, for which it is principally esteemed, being rarely eaten raw.

The Varieties of note are] Citron-tree with four fruit—with sweet fruit—with warted fruit—with long fruit—with recurved fruit—with bloated leaves.

²CITRUS *Limon*.

The Lemon tree.] Citrus with an upright smooth trunk, divided upward into a branchy regular head, from five to twelve or fifteen feet high; large, oval, spear-shaped, pointed, slightly-sawed leaves, on linear foot-stalks; and many flowers from the sides of the branches, succeeded by large oval fruit, prominent at the top.

Varieties of note are] Lemon-tree with four fruit—with sweetish fruit—with very large fruit, called Imperial Lemon—with pear-shaped fruit—with furrowed fruit—with clustered fruit—with childing fruit—with whitish fruit—with tricolor-striped fruit—with gold-striped leaves—with silver-striped leaves—with double flowers.

The Lima, or Small American Lemon, called Lime—the tree having somewhat spinous branches, oval entire leaves, and very small four fruit—and with sweet fruit.

³CITRUS *Aurantium*.

Aurantium, or Orange-tree.] Citrus with an upright trunk, dividing upward into a branchy regular head, from five to ten or twelve feet high; oval, spear-shaped, entire leaves, having winged foot-stalks, and numerous white flowers at the sides of the branches, succeeded by globular fruit, compressed at both ends.

Varieties of most note are,

Seville Orange—A large, rough-rinded, four fruit, of excellent quality for æconomical uses. The tree is a handsome grower, and rather the hardiest of all the Orange tribe, as in this country it shoots freely, produces large and beautiful leaves, and flowers stronger and more abundantly, and generally bears a greater quantity of fruit, than any other sort, and arrives to greater perfection; so these trees should be the most cultivated.

China Orange—The tree has moderate sized leaves,

leaves, and a smooth, thin-rinded, sweet fruit, of which are several varieties in warm countries, where they grow in the open ground.

Great Shaddock-Orange, or Pumplemoes—The tree a large grower and strong shooter, with large, thick, somewhat serrated leaves, and very large fruit, having a reddish pulp; derives the term *Shaddock* from one of that name, who first brought it from the East-Indies.

Horned Orange—A common-sized tree, producing fruit which divide, and the rind runs out into divisions like horns.

Hermaphrodite Orange—A common sized tree, producing fruit partly like an Orange, and partly Citron-shaped.

Willow-leaved Orange-tree—having narrow, spear-shaped leaves—Striped Willow-leaved Orange.

Dwarf Orange-tree, or Nutmeg-Orange—having a low stem, and small bushy head, growing two or three feet high; small oval leaves in clusters; and numerous flowers in clusters, covering the branches, succeeded by very small fruit.

Other varieties are—Silver striped-leaved Orange-Tree—with gold-striped leaves—with curled leaves—with double flowers.

Of each of the above three species, there are many more less material varieties than are here noticed, in the countries where they grow in the open ground; and the varieties, like our apples and pears, may be multiplied by seed without end, but, like other fruit so raised, it is probable there may not be one in a hundred worth notice; so that the approved sorts can only be continued with certainty by budding.

The flowers of all the species and varieties are formed each of five spreading petals, appearing here principally in May or June, and the fruit continue setting in June and July, and ripen the year following.

All the sorts are elegant evergreens of the tree kind, obtaining in England from about five to eight or ten feet stature, forming full and handsome heads, closely garnished with beautiful large leaves the year round, and a profusion of sweet flowers, in spring and early in summer, which, even in this country, are often succeeded by abundance of fruit, sometimes arriving to tolerable perfection; but the chief merit of these trees in England is for ornament, which consists not only in their beautiful foliage, but also in the flowers and fruit, and have this peculiar merit, as to exhibit blossom, green fruit in different stages

of growth, and full-grown ripe yellow fruit, all at the same time, which, together with their large shining-green leaves, effects one of the most beautiful contrasts of our gardens, which renders all the sorts very desirable furniture for the green-house collection; but the Oranges and Lemons are rather the hardiest, and generally more fruitful here in England than the Citron, and the Seville-Orange most of all, which is the only sort of Orange to be depended on for any considerable quantity of flowers and fruit; the tree being hardiest, retains its fruit in winter better than most of the other varieties.

These trees are all natives originally of India, but have been long retained in our gardens as green-house plants; and in the southern parts of Europe, as Portugal, Spain, and Italy, they grow in the open ground like our apple and pear-trees, and from which countries vast quantities of the fruit are imported hither annually; but here in England the trees must always be continued in pots or tubs, to be housed in winter.

They all succeed in the open air from the beginning of June until the middle or latter-end of October, and the rest of the year must have the shelter of a green-house, and they prosper in any good garden-mould. See their *General Culture*.

Trees of all these sorts are retained in most of the nurseries for sale, where such persons as are in haste to have a collection may be furnished; the prices from five shillings to as many guineas, according to the sorts, sizes, and properties.

As to the method of raising and management of all the sorts, see the following different articles of their *Propagation*, and that of their *General Culture*.

Their Propagation by Seed for Varieties, and to raise Stocks to bud upon, &c.

All the varieties of this genus were originally obtained from seed; but the only certain method to continue the respective approved varieties is by budding or inarching them on stocks of their own kind, raised from seed to a proper size. See their *Propagation by Budding, &c.*

By seeds, i. e. the kernels of the fruit: this method of raising these trees is rarely practised in England, except for stocks, on which to bud the different kinds; for although raising the trees entirely from seed, without budding, is the way to gain new varieties, as observed

observed of peaches and other fruits, yet out of numbers so raised, it is probable not a tree of them may produce fruit that possess any good property, but what will be small, crab-like, and intolerably sour and harsh; but when any new valuable variety is by this means accidentally obtained, it is continued and multiplied by budding it upon stocks, raised from the kernels of any of the sorts of *Citrus*, for they all take upon one another, see their *Propagation by Budding*; and by which practice all the above-described varieties are annually increased in our gardens. As the method therefore of raising them entirely from seeds, except for stocks, is both tedious and uncertain; that is, it is tedious, because they are often many years before they arrive to a bearing state, and uncertain, as, that after all the trouble, they perhaps are neither beautiful in their foliage, flowers, nor fruit, compared with those which are budded with the known and approved kinds; so that in this country it is scarce worth practising, unless a few merely for curiosity.

The raising them, however, from the kernel, either to form trees for new varieties, or for stocks to bud upon, is, in this country, performed the most effectually and expeditiously by the aid of a hot-bed, and by which means stocks may be obtained, of due size for budding, in two years; the following is the method of raising them.

Early in spring procure some kernels, which may be had plentifully from rotten fruits, or others that are perfectly ripened, observing, that for stocks, the Citron, Lemon, and Seville-Orange, as being the freest shooters, are to be preferred, though the Citron is the strongest shooter of the three: sow the kernels in March, in pots of rich light earth half an inch deep, and plunge them in a hot-bed, under frame and glasses, of dung or tan, but the latter is preferable, giving air, and frequent sprinklings of water. In two or three weeks the plants will come up, being careful to give air and water, and in six weeks, or two months more, they will be advanced four or five inches, or more, in height; observing, in the middle or latter end of June, to harden them to the full air, in which let them remain till October, then move them into the green-house, to stand till spring, when, in March or April, proceed to plant them singly in small pots (forty-eights), being careful to shake them out of the seed-pot with their roots entire, and having half filled the other

pots with light, rich, loamy compost, place one plant in each pot, filling it up over the roots with the same sort of earth, and let them be directly watered, repeating it occasionally till fresh rooted; afterwards treat them as other woody exotics of the green-house, and in a year or two, the largest of those designed for stocks will be fit to bud.

But, to have stocks as forward and fine as possible for budding, I would advise, where convenient, that, as soon as they are potted out as above, to plunge them directly in a hot-bed, under a frame and glasses, about three or four months, which will draw them up in height with handsome stems.

A bark-bed would be the most eligible, made either in a glass-pit, or to be covered with a deep frame and lights; so plunging the pots to their rims in the bed, giving occasional shade in the middle of hot sunny days, and fresh air daily, by tilting one end of the lights, more or less, as you shall judge expedient: likewise refresh them frequently with water, and by the middle or end of July the plants will be advanced fifteen or eighteen inches, or near two feet high, observing then to harden them by degrees to the full air for the remainder of the summer; and, by being thus forwarded, those designed for stocks will be in excellent order for budding the year following. See their *Propagation by Budding*.

But these seedlings may still be more forwarded, and a year or two's growth may be gained by forcing them, as above, the first season. This is effected by pricking out the seedlings the first year they come up, when two or three inches high, in small pots, as above, to be plunged either in a bark-bed, or even in a dung hot-bed, covered with old tan eight or ten inches deep for the reception of the pots, made in a bark-pit, or, at least, under some deep frame and glass, as before directed; the plants are then to be potted singly, according to the former directions, and plunged in the hot-bed, indulging them, as before advised, with occasional shade, fresh air, and water; and by the middle or end of July, they will have advanced to twelve or fifteen inches, or, perhaps, to a foot and half, or near two feet in height; they must then be gradually hardened to the full air, by raising the lights more and more every day, leaving them also up on nights, and at last take them quite off in a cloudy calm day; so let the plants remain fully exposed till October, then move them into the green-house for the winter, and

and many of them will be in due order to receive the buds next August; and the following is the method.

Propagation by Budding.

The operation of budding all the sorts of *Citrus* is performed in August upon stocks of their own kinds, for all the species and varieties of this genus take freely upon one another, and the budding or inoculation is performed in the common way. See INOCULATION.

But, as already noticed, the Citron, Lemon, and Seville-Orange, being the freest shooters, are generally preferred for stocks; and those of all the sorts are raised from the kernel, as above directed in the *Propagation by Seed*, which, when from about fifteen to eighteen inches, or two feet high, and about as big as a middling goose-quill, or a little more or less, are of due size for budding.

As to the buds for budding them, observe to procure cuttings only from bearing free-shooting trees, of the sorts you would encrease; young shoots, that are round and plump, must be chosen, and from these take the buds in the usual manner, being careful to insert them in a smooth part of the stock, at about six to ten or fifteen inches from the bottom, one bud in each stock, tying them properly with a ligature of bafs. See INOCULATION.

As soon as the budding is finished, it is proper to place the plants in their pots in the green-house, or in a glass-case, &c. to defend the buds from wet and drying winds, turning the budded part from the sun; or, where there is the convenience of a spare bark-pit, where the heat of the bark is almost exhausted, may plunge the pots therein two or three weeks, and it will more effectually promote the union of the buds; observing, in either department, to admit air freely, by opening the front glasses, allowing also a slight shade of mats in the middle of scorching sunny days, and supply the pots with water every day or two during the hot weather; in three or four weeks the buds will be united with the stocks, when it is proper to loosen the bandage of each bud, that they may have room to swell; observing, however, that the buds will all remain dormant till spring.

After this there is nothing more required this year but due waterings, only observing, that in case of great rains, it will be proper to retain the plants in the green-house for the

remainder of the summer, and until next spring.

In March following, the heads of all the stocks must be cut off slanting close behind the insertion of the bud; after this operation the buds will soon begin to spring, and produce each one shoot, which probably will obtain from about five or six, to eight or ten inches in length the same year; but it is proper to observe, that if they could have the aid of a bark-bed, there will be a chance of having the buds shoot a foot and half, or more, by the end of summer; therefore, where there is the convenience of a bark-pit, or glass-case, or any deep frame, that can be placed on a bark bed, &c. I should advise by all means to make use of such conveniencies for forwarding the first shoot of the buds; so that as soon as the stocks are headed, as above directed, plunge the pots in the hot-bed, and let them enjoy the benefit of air and water, in proportion to the temperature of the bed and weather; likewise occasional shade when the sun is very powerful: here they may be continued, with the above care, till the end of July, when some of the strongest shooters will be advanced near two feet high; and it is then proper to begin to inure them by degrees to the full air, to harden them against winter, that they may be able to live during that season in the green-house, to which they must be removed in October.

As to their culture, in respect to training, you may train each with a stem to what moderate height you think proper, though, when they have formed stems two or three feet high, I would suffer them to branch out towards the top, to form a head, which should be permitted to retain their natural growth, unless you shall see necessary to shorten any particular shoots, that they may throw out laterals, to form a fuller or more regular head; likewise to retrench or shorten any very irregular or rambling branch.

For their further management, see their *General Culture*.

Propagation by Inarching.

This method of propagating *Citrus*-trees was more in practice formerly than since the art of budding them has been so improved, as to form much handsomer trees. See INARCHING.

When it is however designed to propagate by this method any of the sorts of *Citrus*, stocks must be raised from seed, as before directed,

directed, which, when of due size, are to be placed in their pots, upon a sort of stage, or some erection convenient to the head of the trees you intend to inarch from, observing to fix upon some convenient young shoots, nearly the size of the stocks, for the purpose of inarching; these are to be inarched in the stocks, as they grow on the trees, in April or May, one in each stock, and by the end of August following they will be united to the stock, and may be separated from the parent tree.

But this method of propagating these trees, is rather practised by way of curiosity, to raise a few trees to a bearing state in haste, because, by inarching a young bearing branch, furnished with fruit, into any of their own stocks, in April or May, it will frequently be united by the following August, and the branch so inarched may be separated from its parent plant, and, being firmly attached to the stock, it then commences a new tree, bearing fruit, raised in the short space of four or five months.

By the same rule you may inarch an Orange into the branch of a Citron or Lemon, or all three upon the same tree, for the sake of variety.

But trees raised by this method never grow so large nor handsome as those raised by budding.

Of managing the trained Trees brought from abroad.

If any one is anxious to have a collection of large trained trees of any of the sorts of *Citrus* as soon and as cheap as possible, the only way is, to have recourse to those imported from Italy or Portugal, &c. great quantities of trained trees of all the sorts being imported hither from those countries every spring for sale; they come over in chests, without any earth to their roots, having their roots and heads a little trimmed; they are in size commonly from about one inch to two or three diameter in the stem; the stem from two to four or five feet high; and by aid of a bark-bed they readily take root and grow freely, and form as good trees in two years, as we could raise here in fifteen or twenty from seed and budding.

They are sold in the Italian warehouses in London, the principal one of which has been for many years in the Hay-market, near the bottom, next Pall-mall, from about three shillings to a guinea a-piece, according to their size, and are generally advertised as

soon as they arrive, which is early in spring, and the sooner the better.

In the choice of these trees observe, they are commonly budded at such height in the stem, as to form heads from about two to four or five feet high; and as they are frequently furnished with two buds, one on each side of the stem, these are what we should chuse, if possible, as they will consequently form the most regular heads.

A bark-bed must be prepared to strike them, either in a glass-case, bark-pit, or some other similar department, where a bed can be made, either in a sunk or raised pit; preparatory to their planting, place the trees half way or more in tubs of water a day or two, to plump their bark and roots, to prepare them for vegetation; then proceed to planting them, first cleaning their roots, and trim them from damaged parts, and all the small dried fibres; likewise wash and clean their stems, and trim the branches of the head to half a foot in length; this done, get the earth and pots; let the earth be rich and moderately light, and the pots proportionate to the size of the roots of the plants; place one tree in each pot, giving water as soon as planted; at the same time, it is of utility to wrap a thin hay-band slightly round each stem, to prevent their outward bark from being parched by the heat of the sun; then let all the pots be regularly plunged to their rims in the hot-bed, prepared, as above, for their reception.

Here they are to remain three or four months; must be frequently, but moderately watered, both at bottom, and over their tops; and as the season advances, and the sun's heat is vehement, it is necessary to shade the glasses a few hours in the middle of sunny days; observing also, that when the heads begin to shoot freely, do not omit giving air, which must be gradually increased, in proportion to the heat of the season, and advanced growth of the shoots; by the beginning of June the heads will be considerably advanced in shooting, at which period observe, if the shoots are but thinly placed, it is eligible to top them, to promote their emitting laterals to form a fuller head; at this time also admit air freely, to harden the shoots gradually, to prepare the trees for being moved to the full air in the middle or latter-end of July; they should then be placed in a situation, defended from boisterous winds, and the violence of the noon-day sun, to remain till the beginning of October; then to be placed in the green-house for the winter, and

and managed as the other trees. See their *General Culture*.

General Culture of all the Sorts.

As to the general culture of all these trees, whether raised in England, or procured from abroad, let it be observed, that, as all the three species and their varieties are so nearly alike in their nature, one common method of culture serves for the whole; they all prosper in any common rich earth or compost, and must all be retained always in pots or tubs, for the convenience of moving them to shelter of a green-house in winter; or the trees may even be planted in the full ground, to be trained either as wall-trees or standards, provided there is a proper frame erected for the support of glass lights, to shield them in winter, and with flues, to make occasional fires in severe weather.

It is necessary to observe, that all the sorts succeed in the open air here, only from the latter end of May until the middle or end of October; the rest of the year require shelter of a green-house, &c.

In the green-house, place the tallest trees behind, and the lowest in front; or, where they are all nearly of a height, those behind should be elevated upon stands, so as their heads may form a sort of gradual slope from the front to the backward row, and, if possible, their heads should stand clear of each other. During their residence in the green-house, the principal care is to give air and water, and secure them from frost; fresh air must be admitted freely every day in all mild calm weather, when not foggy or very wet, by opening the windows less or more, from about eight or nine in the morning, till three, four, or five, &c. in the evening, according to the temperature of the day, giving most air in mild sunny weather: waterings will be necessary during their abode here, about once a week, or ten or twelve days, as you shall see proper; and according to the weather and advanced period of the winter or spring, or power of the sun, and at all times, while in the house, be sure to water moderately, for much moisture at this time would occasion their leaves and young fruit, if any, to grow yellow, and very probably to drop. Their other further care in this department is, chiefly the washing their heads occasionally from filth and insects, clearing off decayed leaves, and protecting them from frost, by securing the windows, &c. the same as di-

rected for the green-house plants in general. See GREEN-HOUSE PLANTS.

In the open air their culture is—towards the latter end of May, or beginning of June, according to the temperature of the season, begin to move these trees in their pots or tubs into the full air, placing them to adorn any particular part of the pleasure ground, observing, when first brought forth, to wash and clean their heads from dust and other filth they may have contracted in the green-house. During the summer season, supply them with water two or three times a week, or oftener, in very hot dry weather, at which time it is proper to lay some mowings of short grass on the surface of the pots or tubs, to preserve the moisture of the earth the better, observing now and then to water all over their heads; with this care they are to be continued in the open air till October, then remove them into the green-house, and manage them as before.

At any time of the year, when the surface of the earth in the pots or tubs binds, it is proper to stir it an inch or two deep; and if this is done in spring, and the loose earth taken out, adding the same quantity of new, it will be very serviceable.

Shifting the plants into larger pots or tubs, and fresh earth, is necessary every second or third spring at most, and April is the proper season; draw them out of their present pots with the ball of earth entire; let all the outside matted mouldy roots be pared off close, and part of the old earth at top, sides, and bottom, taken away: being then prepared with fresh compost, let the pot or tub be cleaned out, or, if a new larger one is necessary, have that ready, and lay some crooked pieces of tiles over the holes at bottom, and put in some earth; then place the tree in the pot or tub, and fill up the vacancy with more compost, pressing it down on every side, finishing the work with a moderate watering, and retain the plants in the green-house till the end of May or beginning of June.

In those years the plants do not require shifting, it is of much utility to loosen the earth in the top of the pots or tubs, as low as the surface of the roots, and down round the sides; taking out the loosened earth, fill up the pot with fresh compost, and give water directly, to settle the earth close.

Any of the trees having thin, straggling, or irregular heads, the way to render them more regular, is to prune all the branches moderately.

moderately short, nearly to an equal length, in March or April; at the same time shifting the plants, as above directed, and they will soon after break forth in the old wood into many young shoots, which you may regulate as you shall see necessary; or, if the shoots arise thinly, some of the strongest may be topped in June, and they will furnish laterals the same year to fill the head.

But such of these trees as have very weak irregular heads, producing small ill-coloured leaves, &c. it is adviseable to prune the head pretty close, and shift the tree into entire fresh earth; that is, shake all the old earth quite from the roots, then prune off all decayed roots and small fibres, and tip the ends of the roots in general, and soak and wash the whole in water, and then plant it in entire new compost, and directly give water; after this it would be of considerable advantage, where convenient, to plunge them in a bark hot-bed, made either in a glass-case, bark-pit, or even in the green house, in which let them remain until July, when they will have made strong shoots, and form a new full and regular head, adorned with fine, large, luxuriant leaves.

When any of the sorts of these trees have obtained a large size, they should be shifted into tubs, hooped with iron hoops, and with two strong hooked iron handles near the top of each tub, to receive poles to lift the trees in and out of the green-house. See TUBS, &c.

The flowering and fruit-setting season of all the sorts of *Citrus* is commonly in June and July; they are often very profuse in flowers, particularly the Orange-tree, which, in healthful large trees, are generally greatly loaded with blossom: when they stand very thick, it is eligible to thin them a little, taking off the smallest; and, observing, as the trees continue blowing and setting their fruit for two months, that, when a full crop of fruit is set, it is of benefit to the trees and fruit, to gather off the superabundant blossom as they are produced, though many permit them to remain for the sake of their ornamental appearance.

The flowers which are thinned off, if they are not wanted for family use, for Orange-flower-water, &c. may, if any quantity of them, be sold to good advantage, i. e. three or four shillings per pound weight; the chymists and perfumers often buy them; but in Covent-garden market in London there is always ready sale for them, either in the open market, or in the physic-herb shops.

Compost, the most proper for all the sorts of *Citrus*, is that of a light loamy nature, though they will all prosper in any rich garden earth. See COMPOSTS.

Of planting them in the full Ground as Wall and Standard-Trees.

In regard to planting these trees in the full ground, as already hinted, observe, that when this is intended, there must be frame-erections for the support of glass and other covers, to defend the plants in inclement weather; and in which situation the trees, as having full scope for their roots, generally shoot strong, and produce large fruit, and may either be trained as wall or standard-trees.

A south wall, in a dry situation, is a proper place for training them as wall-trees, against which may be erected wooden framework sloping, either fixed or moveable, for the support of glass frames for winter; likewise, for the greater protection of the trees in severe frosts, there may be a fire-place, with a flue or two, carried along a low wall in the front and ends; so plant the trees in the full border against the back wall, and train their branches thereto five or six inches distance, observing to defend them with the glasses from October till the middle or end of May, giving air and occasional water as for those in the green-house, and cover the glasses on nights in bad weather, and only in very severe frost employ the flues, if any, with very moderate fires, &c. just to keep out the frost; and in the beginning of June remove the glasses quite away, observing to lightly dig up the borders two or three times a year, and supply them with necessary manure annually.

To have the trees as standards, a more capacious and lofty glass-case should be erected against the wall, in the manner of a hot-house, but higher; so making a border the whole width and length, planting therein one or two rows of trees lengthways, suffering the trees to run up as standards, giving only some necessary pruning, just to preserve regularity; and as to their protection, &c. manage them as above directed.

In some places there are lofty moveable glass-cases, so that two or three rows of trees are planted in a conspicuous part of the pleasure-ground, and in winter the frame is put over them, in summer taken wholly away; so they appear like a little Orange grove growing in the open ground; and if the trees are well protected by the glasses, and other occasional

occasional covers, &c. in winter, they will grow to a much greater height than those in tubs.

CLASSIS, a Class, and in botany is the first and highest division in the arrangement of plants systematically, and by which the whole vegetable kingdom is divided into twenty-four Classes, distinguished by some essential and invariable mark in the fructification, possessed by all the plants of each respective Class; and by the same rule, each Class is subdivided into secondary divisions or orders, the orders into genera, and each genera or genus into species, and the species into varieties. See ORDO, GENUS, SPECIES, and VARIETAS.

A Class, therefore, in botany, is defined to be an assemblage or collection of genera, that have some striking mark in common, derived from the fructification, i. e. generative parts of the flower; as, for instance, one stamina, or male organ. Every genus and species, therefore, having flowers with one stamina, belong to the first Class, (*Monandria*, i. e. of *one* and *a man*); of two stamina, belongs to the second Class, (*Diandria*, i. e. of *two* and *a man*); and of three stamina or male organs, to the third Class, (*Triandria*, i. e. of *three* and *a man*); and so of all the others, as explained under each head in the succeeding arrangement of the twenty-four Classes. Each of these Classes, as above noticed, are subdivided into sections or orders, and that, as the establishment of the Classes, is founded on the number of stamina, or male organs: the orders, or secondary divisions, are founded principally upon the number and situation of the pistil, i. e. style, or female organ, or some other striking part of the fructification; as, for example, we observed above, that all plants having only one stamina, belong to the first Class, *Monandria*; of which Class there are but two orders, the first of which having one style, (*Monogynia*, i. e. of *one* and *a woman*) is *Monandria Monogynia*, one stamina and one style; the second have two styles, (*Digynia*, of *two* and *a woman*) is *Monandria Digynia*, one stamina and two styles: the same is also observable in the second, third, and every succeeding Class, as is sufficiently illustrated in the following arrangement of the twenty-four Classes, and their respective secondary divisions or orders, according to the Linnæan sexual system, as founded on the fructification or sexes of plants. See SEXUS.

First Class.

1. MONANDRIA, of *one* and *a man*, *one male organ*, comprehending plants with hermaphrodite flowers, having but one stamina, or male organ, and of which there are but two orders, these derived from the number of styles in each order.

The orders are,

¹MONANDRIA MONOGYNIA—one stamina and one style.

²MONANDRIA DIGYNIA—one stamina and two styles.

Second Class.

2. DIANDRIA, of *twice*, or *two*, and *a man*, *two male organs*, plants with hermaphrodite flowers, having two stamina, or male organs, and consists of three orders, derived from the number of styles, or female organs, in each order.

The orders are,

¹DIANDRIA MONOGYNIA—two stamina and one style.

²DIANDRIA DIGYNIA—two stamina and two styles.

³DIANDRIA TRIGYNIA—diandrous plants with three styles.

Third Class.

3. TRIANDRIA, of *three* and *a man*, *three male organs*, plants having hermaphrodite flowers, with three stamina, or male organs, and consists of but three orders.

The orders are,

¹TRIANDRIA MONOGYNIA—three stamina and one style.

²TRIANDRIA DIGYNIA—three stamina and two styles.

³TRIANDRIA TRIGYNIA—three stamina and three styles.

Fourth Class.

4. TETRANDRIA, of *four*, &c. comprehends plants having hermaphrodite flowers, with four stamina of equal length, and comprises three orders.

The orders are,

¹TETRANDRIA MONOGYNIA—four stamina and one style.

²TETRANDRIA DIGYNIA—four stamina and two styles.

³TETRANDRIA TETRAGYNIA—four stamina and four styles.

Fifth Class.

5. PENTANDRIA, of *five* and *a man*, *five male organs*, comprises plants having hermaphrodite flowers, with five stamina, and consists of six orders.

C L A

The orders are,

¹PENTANDRIA MONOGYNIA—five stamina and one style.

²PENTANDRIA DIGYNIA—five stamina and two styles.

³PENTANDRIA TRIGYNIA—five stamina and three styles.

⁴PENTANDRIA TETRAGYNIA—five stamina and four styles.

⁵PENTANDRIA PENTAGYNIA—five stamina and five styles.

⁶PENTANDRIA POLYANDRIA—five stamina and many styles.

Sixth Class.

6. HEXANDRIA, of *six* and *a man*, *six male organs*, plants with hermaphrodite flowers, having six stamina, and comprehends five orders.

The orders are,

¹HEXANDRIA MONOGYNIA—six stamina and one style.

²HEXANDRIA DIGYNIA—six stamina and two styles.

³HEXANDRIA TRIGYNIA—six stamina and three styles.

⁴HEXANDRIA TETRAGYNIA—six stamina and four styles.

⁵HEXANDRIA POLYGYNIA—six stamina and many styles.

Seventh Class.

7. HEPTANDRIA, of *seven*, &c. consisting of plants with hermaphrodite flowers, having seven stamina, and furnishes four orders.

The orders are,

¹HEPTANDRIA MONOGYNIA—seven stamina and one style.

²HEPTANDRIA DIGYNIA—seven stamina and two styles.

³HEPTANDRIA TETRAGYNIA—seven stamina and four styles.

⁴HEPTANDRIA HEPTAGYNIA—seven stamina and seven styles.

Eighth Class.

8. OCTANDRIA, of *eight* and *a man*, *eight male organs*, plants with hermaphrodite flowers, having eight stamina, or male organs, and comprehends four orders.

The orders are,

¹OCTANDRIA MONOGYNIA—eight stamina and one style.

²OCTANDRIA DIGYNIA—eight stamina and two styles.

³OCTANDRIA TRIGYNIA—eight stamina and three styles.

C L A

⁴OCTANDRIA TETRAGYNIA—eight stamina and four styles.

Ninth Class.

9. ENNEANDRIA, of *nine*, &c. comprehends plants with hermaphrodite flowers, having nine stamina, and consists of three orders.

The orders are,

¹ENNEANDRIA MONOGYNIA—nine stamina and one style.

²ENNEANDRIA TRIGYNIA—nine stamina and three styles.

³ENNEANDRIA HEXAGYNIA—nine stamina and six styles.

Tenth Class.

10. DECANDRIA, of *ten* and *a man*, *ten male organs*, plants with hermaphrodite flowers, having ten stamina, or male organs, and it consists of five orders.

The orders are,

¹DECANDRIA MONOGYNIA—ten stamina and one style.

²DECANDRIA DIGYNIA—ten stamina and two styles.

³DECANDRIA TRIGYNIA—ten stamina and three styles.

⁴DECANDRIA PENTAGYNIA—ten stamina and five styles.

⁵DECANDRIA DECAGYNIA—ten stamina and ten styles.

Eleventh Class.

11. DODECANDRIA, of *twelve* and *a man*, *twelve male organs*, comprises plants with hermaphrodite flowers, having twelve or more stamina, or male organs, and consists of six orders.

The orders are,

¹DODECANDRIA MONOGYNIA—twelve or more stamina and one style.

²DODECANDRIA DIGYNIA—twelve or more stamina and two styles.

³DODECANDRIA TRIGYNIA—twelve or more stamina and three styles.

⁴DODECANDRIA PENTAGYNIA—twelve or more stamina and five styles.

⁵DODECANDRIA OCTAGYNIA—twelve or more stamina and eight styles.

⁶DODECANDRIA DODECAGYNIA—twelve or more stamina and twelve styles.

Twelfth Class.

12. ICOSANDRIA, of *twenty* and *a man*, or *husband*, *twenty male organs*, consists of plants with hermaphrodite flowers, having about twenty or more stamina, or male organs.

gans, that are inserted either into the inner side of the calix, or to the corolla; by this last circumstance is the Class in question distinguished from that immediately following, *Polyandria*, which have also frequently about twenty stamina, but they are inserted into the receptacle. This Class, *Icosandria*, is also distinguishable by having a monophyllous, hollow, or concave calix, and to the inner side of which the petals are fastened by their claws; and there are five orders.

The orders are,

¹*ICOSANDRIA MONOGYNIA*—twenty or more stamina and one style.

²*ICOSANDRIA DIGYNIA*—twenty or more stamina and two styles.

³*ICOSANDRIA TRIGYNIA*—twenty or more stamina and three styles.

⁴*ICOSANDRIA PENTAGYNIA*—twenty or more stamina and five styles.

⁵*ICOSANDRIA POLYGYNIA*—twenty or more stamina and many styles.

Thirteenth Class.

13. *POLYANDRIA*, of *many and a man*, or *husband*, *many male organs*, plants with hermaphrodite flowers, having many stamina, or male organs, which in this Class are inserted into the receptacle, and which distinguishes it from that immediately preceding, *Icosandria*, where the stamina are also numerous, but are attached to the inner part of the calix, &c. therefore all plants having more than twelve stamina inserted in the *receptaculum* are of this Class, *Polyandria*, and consists of seven orders.

The orders are,

¹*POLYANDRIA MONOGYNIA*—many stamina and one style.

²*POLYANDRIA DIGYNIA*—many stamina and two styles.

³*POLYANDRIA TRIGYNIA*—many stamina and three styles.

⁴*POLYANDRIA TETRAGYNIA*—many stamina and four styles.

⁵*POLYANDRIA PENTAGYNIA*—many stamina and five styles.

⁶*POLYANDRIA HEXAGYNIA*—many stamina and six styles.

⁷*POLYANDRIA POLYGYNIA*—many stamina and numerous styles.

Fourteenth Class.

14. *DIDYNAMIA*, of *twice*, and *power*, *two powers*, comprehends plants with hermaphrodite flowers, having two long and two short stamina: in this circumstance of the stamina, long and short, consists the main

difference between the Class in question, and that of the fourth, which have also four stamina, but which are of equal length; therefore all plants having four stamina that are of unequal length, two of them long, and two short, are didynamous, i. e. of the Class *Didynamia*, of which there are but two families or orders, and are founded upon the absence and presence of the *pericarpium*, or seed-vessel.

The orders are,

¹*DIDYNAMIA GYMnospermia*—two long and two short stamina, and naked seeds (*gymnospermia*) lodged in the calix.

²*DIDYNAMIA Angiospermia*—two long and two short stamina, and covered seeds (*angiospermia*) lodged in a proper pericarpium, or seed-vessel.

Fifteenth Class.

15. *TETRADYNAMIA*, of *four*, and *power*, *four powers*, plants with hermaphrodite flowers, having four long and two short stamina, and consists of two orders, founded on the pericarpium; such as have a short round pod, (*siliculosa*) as honesty and Candy tuft, and such as have a long pod (*siliquosa*), as stock-gilliflower, &c.

The orders are,

¹*TETRADYNAMIA SILICULOSA*—four long and two short stamina, and short round pods.

²*TETRADYNAMIA SILIQUOSA*—four long and two short stamina, and long seed-pods.

Sixteenth Class.

16. *MONADELPHIA*, of *alone* and *a brotherhood*, *one brotherhood*, hermaphrodite flowers, having all the stamina united below into one body, forming a column, through which passes the style; and the orders are five, founded on the number of united stamina.

The orders are,

¹*MONADELPHIA PENTANDRIA*—five monadelphous stamina.

²*MONADELPHIA DECANDRIA*—ten monadelphous stamina.

³*MONADELPHIA ENDECANDRIA*—eleven monadelphous stamina.

⁴*MONADELPHIA DODECANDRIA*—twelve or more monadelphous stamina.

⁵*MONADELPHIA POLYANDRIA*—numerous monadelphous stamina.

Seventeenth Class.

17. *DIADELPHIA*, of *twice* and *a brotherhood*, *two brotherhoods in the same flower*, hermaphrodite flowers, having two sets or columns

columns of united stamina, i. e. united below into two different bodies; the flowers are all papilionaceous, and have apparently ten stamina, but which are only two, one of which splits longitudinally from the middle upward, and terminates in about nine parts, appearing like so many distinct filaments; and the other stamina is simple or undivided, and lies closely along the fissure of the divided filament, which have generally as many antheræ as divisions, and the simple stamina have but one antheræ; and from the number of antheræ in both filaments is founded the orders, which are four.

The orders are,

¹DIADELPHIA PENTANDRIA—diadelphous stamina, having five antheræ.

²DIADELPHIA HEXANDRIA—diadelphous stamina with six antheræ.

³DIADELPHIA OCTANDRIA—diadelphous stamina with eight antheræ.

⁴DIADELPHIA DECANDRIA—diadelphous stamina with ten antheræ.

Eighteenth Class.

18. POLYADELPHIA, of many brotherhoods, many brotherhoods, or unions of stamina, in the same flower, hermaphrodite flowers that have each many sets of united stamina, i. e. united by their filaments into several distinct bodies, and consists of three orders, derived from the number of stamina or antheræ, appearing in each flower.

The orders are,

¹POLYADELPHIA PENTANDRIA—five polyadelphous stamina in each set.

²POLYADELPHIA ICOSANDRIA—twenty polyadelphous stamina.

³POLYADELPHIA POLYANDRIA—many polyadelphous stamina.

Nineteenth Class.

19. SYNGENESIA, of together and generation, plants with compound flowers, having all the antheræ, or generative male organs, united into one cylindric body, and through which the style, or generative female organ, rises, uniting in the same manner.

This Class contains the numerous tribe of compound flowers, see COMPOSITUS *Flos*; and the orders, or secondary divisions, arise from the different modes of intercommunication, or polygamia of the florets that compose each flower; such as, the florets all hermaphrodites—hermaphrodites and females—hermaphrodites of no sex or neuter—males and females—the florets in distinct cups within the main one—simple florets; so that this Class is divided into six orders.

The orders are,

¹SYNGENESIA POLYGAMIA ÆQUALIS—equal polygamia, or the florets all hermaphrodites.

²SYNGENESIA POLYGAMIA SUPERFLUA—superfluous polygamia, or the florets of the disk all hermaphrodites, and the circumference or radius all females, which latter are said to be superfluous or useless, because the impregnation of them is unnecessary, the fructification being completed in the hermaphrodites in the centre.

³SYNGENESIA POLYGAMIA FRUSTANEA—frustrated polygamia, i. e. the florets in the radius are neuter, or of no sex, being devoid both of stamina and style, so are ineffectual to the fructification, as in the case of sunflower, &c. in which the fructification is perfected only, in the hermaphrodites, in the disk.

⁴SYNGENESIA POLYGAMIA NECESSARIA—necessary polygamia, or being male and female florets, and no hermaphrodites, the presence of the male and females is necessary for perfecting the fructification.

⁵SYNGENESIA POLYGAMIA SEGREGATA—separated polygamia, the florets of each flower separated from each other by means of partial cups, containing one or more florets, and stand within the general calix, as in globe-thistle and elephant's-foot.

⁶SYNGENESIA POLYGAMIA MONOGAMIA—monogamous or simple florets, the flower having only one floret in each general calix, as in balsamine, *impatiens*.

Twentieth Class.

20. GYNANDRIA, of a woman and a man, plants having the stamina or male organs placed either upon the style or female organ, or the common receptacle elongated in the form of a style, supporting both the pistillum and stamina; and is divided into seven orders, founded each on the number of stamina in each flower.

The orders are,

¹GYNANDRIA DIANDRIA—two gynandrous stamina in each flower.

²GYNANDRIA TRIANDRIA—three gynandrous stamina in each flower.

³GYNANDRIA TETRANDRIA—four gynandrous stamina in each flower.

⁴GYNANDRIA PENTANDRIA—five gynandrous stamina in each flower.

⁵GYNANDRIA HEXANDRIA—six gynandrous stamina in each flower.

⁶GYNANDRIA DECANDRIA—ten gynandrous stamina in each flower.

⁷GYNANDRIA

⁷GYNANDRIA POLYANDRIA—many gynandrous stamina in each flower.

Twenty-first Class.

21. MONOECIA, of *alone* and *a house*, plants with male and female flowers apart, or alone, in separate cups; that is, within different cups on the same plant, as in the cucumber, &c. and is divided into eleven orders, arising from the number, union, and situation of the stamina of the male flowers.

All monoecious plants are also termed androgynous, from the same circumstances of male and female flowers on different parts of the same plant. See ANDROGYNIA.

The orders are,

¹MONOECIA MONANDRIA—monoecious plants with one stamina.

²MONOECIA DIANDRIA—monoecious plants with two stamina.

³MONOECIA TRIANDRIA—monoecious plants with three stamina.

⁴MONOECIA TETRANDRIA—monoecious plants with four stamina.

⁵MONOECIA PENTANDRIA—monoecious plants with five stamina.

⁶MONOECIA HEXANDRIA—monoecious plants with six stamina.

⁷MONOECIA HEPTANDRIA—monoecious plants with seven stamina.

⁸MONOECIA POLYANDRIA—monoecious plants with numerous stamina.

⁹MONOECIA MONADELPHIA—monoecious plants with monadelphous or united stamina, i. e. all the stamina united below into one cylindric body.

¹⁰MONOECIA SYNGENESIA—monoecious plants with syngenesious antheræ; that is, with all the antheræ, or tops of the stamina, united into a cylinder, as in the cucumber, gourd, bryony, &c. See Class SYNGENESIA.

¹¹MONOECIA GYNANDRIA—monoecious plants with gynandrous stamina, i. e. the filaments situated upon a sort of imperfect style. See the Class GYNANDRIA.

Twenty-second Class.

22. DIOECIA, of *twice* and *an habitation*, *two habitations*, male and female flowers on two separate plants; that is, all the plants of this Class are either male or female, not hermaphrodite, as in the greater number of Classes; nor with male and female on the same plant, as in the immediately preceding Class, *Monoecia*, but male and female flowers on distinct plants, as in the genus *cliffortia*, *coriaria*, *carica*, moonseed, spinach, hop, and many others; and the female plants only pro-

duce seeds, which, however, require the vicinity of a male plant, or the asperision of the male dust to impregnate the female flowers, or at least to render the seeds fertile; and from the seeds of the females, both male and female plants are produced.

This Class is divided into fourteen orders, and are founded upon the number, union, and situation of the stamina of the male plants.

The orders are,

¹DIOECIA MONANDRIA—dioecious male plants with one stamina.

²DIOECIA DIANDRIA—dioecious male plants with two stamina.

³DIOECIA TRIANDRIA—dioecious male plants with three stamina.

⁴DIOECIA TETRANDRIA—dioecious male plants with four stamina.

⁵DIOECIA PENTANDRIA—dioecious male plants with five stamina.

⁶DIOECIA HEXANDRIA—dioecious male plants with six stamina.

⁷DIOECIA OCTANDRIA—dioecious male plants with eight stamina.

⁸DIOECIA ENNEANDRIA—dioecious male plants with nine stamina.

⁹DIOECIA DECANDRIA—dioecious male plants with ten stamina.

¹⁰DIOECIA DODECANDRIA—dioecious plants with twelve stamina.

¹¹DIOECIA POLYANDRIA—dioecious male plants with numerous stamina.

¹²DIOECIA MONADELPHIA—dioecious male plants with monadelphous or united stamina, being united by their filaments into a pillar or column, as in shrubby horse-tail.

¹³DIOECIA SYNGENESIA—dioecious male plants with syngenesious antheræ, i. e. with the antheræ or tops of the filaments united.

¹⁴DIOECIA GYNANDRIA—dioecious male plants with gynandrous stamina, or that are situated on a kind of style. See the Class GYNANDRIA.

Twenty third Class.

23. POLYGAMIA, of *many* and *marriage*, plants of a variety of sexes, that is, hermaphrodite flowers, and likewise male or female flowers, or both on the same plant, or on distinct plants of the same genus; and from the different circumstances of polygamia this Class is divided into three orders.

The orders are,

¹POLYGAMIA MONOECIA—the polygamia all on the same plant.

²POLYGAMIA DIOECIA—the polygamia on two distinct plants.

³POLY-

¹POLYGAMIA TRIOECIA—the polygamia on three distinct plants.

Twenty-fourth Class.

24. CRYPTOGRAMIA, of *to hide or conceal* and *a marriage, a clandestine marriage*,—plants that have their fructifications either entirely concealed, or, from their minuteness or situation, are imperfectly visible: such are the ferns, mosses, flags, sea-weed or wrack, and mushrooms, and of which the classic character is very imperfect, and the genera of course without any essential mark or distinction, so great is the obscurity that still prevails in this considerable part of the vegetable kingdom.

This Class of imperfect plants is divided into four orders or families, very different in their general habit.

The orders are,

¹CRYPTOGAMIA FILICES—the *Filices* or Ferns.

This is a large tribe of plants, defined to be plants which bear their flower and fruit on the back of their leaves; but the flower and other parts of fructification are so minute, or imperfectly visible, that they do not admit of any regular classic distinction. See FILICES.

²CRYPTOGAMIA MUSCI—*Musci* or Mosses.

This is also a large tribe of plants with imperfectly distinguishable fructifications: their chief characteristic distinction is—antheræ without filaments—male flowers, constituted by the presence of the antheræ—the antheræ have, or are destitute of a *calyptra*—seeds entirely naked, being devoid of the cotyledon or cover, so exhibit the naked embryo. See MUSCI.

³CRYPTOGAMIA ALGÆ—*Algæ*, Flags or Sea-weed.

A numerous tribe of imperfect plants, whose root, stem, and leaf are all one, and their fructification imperfectly known.

⁴CRYPTOGAMIA FUNGI—*Fungi*, or Mushrooms.

A very extensive tribe of plants, whose fructification is still entirely unknown. See FUNGI.

By the foregoing arrangement of the twenty-four Classes of the vegetable kingdom, and their respective orders, the student in gardening and botany will easily explain to himself the proper Class and order of all the different genera; especially, as to each genus we have all along subjoined the name of the Class and order to which it belongs; ob-

serving, that all the different species and varieties of each genera or genus, are also all of the same Class and order.

CLEMATIS, Climber, or Virgin's-Bower, and Traveller's-Joy, &c.

This genus furnishes several shrubby climbers of the flowery tribe, and two herbaceous, upright, flowery perennials, all of hardy growth; adorned some with winged, others with divided, and some with simple leaves; and all of them with quadripetalous flowers.

Class and order, *Polyandria Polygynia*.

Characters.] CALIX none. COROLLA, four oblong loose petals. STAMINA, numerous awl-shaped filaments, with the antheræ growing to their sides. PISTILLUM, numerous, roundish, compressed germina, subulated styles, and simple stigmas. PERICARPIUM none. SEMINA, numerous roundish seeds, collected into a head, with the styles adhering thereto.

The species are as follow.

The first seven species are shrubby climbers, having slender stalks and branches, climbing or mounting themselves on support by *cirrhus* or claspers, many feet high.

¹CLEMATIS *Viticella*.

Viticella, or *Virgin's-Bower Clematis*.] Clematis with shrubby climbing stalks, branching at every joint, and mounting upon support fifteen or twenty feet high; compound and decomposed leaves of many oval entire lobes, and numerous slender foot-stalks by threes, each supporting one flower, of different colours in different varieties.

Varieties are] Virgin's-Bower with single blue flowers—single red flowers—single purple flowers—double purple flowers; all of them appearing in July and August.

This species and varieties obtain the name Virgin's-Bower, from their peculiar excellence in forming arbours or bowers, &c. they being admirable climbers, and often shoot ten or fifteen feet in one year, spreading their branches numerously every way, and very closely covered from bottom to top with leaves and flowers; but the double-flowered variety is the most beautiful, its petals being so numerous as to obliterate the fructification, and continues the longest in bloom. They are all well calculated for training over covered arbours, or rural seats, or against naked walls or other fences.

²CLEMATIS *Vitalba*.

Vitis-alba, *Great White Climber*, *Traveller's-Joy*, and *Old Man's Beard*.] Clematis with shrubby, tough, climbing stalks, very branchy and

and cirrhous, mounting upon support twenty feet high, garnished with winged climbing leaves of five or seven heart-shaped lobes, and numerous bunches of white flowers, succeeded by compact clusters of seeds, terminated by long white hairy plumes, hanging down like beards; hence sometimes called Old Man's Beard.

It grows wild in England in hedges, mounting by its numerous clasps over the bushes and trees in its neighbourhood, spreading widely every way, that the hedges are often covered with its flowers in summer, and its white-bearded seeds in autumn and winter, appearing singular and ornamental, whereby, as growing abundantly by road sides, affording entertainment to passengers, is also called Traveller's-Joy; it is rarely admitted in gardens, though a few plants, properly disposed in large shrubbery-works, will have an agreeable effect as climbers.

¹CLEMATIS *Viorna*.

Viorna, or Virginian Purple Climber.] Clematis with shrubby climbing stalks, branching and rising on support eight or ten feet high; compound and decomposed leaves of nine nearly heart-shaped, sometimes trifid lobes; and purplish-blue flowers, having thick coriaceous petals, appearing in July and August.

⁴CLEMATIS *Orientalis*.

Oriental Yellow Climber.] Clematis with shrubby climbing stalks and branches, mounting upon support six or eight feet high; compound leaves of nine folioles, cut angularly into wedge-shaped lobes; and yellowish green flowers in April and May.

⁵CLEMATIS *Virginiana*.

Virginian Ternate-leaved White Climber.] Clematis with shrubby climbing stalks and branches, rising on support many feet high; ternate or trifoliate leaves, of three heart-shaped, angular, lobated lobes, and white flowers.

⁶CLEMATIS *Crispa*.

Carolina Curled-flowered Climber.] Clematis with shrubby climbing stalks, branchy, and rising upon support four or five feet high; simple and trifoliate leaves, the folioles in some entire, others divided into three lobes; and purple flowers, having thick curled petals, appearing in July and August.

⁷CLEMATIS *Cirrhosa*.

Cirrhose Evergreen Climber.] Clematis with shrubby climbing stalks, very branchy, bushy, and cirrhous, mounting upon support six or eight feet high; simple evergreen leaves, some-

times bifid, and some cut into three lobes; and greenish flowers, appearing in winter.

The two following are herbaceous, and of upright growth.

⁸CLEMATIS *Recta*.

Upright White Clematis.] Clematis with fibrey perennial roots; upright annual stalks a yard high; winged opposite leaves of three or four pair of oval-spear-shaped entire lobes, terminated by an odd one; and at top of the stalks, white flowers in large panicles, appearing in June.

Variety.] Low upright white Clematis with large flowers.

⁹CLEMATIS *Integrifolia*.

Upright Entire-leaved Blue Clematis.] Clematis with fibrey perennial roots; upright annual stalks a yard high; large, simple, spear-shaped, entire leaves, growing opposite; and from the upper part of the stalks, many long naked foot-stalks, each supporting a large blue flower, appearing in June.

The flowers of all the species, in their natural single state, are composed each of four oblong petals, and in all the climbing kinds are remarkably numerous, arising from almost every part of the branches at the axillas of the leaves, succeeded, in several of the climbers, and both the upright herbaceous sorts, with abundance of seed in autumn, growing in clustered heads, all of which, being furnished with long white plumes, have a singular appearance in autumn and winter.

All the species, both climbers and upright kinds, are very hardy, and prosper in any common soil of a garden, and in any exposure.

The first seven sorts are of climbing growth, and having durable stalks, but which being long, slender, and weak, must have support either of trellis-work, strong stakes, walls, paling, or hedges, &c. otherwise their branches will trail on the ground; so that they are proper to train over covered arbours, or against high naked walls, or the like; or may be introduced in large shrubbery or wood-works, here and there one, to run over the bushes; and some may also be planted singly in large clumps between deciduous shrubs, placing tall strong stakes for their support.

Of these climbing kinds, the first sort, Virgin's-Bower and varieties, have the greatest merit for ornament, and are the sorts that are principally known and cultivated in the British gardens.

The eighth and ninth sorts are proper furniture

niture for any of the compartments of the pleasure-ground, and they will succeed any where; they are particularly well calculated to occupy vacant spaces in the shrubby clumps, where they will shew themselves to great advantage.

Propagation of all the Sorts.

All the shrubby climbing kinds are propagated by layers, and some of them also by cuttings.

By layers: the young shoots of the same year are the proper parts for propagation, and if these are layed in summer, before they become woody, they will more certainly succeed; therefore, when the shoots of the year are two or three feet long, let the branches on which they grow be brought down and pegged in the ground; then lay all the young shoots in the earth, in the usual way, with their tops three or four inches out, and by October most of them will be rooted, when, or in spring following, they may be transplanted into the nursery.

This method of summer laying is more particularly necessary for the Virgin's-Bower and varieties, and most of the foreign climbers.

The Traveller's-Joy and Evergreen Climber, however, may be layed at any time; they will also grow by cuttings of the young shoots in spring or summer, though those of the latter rather require aid of a hot-bed; and the Evergreen sort often send up suckers from the bottom, each of which, transplanted, becomes a good plant.

The two upright herbaceous sorts are easily propagated, by dividing their roots in autumn, or early in spring, which multiply exceedingly, and may be divided every two or three years; every slip having a fibre at bottom, and bud at top, will readily grow.

These two sorts may also be raised from seeds, in a bed or border of common earth, sown in autumn, or early in spring; and when the plants are a year old, they will produce flowers.

CLETHRA, *Clethra*.

There is but one species, a deciduous flowering shrub for the shrubbery.

Class and order, *Decandria Monogynia*.

Characters.] CALIX, monophyllous, five-parted, and permanent. COROLLA, five oblong petals, broadest towards the extremities. STAMINA, ten filaments, and oblong erect antheræ. PISTILLUM, roundish ger-

men, permanent style, and trifid stigma. PERICARPIUM, a roundish, trivalvular, trilocular capsule, lodged in the calix, and many angular seeds.

The species is,

CLETHRA *Alnifolia*.

Alder-leaved American Clethra.] Clethra with a shrubby stem, dividing into a branchy head four or five feet high; long, spear-shaped, serrated, alternate leaves; and at the ends of the branches long spikes of white flowers in July or August.

This is a very ornamental shrub, but more particularly during its bloom, and merits a place in every curious collection, allowing it rather a moist than dry soil.

It is propagated by seeds, layers, and suckers.

By seeds: these are procured from America, and sown in pots of light earth, to move to shade in summer, and shelter in winter, because the plants sometimes do not come up till the second spring. By layers: perform it on the young shoots in autumn; water them the following summer, and by autumn after they will be rooted, though it is sometimes two years before that is accomplished. Suckers from the root may be transplanted in autumn or spring, being careful to take them up with fibres.

CLIFFORTIA, *Cliffortia*.

It furnishes three evergreen African shrubs for the green-house, adorned with simple and trifoliate leaves, and apetalous flowers.

Class and order, *Dioecia Polyandria*.

Characters.] CALIX, male and female flowers on separate plants, having cups composed of three oval acute leaves; those of the females are permanent. COROLLA, no petals. STAMINA, numerous erect filaments in the males, and oblong, twin, compressed antheræ. PISTILLUM, in the females, an oblong germen under the calix, two plumose styles, and simple stigmas. PERICARPIUM, an oblong, taper, bilocular capsule, crowned by the calix, and contains one seed.

The species are,

¹**CLIFFORTIA** *Illicifolia*.

Ilex-leaved Cliffortia.] Cliffortia with a shrubby slender stem, very branchy, and forming a diffused head four or five feet high; stiff leaves, heart-shaped at the base, broad and indented at the ends; and yellowish-green close-fitting flowers, growing singly.

²**CLIFFORTIA** *Ruscifolia*.

Ruscus-leaved Cliffortia.] Cliffortia with a shrubby

shrubby slender stalk, forming a branchy head three or four feet high; small, spear-shaped, stiff, entire leaves, in clusters; and between them loose bunches of yellowish green flowers.

³CLIFFORTIA *Trifoliata*.

Three-leafed Cliffortia.] Cliffortia with a shrubby very slender stem, branching and forming a spreading head three or four feet high; trifoliate close-fitting leaves, having the middle lobe tridented, and yellowish-green flowers almost close to the branches.

The flowers of all the species are apetalous, so make no great appearance, but are the most conspicuous in the male plants, by their numerous, yellow, erect stamina.

All the three species, considered as evergreens, are very ornamental, and being natives of *Æthiopia*, require shelter here in winter; so must be kept in pots of rich light earth, and placed in the greenhouse collection, giving plenty of water in summer, and but very sparingly in winter.

Their propagation is generally effected by cuttings in this country, which must be young shoots of five or six inches length, planting them in pots in spring or summer, and plunge them in a hot-bed, they will readily take root.

They may also be propagated by layers in the spring.

CLIMBING PLANTS, plants whose stalks either ascend spirally round any adjacent support, or climb by means of clasps or tendrils. See CIRRHUS.

Of Climbers, there are both herbaceous and woody plants, and which may be divided into three kinds, according to their mode of climbing; such as Twining Climbers, Cirrhose Climbers, Parasitic Climbers.

Twining Climbers; such as have winding stalks (*caulis volubilis*) and which twist or ascend themselves spirally about any neighbouring support, as scarlet kidney beans, hops, convolvulus major, and some species of honeysuckle.

Cirrhose Climbers; such that ascend thro' means of clasps, tendrils, or spiral strings, issuing from the sides of the stalks and branches (*cauli cirrhosus*), or from the foot-stalks of the leaves, and even from the leaves themselves, so twist about any thing they encounter, whereby their stalks are supported and arrive at the height nature designed them: examples of this sort are, almost all the pea tribe, cucumber, vine, passion-flower, travel-

ler's-joy, *smilax*, or rough bindweed, and many other sorts.

Parasitic Climbers; these are also of the cirrhose tribe, but their cirrhi, or clasps, plant themselves like roots in the bark of the adjoining trees (*cauli parasiticus*), so the plant thereby supports itself like a parasite, on other plants, and mount to their tops; such as the ivy, radican bignonia, woody nightshade, and several others: these sort of Climbers also root in walls, pales, or any kind of buildings, and ascend to their tops, if ever so high.

Many of the climbing and trailing tribe are very ornamental in gardens, both of the herbaceous and shrubby kinds; the following is a list of the principal sorts.

Of the herbaceous kinds are, *convolvulus*, several species and varieties—everlasting-pea—painted-lady-pea—*cynanchum*, several species—scarlet kidney-bean, and white varieties—nasturtium—gourd—hop-plant—*tamus*, or black briony—Cretan black briony—*brionia*, or white-briony—*ipomoea coccinea*, or scarlet convolvulus, and some others.

All these herbaceous Climbers may be allowed places in large borders, placing sticks for their support, upon which most of them will naturally climb, and appear very ornamental in summer.

Some of the more aspiring sorts may also be placed to run over arbours, or any kind of rural seats in gardens.

Of shrubby kinds, or such as have perennial stalks, are the following: radican and evergreen *bignonia*—climbing *celastrus*—*clematis*, virgin's-bower, several species and varieties—*glycine*, or kidney-bean-tree of Carolina—ivy—honeysuckle, many sorts—*monispermum*, or moon-seed, two or three species—*passiflora*, or passion-flower—*periploca*, or Virginia-silk—*rubus*, or bramble, several sorts—*smilax*, or rough bindweed—woody nightshade, two or three varieties—*vinca*, or periwinkle, many varieties—*vitis*, the vine.

All these shrubby Climbers, considered as plants of ornament, are proper furniture for shrubberies of any considerable extent, and may be employed different ways; some may be dispersed about the clumps, detached from the other plants, so placing strong tall stakes for their support, and they will have a singular effect among the other shrubs; others may be stationed near hardy trees and large shrubs, and suffered to climb about their stems, or interweave in their branches, and aspire to their

their tops or extremities, and spread about in their natural way, when they will have a beautiful effect in forming rural variety; some may also be employed to ornament naked or unsightly walls of high buildings, and some for decorating or forming rural arbours, where there is lattice, or any kind of open-work, for the branches to climb upon, which, in many of the sorts, will shoot ten or fifteen feet in a summer; so that an arbour may be formed in one season.

But for particulars of the different sorts, and their culture, see their respective genera.

CLUTIA, *Clutia*.

This genus furnishes three shrubby-succulent evergreen exotics for the green-house and stove, garnished with simple leaves, and greenish-white quinquepetalous flowers.

Class and order, *Diœcia Gynandria*.

Characters] CALIX, male and female flowers on separate plants, having cups composed of five large, oval, concave leaves. COROLLA, five heart-shaped, spreading, permanent petals, and at the bottom five nectariums placed circularly; and in the males five small ones within the others. STAMINA, five horizontal filaments, situated in the middle of a style, and roundish versatile antheræ. PISTILLUM, in the males no germen, but a long staminiferous style; in the females a roundish germen, and three bifid styles, and obtuse stigmas. PERICARPIUM, a globular, six furrowed, trilocular capsule, and three seeds.

The two first species are green-house exotics.

¹CLUTIA *Alaternoides*.

Alaternoides Ethiopian Clutia.] Clutia with a shrubby stem, branching laterally and erect, forming a head six or eight feet high; very narrow, spear-shaped, close fitting, greyish, alternate leaves; and from their axillas, solitary, small, greenish-white, erect flowers.

²CLUTIA *Pulchella*.

Purshane-leaved Ethiopian Clutia.] Clutia with a shrubby stem, branching from the sides erectly six or eight feet high; oval, entire, sea green, alternate leaves, on foot stalks; and small greenish-white flowers along the sides of the branches.

The following is a stove exotic.

³CLUTIA *Eluteria*.

Eluteria, or Indian Clutia.] Clutia with a shrubby stem, branching erectly five or six feet high; heart-shaped-lanceolate, pointed, foot-stalked, alternate leaves; and flowers in spikes at the ends of the branches.

The flowers of these three species are formed each of five small petals, appearing in June, July, and August, but are not very ornamental; so that the merit of the shrubs is in their beautiful evergreen leaves.

The two first sorts are green-house plants, and the other is of the stove, so must always be kept in pots of light rich earth; though they will all succeed in the open air in summer, and being always green, they are very ornamental at all seasons.

Their propagation is by cuttings in spring or summer, planting them in pots of light earth, and plunge them in a hot bed, they will readily emit roots, and must be transplanted into separate pots.

CNEORUM, *Widow-Wail*.

There is but one species, a low evergreen shrub for the shrubbery, adorned with simple leaves, and tripetalous flowers.

Class and order, *Triandria Monogynia*.

Characters.] CALIX is monophyllous, tridentate, and permanent. COROLLA, three oblong, spear-shaped, erect petals. STAMINA, three short filaments, and small antheræ. PISTILLUM, a blunt trigonous germen, firm style, and trifid stigma. PERICARPIUM, a globular, trilobate, trilocular, dry berry, and three seeds.

The species is,

CNEORUM *Triccocum*.

Triccocus Cneorum.] Cneorum with a shrubby hard stem, divided low into a branchy bushy head two or three feet high, closely garnished with oblong-oval, close-fitting, stiff leaves, two inches long, and half an inch broad; and from their axillas, towards the ends of the branches, yellowish flowers, growing singly, succeeded by triccocus, three-seeded, baccaceous fruit.

It flowers from May till October, and affords plenty of ripe seed.

This is a very ornamental little evergreen for the fronts of the shrubbery clumps, though it is sometimes retained as a green-house plant; but this is needless, unless merely for the sake of variety, for it will prosper freely in the full air the year round, observing to allow it a dry soil, in which it will endure the rigours of severe winters, better than in rich moist ground.

The propagation of this shrub is by seeds and cuttings

By seeds: sow them in a bed of common earth half an inch deep in October, and most of the plants will rise the spring following, the

the largest of which, in the spring after, may be thinned out, and planted in the nursery-way, and in two or three years they will be ready for the shrubbery, &c.

By cuttings: this may be done in spring, cutting or slipping off some of the former year's shoots five or six inches long; plant them in a pot of good earth, and plunge them in a hot-bed, they will soon root and set to growing: young shoots, planted in a shady border in July, or early in August, will also grow.

COCHLEARIA, Spoonwort, or Scurvy-Grass, and Horfe-Radish.

The plants are herbaceous and hardy, and of which there are two species that merit culture; one of them a fibrous-rooted biennial for medicine; the other a carrot-rooted perennial, valuable for its root as an esculent, well known by the appellation of Horfe-Radish.

It may to some appear strange to see Horfe-Radish retained as a species of Scurvy-Grass, but its general characters certainly declare it of that genus.

Class and order, *Tetradynamia Siliculosa*.

Characters.] **CALIX**, four oval concave leaves. **COROLLA**, four oval, spreading, cruciforme petals. **STAMINA**, four long, and two short filaments, and obtuse compressed antheræ. **PISTILLUM**, a heart-shaped germen, short style, and obtuse stigma. **PERICARPIUM**, a heart-shaped, gibbous, compressed, bilocular pod, affixed to the style, and eight seeds.

The species of our gardens are,

¹**COCHLEARIA Officinalis**.

Common Officinal Scurvy Grass.] **Cochlearia** with a fibrous root, crowned by a cluster of round succulent leaves, hollowed like a spoon, and amongst them branchy stalks ten or twelve inches high, garnished with oblong sinuated leaves, and at the ends of the branches clusters of small white flowers.

It flowers in April and May, succeeded by plenty of seeds in June.

²**COCHLEARIA Armoracia**.

Armoracia, or Horfe-Radish.] **Cochlearia** with a long, thick, perpendicular, white root, crowned by large, spear shaped, erect leaves; and between them an upright stalk, garnished with small jagged leaves, and terminated by white flowers.

The first sort, *Cochlearia Officinalis*, is a medical herb, and its virtue resides in the

leaves and stalks. It may be considered both as an annual and biennial, and its propagation is by seed annually in spring or autumn, in any situation, sowing it on the surface, and rake it in, which, if sown in autumn soon after it ripens, i. e. in July, or beginning of August, the plants will rise soon after; thinning them to three or four inches, and they will stand the winter, and be fit for use in spring.

The second species, *Horfe-Radish*, is in much esteem for its eatable root, which is used raw, scraped into fine shreds, and is either used alone as sauce to flesh meat, or incorporated in fallads, and is also used for garnish to dishes, &c.

It is a very hardy plant, is perennial in root, and its nature of growth is—The bottom of the root generally resolves itself into a thick, knotty, durable stool, at a certain depth in the ground, and from which arise several erect root-shoots, advancing perpendicularly to the surface of the earth, which, after having one or two years growth, acquire a substance of one or two inches thickness, and that being taken up for use, the stool remaining sends up a fresh supply the year following; therefore, in the culture of this plant, it is necessary to plant the roots twelve or fifteen inches deep in the ground, to form stools that depth under the surface, that they may send up long, strait, regular shoots, which, arising in spring, continue encreasing in substance till September or October, when, in rich ground, they probably will be large enough for use, i. e. about an inch thick; but if they are much smaller, permit them to have another summer's growth, observing, when you take them up, to trench the ground open to the depth of the stool; so cutting off the young shoots close to the place from whence they proceed, always leaving the old stools undisturbed, and they will furnish you with a fresh crop, as above, annually.

The propagation of this plant is by roots, cuttings of which, taken from the top an inch or two long, or even any part of the root cut into sets that length, each having an eye or bud, will readily grow and become a plant.

But although any part of the root will thus readily grow, the best sets for planting are cuttings taken from the top of the roots with the head or crown to them, either of the principal roots, or their off-sets or side-shoots, as also the small off-sets arising immediately from

from the stools; therefore, when intended to make a fresh plantation, it is proper, according as the roots are taken up occasionally for use, to reserve a quantity of the largest off-sets, and lay them in the earth till wanted; then cut the tops off for planting two or three inches long; the tops of the main roots may also, when taken up, be cut off an inch or two long, and preserved as above for the same purpose; but this latter is only practicable in private gardens; for, if the kitchen-gardeners were to cut off the tops of their marketable roots, it would render them unsaleable; so, in this case, recourse is commonly had to the off-sets above described.

The season for planting them is any time in open weather from November till spring, though I should rather prefer the month of February or beginning of March, especially in wet or stubborn ground.

As to the soil proper for their culture, observe, that although the plants will grow in almost any soil and situation, yet to have long strait roots of considerable substance, a rich, moderately-light, deep soil, in an open exposure, should, where possible, be chosen, and which should be regularly trenched two moderate spades deep, well breaking all large clods, that nothing may obstruct the perpendicular growth of the roots.

The method of planting is:—the sets or cuttings are to be planted in rows two feet deep, nine inches distance in the lines, and each cutting placed twelve or fifteen inches deep, for the reason already hinted, and may either be planted by dibber, after the ground is dug, or they may be trenched in, placing them in the bottom of the trenches as you proceed in trenching. But, first, of planting by dibber, which is the method I prefer for general practice: the ground being dug a due depth, as before directed, and the surface laid level, then begin at one end, and strain a line cross-ways the ground, and having a long dibber, make holes therewith fifteen inches deep, and nine asunder, and as you go on, drop one set or cutting in each hole, with the top or crown upright, striking in the earth upon them; one row being thus planted, move the line two feet farther, and plant another in the same manner, and so proceed to the end. Next, with regard to the method of planting by trenching them in:—The ground is to be trenched in the usual way, beginning therefore at one end of the piece, and open a trench two

spades wide, and one deep, and dig the bottom; then by line set a row of cuttings along the middle of the bottom nine inches distance, thrusting them up to their tops in the earth, and then dig the next trench the same width and depth, turning the earth thereof into the first upon the row of plants, breaking all large clods, and level the top; then digging the bottom of this second trench, plant another row of cuttings as above, covering them with the earth of a third trench; and in this manner proceed till the whole is planted, levelling the surface as you go on in a regular manner.

When the whole is planted in either of the above methods, the ground may be sown with spinach and radishes, or any slight-rooting temporary crop, that comes off early in summer, by the time the Horse-Radish appears, which, as they have to shoot quite from the bottom, they rarely make their appearance the first year before the middle of May, when all other crops must be cleared off, and the ground hoed to destroy weeds, and the leaves of the Radish will soon cover the ground, and no further care will be required till the roots are fit to take up for use.

In October following you may examine the roots; sometimes they will make such progress, as to be large enough for use; but if they, however, are not greatly wanted, they will be in excellent order by that time twelve-month.

When the roots are to be taken up for use, begin at the first row, and open a trench two feet wide, and as deep as the stool or bottom of the roots, but without disturbing them; then with your knife cut off all the shoots, large and small, of each stool, close and level to the place from which they arise, leaving the stool in the ground; and when you have taken up all the plants of the first trench, then proceed to the next row; open another trench, turning the earth into the first, and cut off all the shoots of this row as before; and in like manner continue taking up the whole, according as they are wanted, and the stools remaining undisturbed, they will send up a fresh supply of shoots for another year's service, and after these another; and in that manner they will furnish a succession for many years, observing to take up the crops of each year as above directed.

But I would observe, that after the first and second year, the stools spread at bottom, and send up many small shoots between, and in

C O C

in the rows; therefore, to encourage the principal shoots, all the small spawn should be annually drawn up in May and June.

It is likewise proper to remark, that although the stools of these roots will endure many years, they will in time become weak, or worn out, as also the soil; therefore, in six or seven years, more or less, when you perceive the shoots come weak and inconsiderable, prepare to make a fresh plantation in another part of the garden.

COCOS, Cocoa-Nut-tree.

There is but one species, an exotic tree for the hot house, of the palm tribe, having no branches, but very large, long, branch-like, winged leaves.

Class and order, *Monoecia Hexandria*.

Characters.] CALIX, male and female flowers apart on the same plant, growing in a spadix, protruded from a general univalvular spathe, each flower of the spadix having a cup composed of three small concave coloured leaves. COROLLA, each flower of the spadix composed of three petals. STAMINA, six filaments, and arrow-shaped antheræ. PISTILLUM, an oval germen, no style, but a trilobed stigma. PERICARPIUM, a very large, roundish, trigonous, leathery cover or drupe, inclosing a large, oval, hard nut, having three holes at the base.

The species is,

Cocos Nucifera.

Nut-bearing Cocos, or Cocoa-nut-tree.] Cocos with an upright, simple, branchless trunk, many feet high, garnished at top with large, branch-like, winged leaves, of many sword-shaped lobes, folded back at the edges; and at top of the stem, long spadiceous bunches of flowers, succeeded by clusters of very large, triangular, fibrous fruit, each containing a large oval nut, inclosing a white sweet kernel, and a quantity of wholesome milky liquor.

This tree is a native of India, where it obtains sixty feet stature; and its branch-like leaves are often twelve or fifteen feet long, appearing like branches, there being no other.

It is retained here in our stoves as a curiosity, its large leaves effecting a singular appearance.

It is raised from the nuts, great quantities of which are annually brought to England by the West-India ships; these, as soon as they arrive, are to be planted separately in pots of rich earth, placing them side-ways, and directly plunge the pots over their rims in a bark-bed, and in six weeks they will germi-

C O F

nate at the holes at the base, and will soon come up, giving frequent waterings, and continue them always in the stove, shifting them annually into larger pots, being careful at each removal to preserve the ball of earth about their roots, and not to break the fibres.

COFFEA, Coffee-tree.

It consists of one beautiful evergreen shrub for the hot-house, producing both flowers and fruit in England; and its fruit or berries is the Coffee.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is small, four-parted, and placed on the germen. COROLLA is monopetalous, funnel-shaped, tubular below, plane and five parted at top. STAMINA, five filaments placed in the tube of the corolla, and linear incumbent antheræ. PISTILLUM, a roundish germen, single style, and two thick reflexed stigmas. PERICARPIUM, an oval umbilicated berry, having two hemispherical seeds.

The species is,

COFFEA Arabica.

Arabian Coffee-tree.] Coffea with an upright brown stem, branching by pairs opposite, ten or twelve feet high, each pair crossing that immediately below it, and diminishing in length upward, garnished with large oblong-oval, waved, opposite leaves; and at the sides of the branches, close-fitting clusters of pure white quinquefid flowers, succeeded by oval berries, ripening to a blackish colour.

This is a very ornamental evergreen shrub, a native of Arabia Felix and Æthiopia, and requires the temperature of a hot-house in this country; so must always remain in pots of rich light earth, and reside constantly in that department, where it will continue its verdure beautifully the year round, produce flowers and ripe berries, and effect an ornamental appearance at all seasons, but more particularly in autumn and winter, when furnished with fruit.

It is raised from seed, i. e. the berries; and those produced here in our stoves will grow; observing, that as they soon lose their germinative property, it is eligible to sow them as soon as possible after they ripen. Let them be sown in pots of light rich earth half an inch deep, and plunge the pots in the bark-bed, giving light sprinklings of water once a week, and in about a month the plants will appear, which, when three inches high, prick into separate small pots, give a little water, and plunge them again in the bark-bed, and

and afford them shade from the sun till they have taken root, repeating the waterings moderately as you shall see occasion, and give them air in common with the other exotics of the same department.

This tree is also sometimes propagated by layers and cuttings, which, however, emit roots rather reluctantly; but it is worth the trial, planting them in pots of good earth, and plunge them in the bark bed, supplying them duly with water and occasional shade.

The general culture of this tree in this country is—it must remain continually in the stove, have water two or three times a week in summer, and about once a week in winter, and fresh air admitted in common with the other exotics of the hot-house; and as it advances in growth, allow it larger pots in proportion. Likewise, every year or two shift it into fresh earth, observing, at each time of removal, to trim off all matted roots on the outside of the ball, as also part of the old earth; then, placing the plant in the pot, fill it up with fresh compost, none better than good light kitchen garden earth, and directly give water, and plunge them in the bark-bed.

Cleanliness is also essential in the culture of this shrub here in our stoves; therefore, when it has contracted much dust or filth, let all the branches and leaves be well washed.

Likewise observe, that as it is frequently attacked by insects, particular attention is necessary when these appear, to wash and clean every branch and leaf one by one, which should be repeated as often as the vermin make their appearance; but if they are very numerous, it is a sign of ill health and weakness in the plant, and it proceeds chiefly from the root; therefore, in such a case, it is advisable also to shift the plant into entire fresh earth, and plunge it in the bark-bed; and when it recovers its health and vigour, the insects will disappear.

COLCHICUM, *Colchicum*, or Meadow-Saffron.

This genus furnishes a beautiful collection of bulbous-rooted, very low, flowery perennials for the borders, possessing the singular circumstance of their leaves appearing at one time, and their flowers at another; the former rising long and narrow from the root in spring, and decay in June; and the flowers, which are monopetalous, long, tubular, six-parted, and erect, rise naked; also from the root in autumn, not more than four or five inches high.

Class and order, *Hexandria Trigynia*.

Characters.] **CALIX** none. **COROLLA** is monopetalous, formed into a long tube, rising directly from the root, widening and divided above into six spear-shaped, oval, concave, erect segments. **STAMINA**, six awl-shaped filaments, and oblong, incumbent, quadri-valvular antheræ. **PISTILLUM**, a germen buried in the root, three long slender styles, and reflexed channelled stigmas. **PERICARPium**, a trilobate, trilocular capsule, having many roundish seeds.

The species are,

COLCHICUM Autumnale.

Common Autumnal Meadow Colchicum.] **Colchicum** with an oblong-roundish, dark-brown, bulbous root; erect plane leaves six inches long, and one or two broad; and flowers arising without foot-stalks directly from the root, having an erect tube three or four inches in length, widening above, and divided into six oval segments, in colour different in different varieties.

Varieties are] **Common Autumnal Colchicum** with single purple flowers—double purple flowers—many-flowered purple—variegated purple—with white single and double flowers—many-flowered white—white and red flowers—rose-coloured single and double flowers—variegated rose-coloured flowers—red flowers—red and white flowers—yellow flowers—with broad leaves—striped leaves.

²**COLCHICUM Montanum.**

Mountain Spanish Colchicum.] **Colchicum** with an oblong, roundish, very dark coloured, bulbous root; long, narrow, spreading leaves; and reddish flowers, rising without foot-stalks directly from the root, having a long tube divided into six narrow segments, and yellow stamina.

Variety.] **Mountain Colchicum** with striped red flowers.

³**COLCHICUM Variegatum.**

Variegated Chequered Eastern Colchicum.] **Colchicum** with an oblong, flattish, bulbous root; broad, waved, spreading leaves; and large flowers, rising without foot-stalks directly from the root, divided into six long erect segments, beautifully chequered with red, white, and crimson.

Varieties.] **Variegated chequered Colchicum** with double flowers—with plane leaves, and single and double chequered flowers.

The first of these three species, *Colchicum Autumnale*, in its single purple state, grows wild in many of our rich meadows; but which,

which, and all its varieties, being singularly ornamental, is also common in many curious gardens.

All the species and respective varieties are hardy, and are pretty autumnal ornaments for the fronts of flower borders; their nature of growth is, they produce their leaves commonly in spring, though those of the second sort often rise the beginning of winter, and those of all the sorts continue their growth till June, then totally decay, and the root in a manner remains dormant till August or September, when the flowers burst forth from it entirely naked, without foot-stalk, calix, or foliage, each flower consisting of one leaf, formed into a long erect tube, from three to five or six inches long, standing on the root, and divided at top into six oval erect segments; the lower tubular part supply the place of a foot-stalk to the upper divisions, and when the flowers fade, the seed vessels form within the ground, and slowly raise themselves among the green leaves the following spring, and the seeds ripen in May or June.

These plants may either be planted in beds by themselves, in rows nine inches asunder, or may be dispersed in the fronts of the different borders; observing, in either method, they should be planted three inches deep: and the season either for procuring roots to plant, or to transplant those already in your possession, from one part of the garden to another, or into fresh beds, &c. is when their leaves decay in summer; and the best time is from the beginning or middle of June until the beginning of August, after which time they will soon emit new fibres, and should not be removed, nor those already up be kept longer out of ground, if you would have them flower in perfection the same autumn.

They should be removed every two or three years at least, when the bulbs will be encreased into large bunches, so should be taken up and separated. See BULBOUS-ROOTS.

Most of these bulbs are so hardy, that they will flower as they accidentally lie out of ground; but this greatly weakens them.

Propagation.

Their propagation is by off-sets of the bulbs, of which they are very prolific, which are to be taken up and divided at the decay of the leaf in summer, as above hinted, planting the whole again before the middle of August.

New varieties are also obtained from seed, which should be sown in boxes, or large pots, in autumn, covering it a quarter of an inch

deep, and place them in a warm situation till spring, when the plants will appear, which should have only the morning sun during summer, giving water in dry weather; and in the second summer, when their leaves decay, plant them out in beds to flower.

COLUTEA, Bladder-Sena.

It furnishes hardy deciduous flowering shrubs, and a shrubby flowery perennial, all of them adorned with winged leaves of many pair of lobes, and butterfly-shaped flowers growing in clusters, and are elegant furniture for the shrubbery.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX is monophyllous, bell-shaped, five-parted at top, and permanent. COROLLA is papilionaceous, varying in figure in different species. STAMINA, ten filaments, one of them separating from the rest, and simple antheræ. PISTILLUM, an oblong compressed germen, a rising style, and a linear bearded stigma. PERICARPIUM, a large swollen bladder-shaped unilocular pod, having kidney-shaped seeds.

The botanists allow of but two or three distinct species, but of which there are some curious varieties.

The species of our gardens are,

COLUTEA Arborescens.

Tree Colutea, or Common Bladder-Sena.] Colutea with an upright, woody, whitish stem, branching laterally, and divided upward into a branchy head twelve or fourteen feet high, garnished with winged leaves of four or five pair of oval-obcordated lobes, terminated by an odd one; and from the sides of the branches, numerous small clusters of pale yellow flowers, succeeded by large bladder-shaped pods.

Varieties of this are the two following.

Pocock's Tree Colutea.] Colutea with an upright, woody, whitish stem, branching six or seven feet high; winged leaves, of several pair of oval-obcordated lobes, terminated by an odd one; and deep yellow flowers.

Oriental Tree Colutea.] Colutea with a woody stem, branching six or seven feet high; winged leaves of several pair of oval-obcordated lobes, ending in an odd one; and blood-coloured yellow-spotted flowers.

COLUTEA Frutescens.

Shrubby Ethiopian Scarlet Colutea.] Colutea with a shrubby stem, branching from the sides erectly four or five feet high; winged leaves of ten or twelve pair of oblong-oval, hoary, whitish lobes, terminated by an odd one;

one; and at the upper part of the branches, many small bunches of scarlet flowers, succeeded by large swollen pods.

The flowers of all the sorts are of the pea-bloom, or butterfly kind, consisting each of a standard, two wings, and a keel. See *PAPILIONACEA*.

They are all hardy enough to succeed in the shrubbery, but the second species requires a warm situation; they flower abundantly in June and July, succeeded by numerous pods, furnished with ripe seeds, from which all the sorts may be raised plentifully in the common ground.

The first sort and its two varieties are very ornamental, both in their beautiful pinnated foliage, and their numerous flowers, in June and July, as well as their bladder-shaped pods an inch or two long, which produce an agreeable variety in autumn; all of which are proper ornaments for any of the shrubbery plantations, as they prosper freely in any common soil and exposure, in common with other hardy flowering shrubs.

The second species is a most elegant plant, and flowers beautifully in June and July, but is rather of tender quality, being impatient of severe frost; so should have a sheltered sunny situation, and dry warm soil, and is proper also to retain some in pots, to move to shelter of a green house, or deep frame, in winter; observing, as the plants, at any rate, are apt to go off in two, three, or four years, a supply should be raised every year or two from seed, which when sown early in spring, the plants often flower the same year in August and September.

Propagation of all the Sorts.

The first sort and varieties are raised abundantly from seed, sown in February or March half an inch deep in a bed of common earth, and the plants will rise freely, and be fit to transplant in nursery rows in spring following, and in two or three years will be ready for the shrubbery.

They also grow by layers, layed any time in autumn, winter, or spring.

The second species, *Colutea Frutescens*, is also raised from seed, sown half an inch deep in a warm border in March or April, and when the plants are three inches high, transplant them, some in a sheltered border, and some in pots, to move under shelter the following winter. But if you would have the plants forwarder, or to flower the same year,

sow the seed in pots, and plunge them in a hot-bed early in March, it will forward them considerably, that the plants will probably flower in July or August.

COMPOSITUS Flos, Compound Flower, i. e. composed of numerous flosculi, or small florets in the same calix, as in daisy and sunflower.

All Compound Flowers are aggregate. See *AGGREGATUS*.

A compound flower is defined to be formed of an aggregate, or union, of several distinct fructifications, or many small florets, or lesser flowers, within one common cup or calix, and each floret furnished with a proper fructification, either all hermaphrodites, or males and females, or hermaphrodites or males in the disc or middle, and females in the radius or circumference, and all the hermaphrodites having each five stamina, and these always united by their antheræ or tops into a cylinder, through which passes the style, crowned by divided stigma, having both the divisions or segments revolute, or rolled back, and each floret succeeded by a single naked seed, which is either coronated with down, &c. as in dandelion; or the crown is wanting, as in sunflower.

Examples of Compound Flowers, are daisy, feverfew, marigold, sunflower, aster, chrysanthemum, hawk-weed, centaury, African marigold, dandelion, and many others; all of which are formed of many florets in one common cup, as above described.

All Compound Flowers, which are a numerous tribe, are of the class *Syngenesia*. See *CLASSIS*.

The other general properties of a Compound Flower are,

The common or general calix is formed either of one series of leaves, immediately surrounding the receptacle and floscules or florets, or of a double series, frequently a lesser and a greater, and is sometimes imbricated, i. e. formed of many scales.

The lesser flowers or florets that form the Compound Flower are universally monopetalous, i. e. of one petal, sitting close upon the receptacle, and are of different figures and sizes in different genera; and under each floret is generally placed a single seed.

The compound flowers have different appellations, according to the form, or figure, and situation of the florets of which it is composed.

They

They are generally distinguished by the following appellations.

Tubular Compound Flower, (*tubulosus*, or of hollow florets); all the florets that compose the flower are tubular and funnel-shaped, that is, hollow almost from bottom to top, and divided into five spreading parts at the brim, and which kind of florets, when they compose entirely the whole Compound Flowers, are mostly all hermaphrodites, having each five stamina and a style; though there are tubular male and female florets, common to some genera; also hollow neutral florets.

Ligulated Compound Flower, (*ligulatus*, flat or strap-shaped florets); the florets that compose the flower are all plane, flat, and expanded, and resemble a strap, fillet, or tongue, and are either entire at top, or divided into three or five parts, and which kind of florets, when they form entirely any compound flower, are commonly all hermaphrodites, and have each its five stamina, style, and naked seed, as in hawkweed, dandelion, and many other genera; but there are also ligulate male and female florets, sometimes in the same or different flowers.

Radiated Compound Flower, (*radiatus* or *radius*, a radiated margin or circumference); having one, two, or more series of long flat florets placed round the margin or outward part, in form of a ray, or resembling the rays proceeding from the body of the sun, as in sunflower; and the disc (*discus*), or central part, is formed by numerous small tubular florets, exemplified also in sunflower, marigold, &c. In most radiated compound flowers, the radius is generally formed of ligulated or plane florets, as in sunflower and marigold just mentioned, and are commonly all females or neutrals; and the tubular florets in the disc are generally all hermaphrodites or males; but in some genera the radius is formed by long tubular florets, unlike those in the centre, as in centaury or blue bottle; and in some the florets in the radius are naked, that is, without petals altogether.

It is mostly to be observed, that both tubular and flat florets, in all Compound Flowers that are not radiated, are generally all hermaphrodite.

And in radiated Compound Flowers, the florets which occupy or form the disc, are, for the general part, all hermaphrodite or male; and the semi, or other florets, that constitute the rays, are most commonly females or neutrals.

Neutral florets are such as want both stamina and style, and are of no sex, or neuter.

Naked florets are such that have no petal or corolla.

But Compound Flowers are constituted several ways, as,

Tubular hermaphrodite florets, both in the disc and radius.

Tubular hermaphrodite florets in the disc, and tubular females in the radius.

Tubular hermaphrodites in the disc, and tubular neutrals in the ray.

Tubular hermaphrodites in the disc, and ligulate hermaphrodites in the radius.

Tubular hermaphrodites in the disc, and ligulated females in the radius.

Tubular hermaphrodites in the disc, and ligulated neutrals in the ray.

Tubular hermaphrodites in the disc, and naked females in the radius.

Tubular male florets in the disc, and naked females in the rays.

Ligulated hermaphrodites both in the disc and radius.

As to the number of florets in a Compound Flower, they are generally very numerous and indeterminate.

In some genera the florets of the Compound Flower have small distinct cups within the larger, and belong to the fifth order of the class *Syngenesia*.

Of Double Compound Flowers.

Plenitude or doubleness in Compound Flowers is effected different ways.

As, for example, radiated Compound Flowers, which generally have plane florets in the margin, and tubulars in the disc, is rendered double two different ways; that is, the plenitude may either be effected by an increase of the radius, and an almost total exclusion of the tubular florets in the disc, or is effected by an elongation of the hollow florets in the centre, and a less profound division of their brims. In the first mode of impletion, which is termed impletion by the radius, it is evident that a radiated flower, rendered double by the radius, will be either almost entirely female florets, as in feverfew and African marigold; or of neutral florets, as in sunflower: and in the second mode of impletion, termed impletion by the disc, the florets of that part are extended to a great length, and those of the radius, though they sometimes remain unchanged, most commonly adopt the figure of those of the disc, without, however,

ever, suffering any alteration in the point of sex; daisy, feverfew, and African marigold, exhibit instances of this, as well as the former mode of impletion.

The impletion of tubular Compound Flowers seem to observe the same rule as that of the radiated flowers just delivered.

COMPOSTS. In gardening, Composts are compounds or mixtures of several earths, or earthy substances, and dungs, either for the improvement of the general soil of a garden, or of that for some particular plants.

Almost every plant in nature may be said to have some particular favourite soil, and yet there is hardly any plant or tree but what will prosper in common garden earth; and even the most delicate plants of our green-houses, stoves, and hot-beds, are found to succeed in common rich light mould, of the quality of that of a good kitchen garden; so that none need be at any great loss on the consideration of Composts. I would observe, however, that many kinds of plants may be farther improved by Composts adapted to the soil of their natural growth; but, on the other hand, would be understood to mean, that only a few different Composts is necessary for all the known plants in the world, which we can affirm for the satisfaction of the unexperienced, and not perplex them with tedious directions in every genus, for preparing expensive and troublesome Composts for every species thereof, which is altogether unnecessary.

But there are some authors on gardening particularly profuse and tedious in the article of Composts, frequently prescribing a different one for almost every different plant, which too, are often of so strange composition, and seem loaded with such inconveniences, trouble, and expence, in their preparation, as is sufficient to dishearten the unexperienced from attempting any thing in the vegetable world; as, for example, in Hill's works we may see directions for two or three hundred different Composts, and, as just observed, most of them too of such uncommon composition, of so many different strange ingredients, as to be considerably beyond the limits of general practice; nor would there be any end of the trouble and expence, which, after all, would be unnecessary, and of no more service to the plants than they might receive from a few well-prepared Composts of more practicable structure, or even from common garden earth.

I therefore have found such a multiplicity

of composition entirely unnecessary and perplexing, because it is well known to observant practitioners, that a soil proper for every plant may be imitated in three or four principal Composts.

As, for instance, a rich moderately light Compost, of the texture of kitchen-garden earth, is agreeable to most plants. A loose light Compost for some particular plants; a dry, sandy, rubbishy, Compost for others, such as most of the succulent tribe; and a loamy fattish Compost, of a pliable mouldery temperature, is particularly well adapted to most sorts of trees and shrubs, and indeed to most plants that are not succulent.

But prepared Composts are principally in practice for plants in pots, and for some curious flowers in beds, and tender plants in hot-beds, &c.

In respect, however, to Composts, for the amendment of the general soils of a garden, several species of earthy substances may be employed, according as the quality of natural soil shall require; as, for instance, if the natural soil is of a very light, loose, or sandy quality, it may be assisted occasionally by the addition of heavy substances, such as loam, and any kind of fattish earth, mud of ponds and ditches, with plenty of rotten dung; on the other hand, heavy, clayey, and all stubborn soils, may be meliorated by light Composts, i. e. any light sandy earth, drift and sea-sand, the shovellings of turnpike-roads, the cleansing of streets, all kinds of ashes, rotten tanner's bark, rotten wood and saw dust, and other similar light opening materials that can be most conveniently obtained, adding to any, or all of them, a convenient portion of dung.

As to Composts for particular curious plants, to be preserved in pots or tubs, beds, &c. the following are in practice.

One principal Compost in practice is, fresh or maiden earth from a pasture-ground, that is, of a light, but fattish mouldery temperature, and if it inclines to loam of a pliable texture, it will be an advantage; however, of any fat pliable pasture earth, take the top spit turf and all, and to which add about one third or fourth part of thoroughly rotten dung, and lay the whole in a long heap or ridge a yard high, in a situation exposed to the sun and air, to lie a year, turning it over several times, that the whole may be converted to mould, and the parts properly incorporated; and this will be found to answer almost every purpose.

purpose of vegetation. But in default of good pasture earth, which is sometimes inconvenient to be obtained, a quantity of good garden mould, of the above quality will answer very well; but more particularly that which has been well cultivated by proper manure, which may at all times be procured from the quarters of the kitchen garden: add thereto one third or fourth part of rotten dung, none better than that of old hot-beds; and if the mould is rather of a stiff nature, add also about a fourth part of sea, or drift sand, or, for want of these, ashes, or rotten tan, &c. casting the whole in an heap, to lie five or six months, but if a year the better, stirring it over several times, as above directed.

Another Compost in use is, that for plants that particularly require a more light loose soil; a Compost may be formed of one half good light pasture mould, or that of a garden, and about one third part of sand, and another of rotten dung, forming the whole in a heap as above.

For plants that require a soft loose rich earth, use for Compost good light rich earth of a garden or pasture, rotten tanner's bark, or rotten earthy wood, saw-dust, tree leaves, rotten dung, and a small portion of sand.

For plants that delight in dry rubbishy soils, as the succulent tribe, form a Compost of one half of perfectly light garden or pasture mould, and one half of sand or road soil, and a little screened lime rubbish, laying the whole in a heap for a year, and turn it four or five times; which Compost may be made lighter or heavier, according as the plants are more or less succulent.

A loamy Compost, as already hinted, is a favourite soil of numbers of plants; that is, though most plants will flourish in any kind of good earth, or the Composts before-mentioned, yet that of a light, warm, loamy temperature, is found to improve the culture of almost all sorts of plants, but more particularly all the tree and shrub kind: this Compost is thus prepared; maiden or fresh loamy earth from a common, or any dry pasture-ground, where the soil is of a soft and moderately light pliable nature (see LOAM), taking the uppermost spit, sward and all, chopping it to bits, and add thereto rotten dung, as before directed, which, after lying in a ridge or heap twelve or fifteen months to rot the sward, and by frequent turnings over to break the clumps, and mix the parts, will be excellent for use; when, if necessary, it may either be made lighter by the addition of some of the

fore-mentioned light materials, or made heavier by a mixture of fat garden earth, according as the nature of particular plants shall require, which will be always hinted in the culture of the respective articles, whether in pots, beds, or borders.

The florists are generally curious in their compositions for their fine prize flowers; the following are their auricula and hyacinth Composts, but which will also answer for almost all other curious flowers.

For auriculas, the favourite Compost is, light earth from a pasture ground, the top spit with the sward, and neats dung, of each an equal portion, and about half the quantity of drift or sea-sand, and, when it can be had, a little rotten willow earth, or any rotten earthy wood, or old rotten tan or saw-dust, forming the whole in an heap for a year, turning it over several times at proper intervals.

This Compost is also proper for many other curious flower plants, such as the fine carnations, curious ranunculas, and anemonies; and for which, to make it go farther, you may add a quantity of good garden mould; observing, however, that though these flowers often excel in the above Compost, yet I have observed them flower almost equally well in common rich light garden earth.

For the hyacinth, the favourite Compost is different from the above, though that will answer tolerably well, as will also some of the other light Composts, and they even often prosper well in good garden earth; however, curious florists, to blow that delightful flower in its highest perfection, often use the following Compost—Neats dung and drift sand, of each an equal portion, and half the quantity of old rotten tan, and where it can be easily procured, the same portion of rotten leaves of trees, or, in lieu thereof, add a little more rotten bark, and a little very light earth from a pasture or garden; let the whole be mixed in a heap, to lie at least a year, giving it frequent turnings; but if it remains in the heap eighteen months, or two years, it will be an advantage.

Of one or other of all the above Composts you suit all sorts of plants sufficiently, of which directions are given in the culture of all the respective articles; and any of the sorts of Compost may always, upon occasion, be eked out by an addition of garden earth, in proportion to the intended temperature of each respective Compost.

But where any particular Compost is necessary,

COM

cessary, it is exhibited in treating of the culture of the respective articles.

In all Composts where sand is necessary, sea or drift-sand is to be preferred, and that which is dug out of pits is the most improper of all; therefore, where sea-sand cannot be easily obtained, which is rather the best, always chuse drift-sand, or that taken near the surface.

Likewise in Composts where rotten earthy wood is requisite, that of old rotten willow trees, or any other that can be had, will do; or, in default thereof, old rotten tanner's bark may be substituted, and is a very proper ingredient; also all sorts of wood saw-dust may be used.

In using garden mould occasionally for compositions, the places of the quarters from whence it is taken, may readily be made good by a due supply of manure, and the emptyings of pots of old earth, and old flower-beds, &c. which being wrought up together with the natural soil, will be excellent for the growth of kitchen vegetables.

All Composts should be formed in an open exposure, free to the sun, air, rains, frosts, &c. to meliorate and fertilize the soils; and the ingredients should be formed in an heap, not in a large and high one, but rather extended in length like a ridge, about a yard or four feet thick, so that the rays of the sun may penetrate through it: once every two or three months, at least, it ought to be turned over, and the bottom thrown to the top, that all the parts may be well mixed, and equally participate of the influence of the sun and elements; this is so essential, that if the heap is not thus exposed, the Compost would be far from effecting the proposed advantage to the plants, and would to many sorts rather prove detrimental, that it would be more eligible to use common garden mould immediately from a well-cultivated border or quarter.

It is necessary that all Composts for plants in pots, tubs, &c. also for all tender plants in hot-beds and flower-beds, should remain a year in the heap or ridge before it is used, especially those Composts formed of fresh earth and other new materials, which should always have a summer's sun and winter's frost, and frequent stirring, for the whole should be perfectly meliorated, and converted to a pure mould.

When the Composts are to be used, it is not adviseable to screen them, except for some particular purposes, which are hinted in dif-

CON

ferent parts of the work; so that, for general uses, the soil should only be broken fine with the spade and hands, for, when fine screened or sifted, it becomes too compact for the roots of plants.

The term *maiden* or *virgin* earth, often mentioned for Composts, signifies that of any common, or other pasture ground, that have never been ploughed for the production of other crops, or, at least, that have been a long time in pasture.

CONIFERÆ, Coniferous, or Cone bearing; plants which bear that kind of fruit or seed-vessel, called a Cone. See CONUS and STROBILUS.

The plants of this tribe are mostly of the tree and shrub kind, and retain their leaves all the year, except some sorts of larch, which lose their leaves during the winter.

The principal genera of the Coniferous tribe are, the *pinus*, or pine-tree, including fir, larch, and cedar of Lebanon—the *cupressus*, cypress-tree—*Thuja*, arbor-vitæ—*ephedra*, shrubby horse-tail—*juniperus*, juniper-tree, including savin, and several species of cedars. The height of some species of *juniperus* do not exceed two feet, that of some species of *pinus* approach to a hundred; their form is generally conical, and extremely beautiful, from the disposition of their branches, which surround and cover the stem even to the root, and extend themselves horizontally and circularly, like so many rays.

Most of the Coniferous trees are resinous, or gummy; these gums have a bitter taste, but very agreeable smell, and it is said, plantations of them are exceeding wholesome, by meliorating the air by their balsamic and aromatic exhalations, besides being beautiful to behold.

From the larch-tree is extracted what we erroneously call Venice turpentine; from the wild pine, or pineaster, is extracted the common turpentine, and from which is distilled the oil of that name; the dregs of the distillation is the common rosin: the pitch-tree, a sort of fir, produces the substance from whence it derives the name. The branches of the black and white spruce-firs are used by the Americans in making their spruce-beer; the leaves of the common savin are used by farriers for destroying worms in horses. A decoction in milk of the seeds of pineaster, or of the extremities of the branches pulled in spring, is said, with a proper regimen, to cure the most confirmed and inveterate scurvy.

All

All the sorts are hardy and valuable plants in ornamental gardening, and many of them most valuable timber trees, particularly the genus *pinus*; none are more ornamental when growing, or turn to more profit when felled, for they arrive to great height and magnitude, and, as timber, are superior for most kinds of buildings, and most excellent for masts of ships.

The timber of the horizontal cypress is said to resist worms, moths, and all putrefaction, and to last many centuries; the doors of St. Peter's church at Rome were originally of this material, which, after lasting eleven hundred years, discovered not the least tendency to corruption.

But for the culture, and other particulars of the Coniferous trees, see their respective genera.

CONVALLARIA, Conval Lily, or Lily of the Valley, and Solomon's-Seal.

This genus consists of hardy, herbaceous, flowery perennials, producing annual stalks from six inches to a yard in stature, adorned with oblong ribbed leaves, and monopetalous, small, bell-shaped flowers, and are eligible furniture for the pleasure-ground.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, monopetalous, bell-shaped, six-parted, and spreading at the brim. STAMINA, six filaments inserted into the corolla, and erect antheræ. PISTILLUM, a globular germen, slender style, and obtuse trigonous stigma. PERICARPIUM, a round trilocular berry, and single seed.

The species of our gardens are,

¹CONVALLARIA *Majalis*.

Lily of the Valley, or May Lily.] Convallaria with a fibrous creeping white root, crowned by oblong, erect, longitudinally-veined leaves, in pairs, five or six inches long, and one or two broad, and among them naked flower-stalks half a foot high, garnished with drooping white flowers, ranged in a single series on one side the stalk.

Varieties.] Lily of the Valley with single white flowers—double white flowers—red flowers—purple and white striped flowers—double purple and white flowers.

This species and varieties grow naturally in woods and shady places, in many parts of Britain, and other parts of Europe; but all of them possess great merit as flower-plants for shady borders, and the compartments of wilderness works, and the like, though they

will succeed any where; and those of the double and striped kinds, particularly, are very beautiful.

²CONVALLARIA *Polygonatum*.

Polygonatum, or Common Solomon's-Seal.] Convallaria with a thick, knotty, fleshy, fibrated, white root; upright, two-edged, firm stalks, two feet high, garnished with oblong-oval, ribbed, alternate leaves, their base embracing the stalk; and from their axillas, short divided foot-stalks, each supporting one drooping white flower.

Varieties.] Common Solomon's-Seal with single white flowers—double white flowers—sweet scented white flowers—with purple stalks and white flowers.

This and varieties, as well as an ornamental plant in gardens, are of medical property, and its root is the part chiefly used, being frequently applied as a poultice to green wounds and bruises, and a decoction of the plant cures the itch.

³CONVALLARIA *Multiflora*.

Multiflorous Solomon's-Seal.] Convallaria with a thick, jointed, fibrated, white root; upright taper stalks near a yard high, garnished with broad, oblong-oval, alternate leaves, embracing the stalks with their base; and from their axillas, short foot-stalks, supporting many greenish-white flowers.

Varieties.] Large Broad-leaved Multiflorous Solomon's-Seal with single and double flowers—Dwarf Multiflorous Solomon's-Seal with striped leaves.

⁴CONVALLARIA *Racemosa*.

Racemous-flowered Solomon's-Seal.] Convallaria with a thick, knotty, fibrated root; upright stalks two feet high; oblong, pointed, ribbed, close-fitting, alternate leaves; and the stalks terminated by racemous spikes of greenish-white flowers.

⁵CONVALLARIA *Verticillata*.

Verticillated Narrow-leaved Solomon's-Seal.] Convallaria with a thick, jointed, fibrated, white root; upright angular stalks two feet high; long, narrow, smooth leaves, in a verticillus or whirl round the stalks; and from the places of the leaves, short foot-stalks, each supporting four or five small whitish flowers.

The flowers of all these species are monopetalous, bell, or funnel-shaped, rather small, and divided at the brim into six spreading segments, appearing in May and June, succeeded by round berries, furnished with ripe seeds in autumn.

They are all perennial in root, but the stalks and

and leaves are annual, rising in spring, and perish in autumn.

All the sorts are hardy, and delight in shady places, so are well calculated as ornamental furniture for the borders of wood-walks, wilderness-quarters, and shady borders, where they will appear very ornamental both in their singular growth, foliage, and flowers, but all the sorts will also grow in almost any situation, and multiply exceedingly by their creeping roots; and all the culture they require is, to have the ground dug between them annually, in common with the other plants, and to cut down their decayed stalks, and every three or four years to reduce their roots within due compass.

Propagation.

The propagation of all the sorts is effected abundantly by dividing or slipping their roots any time from autumn till spring, though those divided and planted out in autumn will flower strong the following summer; the slips may be planted at once where they are always to remain, and they need not be removed oftener than every three or four years, when, if they are greatly encreased, it is proper to reduce them within due bounds.

CONVOLVULUS, *Convolvulus*, Bind-weed, or Bear-bind.

This genus comprises many herbaceous twining and trailing plants, annuals and perennials, of which there are some of very flowery growth, and proper ornaments for the pleasure-ground, and one or two for the green-house, all of them adorned principally with spear and heart-shaped leaves, and large open bell-shaped flowers.

This genus derives the name, *Convolvulus*, from *convolvendo*, i. e. rolling round, or twining about, as most of the plants wind and ascend spirally round any support.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is monophyllous, oval, five-parted at top, and permanent. **COROLLA** is monopetalous, large, bell-shaped, and spreading. **STAMINA**, five short filaments, and compressed antheræ. **PISTILLUM**, a roundish germen, slender style, and two broad oblong stigmas. **PERICARPIUM**, a roundish capsule, having several roundish seeds.

There are upwards of thirty species, but not a quarter of them have merit in gardening, and some are common and very troublesome weeds, such as the Trailing Field Bind-weed, and the Large Volubilate White Bear-

bind, both of which are species of *Convolvulus*; the latter, in particular, is often very troublesome in gardens in summer, by its winding stalks, which twine about any thing they encounter, either along the surface of the earth, or ascend spirally about tall plants or trees ten or fifteen feet high.

The species of this genus, therefore, that merit culture, are principally for ornamental purposes; and the following are the most material species of our gardens.

The first three are hardy herbaceous annuals.

¹**CONVOLVULUS** *Tricolor*.

Tricolor Convolvulus, commonly called *Convolvulus Minor*.] *Convolvulus* with prostrate branchy stalks two feet long, trailing on the ground, garnished with spear-shaped-oval, close-fitting leaves; and at their axillas, long foot-stalks, each supporting one large, tricoloured flower, blue, having a white and yellow flower.

Varieties.] *Convolvulus Minor* with blue flowers, having white bottoms—with white flowers—variegated blue and white flowers.

This species and varieties are very floriferous annuals; the stalks generally prostrate themselves along the ground, without any twining or climbing property, spreading their branches every way, flowering at every joint from June till September.

²**CONVOLVULUS** *Purpurea*.

Purple Convolvulus Major.] *Convolvulus* with twining, spirally ascending stalks and branches, winding about support six or eight feet high, adorned with roundish, heart-formed, entire leaves; and from the sides, erect foot-stalks, supporting large open purple-coloured flowers.

Varieties.] *Convolvulus Major* with deep purple flowers—red flowers—blue flowers—white flowers.

These varieties are very flowery and beautiful annuals, and if their stalks have support to climb upon, they will flower at every joint from July till October, succeeded by abundance of ripe seed.

³**CONVOLVULUS** *Nil*.

Anil, or Deep Blue Convolvulus Major.] *Convolvulus* with twining stalks and branches, mounting about support six or eight feet high, garnished with heart-shaped, three-lobed, hairy leaves, and long axillary foot-stalks, each supporting two large deep blue flowers.

This is an exceeding beautiful annual, requires support to climb upon, and will exhibit a fine bloom from August till October.

The

The two following are shrubby perennials of the green-house.

⁴CONVOLVULUS *Canariensis*.

Canary Evergreen Convolvulus.] Convolvulus with twining, woody, perennial stalks and branches, winding about support twenty feet high, garnished with heart-shaped-oblong, downy, evergreen leaves, and axillary foot-stalks, each supporting several purplish flowers.

⁵CONVOLVULUS *Cneorum*.

Cneorum Album, or Silvery Convolvulus.] Convolvulus with upright, shrubby, perennial stalks, branchy, and a yard high, closely garnished on every side with spear-shaped, downy, silvery leaves; and at the ends of the branches, clustery heads of reddish flowers.

The flowers of all these species are monopetalous, bell-shaped, large, and spreading, appearing in June, July, August, and September, are very elegant; and although each flower is but of one day's duration, the annual sorts exhibit a daily and plentiful succession till killed by the frost, and ripen abundance of seeds.

They are all natives of distant countries, but have long been inhabitants of our gardens as plants of ornament.

All the annual kinds are hardy, and are beautiful furniture for the pleasure-ground; will prosper in any common soil, and are proper both for borders and the vacant spaces in the fronts of the most conspicuous shrubbery-clumps; and they all rise freely from seed in the full ground, which may be sown where they are to remain to flower; observing, that the *Convolvulus Tricolor*, or *Minor*, may either be suffered to trail upon the ground, according to its natural growth, or may be tied up to sticks: but the other two annual species, and their varieties, being of the voluble or twining running kind, must have tall sticks to climb upon, on which they will naturally twine themselves several feet high, flowering all the way, and appear very ornamental.

The propagation of all these annual kinds is by sowing the seed in March or April, in patches, in the places where they are to flower; in each patch sow four or five seeds half an inch deep, and when the plants are an inch or two high, thin them, leaving but two or three of the best in each patch, (see ANNUAL PLANTS) managing them afterwards as above directed.

The two perennial species are tender, but elegant furniture for the green-house collection, and well worth the attention of every one possessed of the conveniencies for preserving them during winter.

Let them be kept in pots of rich earth, and managed as *geraniums*, and *myrtles*, &c. See GREEN-HOUSE PLANTS.

The propagation of these two sorts here is commonly by layers in the spring, which take root freely in three or four months; cuttings of the young shoots also grow freely in a shady border in May, June, and July; suckers from the root also make good plants.

Of this genus, the two following perennials, Bindweed, and Bearbind, before hinted, are well-known troublesome weeds; but as they produce many elegant flowers, some for variety preserve here and there patches of them for flowering.

Their titles, &c. are,

⁶CONVOLVULUS *Arvensis*.

Field Perennial Convolvulus, or Bindweed.] Convolvulus with creeping and deeply penetrating, small, fibrey, tough roots; many weak trailing and twining stalks, two or three feet long, garnished with small, triangular, arrow-pointed leaves, the base pointed at both sides; and at all the joints, a single flower, on each foot-stalk, of different colours in different varieties.

Varieties.] Field Perennial Convolvulus with white flowers—rose-coloured flowers—rose and white striped flowers—white and purple flowers—white and purple striped flowers—purple white-rayed flowers.

All these varieties grow wild in great abundance on the sides of banks and dry gravelly soils, where they exhibit a profusion of flowers; but if some patches are intended for the garden by way of variety, great care is requisite to keep their roots within due compass, for they creep far, and their stalks over-run whatever they grow near, and often rise naturally in gardens, proving most troublesome weeds, difficult to eradicate, for the roots run deep, and are so very tough, that gardeners in wrath often call them the devil's guts.

The roots are perennial, and the stalks rise in spring, and die to the root in autumn.

⁷CONVOLVULUS *Sepium*.

Hedge Perennial Convolvulus, or Great White Bearbind.] Convolvulus with long, creeping, thick, fleshy, white roots, sending up annually many twining stalks, winding round support ten or fifteen feet high, garnished with large, roundish and oblong, arrow-pointed leaves, divided at the base; and long foot-stalks from the joints of the branches, each supporting one large, bell-shaped, pure white flower.

Varieties.] Large purple flowers—large purple-striped flowers.

This species grows wild in hedges and gardens, have perennial roots, and annual stalks, ascending spirally round the neighbouring plants, bushes, hedges, and trees, producing many fair flowers; but if some patches are designed as climbers in wilderness-works, or shrubberies, for variety, they should be placed detached from all other plants and trees, and fix long stout stakes for their stalks to twine upon, and keep their roots within due bounds, for they often rise naturally in gardens, and prove most troublesome weeds to the gardener, having very creeping roots, that multiply greatly, run deep in the ground, and the least bit will grow and send up stalks that overrun and twine round every thing in their progress; therefore, in digging the ground, every bit that appears should be carefully picked out, and in summer the stalks should be constantly pulled up, which will also contribute considerably to the destruction of the roots.

The following perennial of the same genus is also cultivated in some gardens for variety.

**CONVOLVULUS Batatas.*

Batatas, or Spanish-Potatoe.] *Convolvulus* with large, oblong, tuberous, white, eatable roots; trailing stalks three or four feet long; heart-shaped-angular leaves; and large, bell-shaped, white flowers; and the stalks rooting at the joints, and form large tubers.

This is a native of Spain and Portugal, where the roots grow very long and large, resembling large white kidney-potatoes; they do not, however, acquire perfection in England, but a few of the roots are annually imported from the above countries for curiosity, and we may often see them lying in the great fruiterer's shops in London.

If intended to have a few plants for variety, plant the roots, either whole or divided, in a warm border, in March or April, where they will send up stalks, and flower in autumn; but to have them in greater perfection, plant the roots in a slender hot-bed, covered with a frame and glasses during bad weather, by which aid they flower earlier, and often form many tubers at the joints.

CONUS, a Cone; a species of fruit, or scaly seed-vessel, of the coniferous trees, as the pine-tree, &c. formed into a conical figure, and commonly called a Cone, *Conus*; but modern botanists have substituted in its place *Strobilus*. See **STROBILUS**.

This species of seed-vessel is formed of an amentum, and composed of many hard woody

scales, curiously arranged, and fixed by their base to an axis, which occupies the middle of the Cone, so they open only at top: in many species of pine-tree, the scales of the Cone are of a bony nature, and almost united, as those of the cedar of Lebanon, Scotch pine, &c. in fir, larch, arbor-vitæ, and cypress, the scales are of a substance like hard leather; and in juniper, savin, &c. they are united, and become fleshy and succulent like a berry. These scales, which compose the Cones, serve, at first, each as a calix to a fructification, and being persistent, they harden by degrees to a bony or very hard substance, serving also as a sort of pericarpium to the seeds, which are lodged naked principally betwixt the bottom of the scales, and by them nourished as in a proper seed-vessel.

The scales of the Cones often so closely involve the seeds, that they cannot be dislodged without violence, by splitting the Cones open with an instrument driven through them, or till they are exposed to the midsummer sun, or before a fire, which causes them to open gradually. See **PINUS**.

The seeds themselves are mostly oblong, hard like a nut, and crowned with a large membranaceous wing.

These seeds or kernels, in some species of *pinus*, are eatable, particularly those of the *pinus pinea*, or stone-pine, being exceeding wholesome, and good for coughs and consumptions; and in Italy, where the trees abound, they are served up to table with other fruits in the desert, during the winter season.

CONYZA, Fleabane.

It consists of herbaceous and shrubby plants, adorned with compound flowers, and of which there is one small shrubby species, pretty common in our green-houses.

It is titled,

CONYZA Candida.

Shrubby White-leaved Conyza.] *Conyza* with a short shrubby stalk, branching six or eight inches high; closely garnished with oval, small, downy, white, silvery leaves; and from the sides and ends of the branches, long woolly flower-stalks, each sustaining two or three yellow compound flowers.

It requires shelter in winter, and is very beautiful in its low bushy growth and silvery leaves: let it be kept in pots of rich earth, to be moved to a green house or garden-frame, to have shelter from frost; and it may be propagated by slips of its branches in spring, which, if planted in pots, and plunged in

in a hot-bed about a month, and often watered, will grow freely; but cuttings planted in summer, often emit roots without the aid of a hot bed.

COREOPSIS, Tick-seeded Sunflower.

The plants are herbaceous very flowery perennials, proper for the pleasure-ground, obtaining from three to six or eight feet stature, terminated by clusters of compound radiated flowers.

Class and order, *Syngenesia Polygamia Frustanea*.

Characters.] **CALIX**, compound radiated flower, having a double general cup; the outer one is of eight small leaves, and the inner one is large and coloured. **COROLLA**, many hermaphrodite tubular florets form the disc, and eight large flat neutral ones the ray. **STAMINA**, five short filaments, and cylindric antheræ. **PISTILLUM**, a compressed germen, slender style, and bifid stigma; but no style nor stigma in the neutrals. **PERICARPIUM**, none. **SEMINA**, each hermaphrodite floret succeeds to an orbicular seed, bordered and horned at top.

The species of most note are the three following perennials.

¹**COREOPSIS Alternifolia.**

Alternate-leaved Virginia Coreopsis.] Coreopsis with upright strong stems seven or eight feet high, garnished on every side with spear-shaped, sawed, alternate leaves, having decurrent winged foot-stalks or borders, running from the base of one to the other, and the stems crowned by large, radiated, yellow flowers.

²**COREOPSIS Tripteris.**

Ternate-leaved American Coreopsis.] Coreopsis with upright, round, smooth stalks, six or seven feet high, garnished at each joint with trifoliate opposite leaves, and the stalks terminated by bunches of large flowers, having a yellow radius and purple disc.

³**COREOPSIS Verticillata.**

Verticillate Multifid-leaved Coreopsis.] Coreopsis with upright, angular, stiff stalks, three or four feet high, branching by pairs, adorned round the joints with compound-winged, finely-divided leaves; and from the sides of the branches, long foot-stalks, each supporting one flower, having a dark-purple middle, and bright-yellow ray.

These have all perennial fibrous roots, and annual stalks, which rise in spring, flower from July till October, and decay to the root in November.

The flowers are all compound, radiated, and pretty large, shaped like sunflowers, but smaller, and are very ornamental.

All three species are good furniture for the large compartments of the pleasure-ground, either for spacious borders, or the shrubbery plantations, introducing them in the vacant spaces between the shrubs, on the boundaries of lawns or principal walks, for all of them will exhibit a plentiful bloom from July or August, until prevented by frost.

Their propagation is easily effected by slipping or dividing the roots in autumn, when the stalks decay, planting the slips at once where they are to remain, and they will call for no farther trouble than keeping them clean from weeds, and to cut down the decayed stalks annually in autumn.

CORIANDRUM, Coriander.

It consists of herbaceous annual herbs of the culinary and medical tribe, and their leaves are the useful parts for the kitchen, and the seeds for medicine.

Class and order, *Pentandria Digynia*.

Characters.] **CALIX**, umbellate flowers, having a general involucre, scarce monophyllous, and the partial one of three leaves, and a small five-parted calix to each floret. **COROLLA**, a difform, radiated, general umbel, and the florets composed of five heart-shaped inflexed petals. **STAMINA**, five filaments, and roundish antheræ. **PISTILLUM**, a germen under each floret, two styles, and radiated stigmas. **PERICARPIUM**, none; a spherical two-parted fruit, and two hemispherical seeds.

There are but two species, both of which have divided small leaves, somewhat resembling parsley; but there is but one species generally cultivated.

The species are,

¹**CORIANDRUM Sativum.**

Cultivated Coriander.] Coriandrum with a small, fibrey, white root, crowned by many-parted leaves, having broadish segments; and in the centre an upright, round, branchy stalk, two feet high, having all the branches terminated by umbels of flowers, succeeded by globular fruit.

²**CORIANDRUM Testiculatum.**

Testiculated Smaller Coriander.] Coriandrum with smaller many-parted leaves, and upright, angular, slender, branchy stalks, terminated by umbels of flowers, succeeded by testiculated or twin fruit.

The first species is that commonly cultivated,

C O R

vated, which, as a garden-herb, is sometimes used both for culinary uses in soups, &c. and as an ingredient in fallads; but as the leaves are of a foetid smell, it is in no great esteem in England, except in some foreign families.

It is propagated by seed, which for garden use may be sowed any time in spring or summer, sowing it in shallow drills half an inch deep, and let the drills be six inches asunder, observing, as the plants soon fly up to seed, a repetition of five or six sowings is requisite from March till September; and the last sowing should be on a warm border, to stand the winter.

When this plant is to be cultivated for its seed, it should be sowed in March, either in drills a foot asunder, or by broad-cast, and rake it in; and when the plants are an inch or two high, hoe them to six or eight inches distance.

CORIARIA, the Tanner's, or Myrtle-leaved Sumach.

It is a hardy deciduous, small-leaved, flowering shrub for the shrubbery, adorned with spikes of quinquepetalous flowers.

Class and order, *Dioecia Decandria*.

Characters.] **CALIX**, male and female flowers on distinct plants, having small five-leaved cups. **COROLLA**, five oval petals. **STAMINA**, ten filaments, and oblong antheræ. **PISTILLUM**, five germina, five styles, and simple stigmas. **PERICARPIUM**, none; the petals become a fleshy angular berry, inclosing five seeds.

The species is,

CORIARIA *Myrtifolia*.

Myrtle-leaved Coriaria.] Coriaria with a shrubby, pithy, brown stem, close'y branching from the bottom, and forms a bushy head three or four feet, thickly garnished with oblong, pointed, smallish, bright-green leaves, in pairs opposite; and at the sides and ends of the branches, small spikes of whitish flowers.

Varieties.] Male-flowered Coriaria—Female Coriaria.

This is a proper shrub for any of the common shrubbery compartments, to encrease the variety, where its roots will creep considerably, and send up spawn, or many small suckers, for encrease.

It is easily propagated by suckers from the root, which it affords plentifully, and may be taken off with fibres every autumn or winter.

Layers in autumn will also be rooted in a year.

C O R

CORNUS, Cornel-tree, or Cornelian-Cherry, and Dog-wood.

This genera consists principally of hardy deciduous trees and shrubs, proper for the shrubbery plantations, adorned with oblong leaves, and umbellate white flowers.

Class and order, *Tetrandria Monogynia*.

Characters.] **CALIX**, umbellate flowers, included in a four-leaved coloured involucre, the florets having a very small four-parted cup. **COROLLA**, each floret composed of four oblong acute petals. **STAMINA**, four erect filaments, and roundish incumbent antheræ. **PISTILLUM**, a roundish germen under the receptacle, filiforme style, and blunt stigma. **PERICARPIUM**, a roundish berry, including a bilocular nut, having two kernels.

There are three species of the tree and shrub kind, furnishing several eminent varieties, one of which species grows wild in England; the rest are of American growth, but all hardy enough to succeed here in the full ground.

The species are,

¹**CORNUS** *Mas*.

Male Cornus, or Cornelian Cherry-tree.] Cornus with an upright tree-stem, rising twenty feet high, branching, and form a large head, garnished with oblong leaves, and small umbels of yellowish-green flowers at the sides and ends of the branches, appearing early in spring, succeeded by small, red, cherry-like, eatable, acid fruit.

This species is esteemed both as a flowering shrub, and for its fruit, to preserve for making tarts.

The wood of this tree being extremely hard, derives the name *Cornus*, i. e. of a horn-like hardness and duration, and is said to last as long as iron.

²**CORNUS** *Sanguinea*.

Bloody-twig, or Common Dog-wood.] Cornus with an upright tree-stem, branching ten or twelve feet high, having blood-red shoots, garnished with oblong, pointed, nervous leaves, two inches long; and all the branches terminated by umbellate white flowers, succeeded by black berries.

Variety.] With variegated leaves.

This species grows wild in the hedges in many parts of this kingdom, but is cultivated in the nurseries, and may, with propriety, be introduced in large shrubberies, both for the variety of its foliage and flowers, as well as for the singular appearance of its red shoots in winter, when devoid of leaves.

³**CORNUS** *Florida*.

Virginia

Virginia Dog-wood.] *Cornus* with a tree-stem, branching twelve or fifteen feet high, and fine red shoots, garnished with large obverse heart-shaped leaves; and the branches terminated by umbellate white flowers, having a large involucre, succeeded by dark red berries.

Variety.] *Virginia Dogwood* with a red involucre.

The following are supposed to be only varieties of the above species.

Female Narrow-leaved Virginia Dog-wood.] *Cornus* with an upright tree-stem, branching eight or ten feet high, having very red shoots; spear-shaped, acute, nervous leaves; and the branches terminated by umbellate white flowers, succeeded by red berries.

Blue-berried American Dog-wood.] *Cornus* with an upright stem, branching eight or nine feet high, having beautiful red shoots; large oval leaves, hoary and whitish underneath; and all the branches terminated by umbels of white flowers, succeeded by bunches of large, oval, blue berries.

This variety is remarkably ornamental both in its fine, large, whitish foliage and flowers in summer, and its numerous bunches of elegant blue berries in autumn.

White-berried Pennsylvanian Dog-wood.] *Cornus* with an upright stem, branching eight or ten feet high, and very red shoots; oblong-oval leaves, whitish underneath; and large umbels of white flowers, succeeded by white berries.

White-leaved American Dog-wood.] *Cornus* with an upright stem, branching eight or nine feet high; spear-shaped, acute, smooth leaves; and large umbels of white flowers, and red berries.

Most of these species are strong shooters, well clad with leaves, from two to four inches long, of a lightish colour.

All these trees are elegant furniture for large shrubberies, wilderness-works, and all other ornamental plantations, where they will effect a fine variety with their leaves and numerous flowery umbels in summer, their clusters of berries in autumn, and those of the Dog-wood kind, with their beautiful red shoots, in winter, when the leaves are fallen.

They all prosper in any common soil and exposure; and as to their culture, permit them to assume their own natural growth, except just retrenching any rambling shoots, and clear away suckers from the roots, and all dead wood from the branches.

Propagation of all the Sorts.

Their propagation is by seed, layers, and cuttings, all in the full ground.

By seeds.—The seed of the American kinds generally arrive from thence in spring, which should be sown as soon as possible in a bed of good earth half an inch deep; but they rarely germinate till spring following, unless they are sowed in autumn; therefore the seeds of the Cornelian-cherry, and Common Dog wood, as also those of all the others that ripen here, should be sown in October, and they will, for the general part, grow the succeeding spring; and when the plants are a year old, plant them out in nursery-rows, and when from two to four or five feet high, are of due size for the shrubbery, &c.

By layers.—Let the shoots of the year be layed in autumn, they will all be well rooted, and fit to transplant the autumn following.

By cuttings.—This may be performed in October or November, chusing strong shoots of the year, cut ten or twelve inches long; plant them three parts in the ground, and they will be well rooted by autumn following.

Suckers from the roots will also make good plants.

When these shrubs are from two to four or five feet high, they are fit for the shrubbery.

CORONILLA, Jointed-podded Colutea, and *Emerus*, or Scorpion-Sena.

Of this genus there are some shrubby evergreens and deciduous shrubs, proper for the green-house and shrubbery collections, ornamented principally with pinnated many-lobed leaves, and clusters of papilionaceous yellow flowers, succeeded by long jointed seed-pods.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX is monophyllous, compressed, erect, and bifid. COROLLA is papilionaceous; the vexillum heart-shaped, and the sides reflexed; the wings oval, and join at top; and the carina short, compressed, and pointed. STAMINA, ten filaments, nine of them united, the other stands separate, and small antheræ. PISTILLUM, an oblong taper germen, bristly style, and obtuse stigma. PERICARPIMUM, a long, taper, jointed pod, having many seeds.

The species are as follow: the first four are low, rather tender shrubs, and are commonly retained in pots for shelter of a green-house in winter.

¹CORONILLA *Glaucæ*.

Sea green-leaved Coronilla.] Coronilla with a shrubby stalk, branching two feet high; pinnated evergreen leaves, of about five pair of glaucous-coloured lobes, terminated by an odd one; and, from the sides of the branches, many roundish bunches of bright yellow odoriferous flowers.

²CORONILLA *Argentea*.

Silvery-leaved Cretan Coronilla.] Coronilla with a shrubby stalk, branching two feet high; pinnated leaves of nine or eleven silvery lobes; and roundish bunches of yellow flowers.

³CORONILLA *Valentina*.

Valentian Nine-lobed Coronilla.] Coronilla with a shrubby stalk, branching a foot or eighteen inches high; pinnated leaves of about nine pair of small lobes; and the branches terminated by bunches of yellow flowers.

⁴CORONILLA *Juncea*.

Rush-lobed Spanish Coronilla.] Coronilla with a shrubby stalk, branching two feet high, garnished with leaves of five and three very narrow, spear-shaped, fleshy lobes, and small bunches of bright yellow flowers.

The following is a hardy, large, very beautiful, deciduous, flowering shrub, and remarkably floriferous.

⁵CORONILLA *Emerus*.

Emerus, or Scorpion-Sena.] Coronilla with a shrubby stem, branching numerous six or eight feet high, closely garnished with winged leaves of three pair of lobes, terminated by an odd one; and at the sides of the branches, numerous long flower-stalks, each supporting two or three large yellow flowers, succeeded by longish pods.

Variety.] Dwarf Scorpion-Sena.

The flowers of all these shrubs are of the papilionaceous or butterfly kind, being composed of a standard, two wings, and a *carina*, or keel, see the *Characters*, appearing commonly in May and June in great plenty; and the *Emerus*, or Scorpion-Sena, appears covered with them, continuing long in beauty; and all the sorts are succeeded by jointed pods in autumn, filled with ripe seed.

The first four species are rather tender, and, although they will live in open air in mild winters, they are impatient of severe weather; they should therefore, for the general part, be potted, to be moved to shelter of a green-house or glass-frame in winter; and others may be placed in a sheltered situation in the full ground, to take their chance.

The fifth sort, *Scorpion-Sena*, and variety, are hardy and elegant flowering shrubs for the principal shrubbery compartments in gardens of any extent, and there are but few hardy shrubs that make a finer appearance.

Propagation of all the Sorts.

The first four species are propagated by seeds in spring, either on a warm border, or in a slender hot bed; but the latter will forward them greatly, sowing the seeds in pots of rich earth half an inch deep, and plunge them in the hot-bed; and when the plants are two or three inches high, prick them in separate small pots, allowing shade, water, and air, and harden them gradually to the full air in June, in which let them remain till October, then moved to shelter of a frame during winter, but cover them only in time of frost.

The *Scorpion-Sena* may be increased plentifully both by seeds, and by layers and cuttings.

Sow the seeds in March, in a bed of light earth, and cover them half an inch deep, giving occasional waterings in dry weather, and the plants will rise in a month or six weeks; and when they have had a year or two's growth, transplant them from the seed-bed in nursery rows, and in two or three years after they will be large enough for the shrubbery.

By layers. It may be done in autumn or winter, chusing the one-year's shoots, giving them a gentle twist, and they will be rooted by the winter following.

By cuttings. Plant some of the young shoots in October or November in a shady border, giving water the following spring and summer, and many of them will be rooted by autumn.

COROLLA, Corolla, or Little Crown, the botanic name for the flower-leaves, i. e. the beautiful coloured leaves of the flower, which immediately surround and defend the organs of generation, and stand within the calix, where there is any.

This conspicuous and beautiful part of plants, the Corolla, is designed not only as an ornament to the respective plants, but also to defend and nourish the tender generative organs, till they have performed their fecundating function, &c. and is therefore by Linnæus, in assimilating the animal and vegetable kingdoms, distinguished by the name of *auleum floris*, or the palace in which the nuptials of the plant is celebrated.

The

The Corolla may be said to consist of two parts, the petals, and the nectarium; the last of which, however, is rather a striking superfluity, or occasional appendage in some, than a necessary part of every flower, see NECTARIUM; so that the petals are always to be considered as the principal part of the Corolla.

A Corolla of one petal is termed *monopetalous*; of two, *dipetalous*; of three, *tripetalous*; of four, *tetrapetalous*; of five, *pentapetalous*, or *quinquepetalous*; of six, *hexapetalous*, or *sempetalous*; of eight, *octapetalous*; or of many *polypetalous*; though all flowers, having more than one petal, are species of *polypetalous*.

Observe, in respect to number, that, in the characteristic description of the Corolla, the number of petals are always to be determined from their single or common state, never from the doubles, which are only accidental varieties; as, for example, the *cheiranthus*, or wallflower and stock-gilliflowers, in their common state, the Corolla consists only of four petals, but in the doubles they are innumerable; and so of all other flowers that are apt to run into doubles, which are properly enough styled luxuriant flowers. See LUXURIANS *Flos*, and PLENUS *Flos*.

The real numbers of petals in the Corolla is determined from the base; that is, when the Corolla appears of two, three, or many parts or divisions, continued to, or very near the bottom, it is considered as so many distinct petals, notwithstanding the base of the several petals may connect, as is the case of the mallow tribe, the genus *Narcissus*, and many others; but when the limb, or upper spreading part of the Corolla, is divided only about half way, or a little more or less, into several parts, it is considered only as one petal, *monopetalous*, divided into so many segments or parts.

Segments or divisions are very frequent in monopetalous flowers, which very commonly have their limb divided into five parts; in polypetalous flowers these divisions of the real petals seldom prevail.

In respect to the figure of the Corolla and petals, that, in monopetalous flowers, there being but one petal, it is either bell-shaped, funnel-shaped, salver-shaped, wheel-shaped, ringent or masque-shaped, as explained below; and in a polypetalous flower, the Corolla is either regular, by having all its petals of equal figure, magnitude, proportion, and position, as in tulip, *Narcissus*, lily, &c. or

irregular, by the petals assuming different figures, sizes, and position, in the same Corolla, as in *aconitum*, or monk's hood, balsamine, columbine, and lark-spur, &c.

In a monopetalous Corolla, the lower hollow part is called the tube, the upper spreading part the limb, the opening of the tube the chaps or jaws, *faux*. See TUBUS, LIMBUS, and FAUX.

In a polypetalous Corolla, the lower part is termed the claw, *unguis*; the upper spreading part *lamina*. See UNGUIS and LAMINA.

The Corolla has different terms, according to the figure it assumes, as follow.

Corolla Campanulata, a bell-shaped Corolla, consists of one petal, regular and hollow like a bell, as in the genus *campanula*, *convolvulus*, and deadly night shade.

Corolla Infundibuliformis, a funnel-shaped Corolla, consists of one regular petal, with a conic shaped limb, standing upon a long tube, as in *datura*, or thorn-apple, oleander, tobacco, and marvel of Peru.

Corolla Hypocrateriformis, a salver-shaped Corolla, has one regular petal, having a plane or flat-spreading limb standing on a very short tube, as in periwinkle, &c.

Corolla Rotata, a wheel-shaped Corolla, has one regular petal, having a plane or flat limb without any tube, sometimes entire, and sometimes divided, as in *borago*.

Corolla Ringens, a gaping or grinning Corolla, has one irregular petal, shaped sometimes like a masque or snout of an animal with two lips, as in snap-dragon, or calve's snout; sometimes is terminated behind by a nectarium, in form of a tube, or spur of a fowl, as obtains in *antirrhinum linaria*, or toad-flax. See RINGENTUS and PERSONATUS.

Corolla Labiatus, a labiated or lip Corolla, having two lips, and is a species of *Corolla Ringens*. See LABIATUS and VERTICILLATA.

Corolla Cruciformis, a cruciforme, or cross-shaped Corolla, composed of four equal petals, that spread at top on their claws in form of a cross, exemplified in stock-gilliflower, ladies-smock, and the other numerous flowers of the class *tetradynamia*.

Corolla Papilionacea, a papilionaceous or butterfly shaped Corolla, composed of four or five irregular petals, which, from their figure and position, bear an obvious resemblance to a butterfly with its wings expanded, exemplified in the pea, bean, kidney-bean, and

and laburnum, &c. the petals are characterized by distinct names; the upper one is called the standard, *vexillum*; the two side ones the wings, *alæ*; and the lowermost one, sometimes concave and divided, is called the keel, *carina*, from its resemblance to the bottom or keel of a boat; is sometimes of one petal, and sometimes two united. See PAPILIONACEA.

Most of the plants in the class *diadelphia* have papilionaceous flowers.

Corolla Regularis Polypetala, a regular polypetalous Corolla, having two, three, or many regular petals, of equal shape, magnitude, and position, as in rose-campion, holly-hock, tulip, lily, &c.

Corolla Irregularis Polypetala, an irregular polypetalous Corolla, consists of several irregular dissimilar petals, generally accompanied with a nectarium, as in *aconitum*, balsamine, lark-spur, *orchis*, or bee-flower, *cypripedium*, or lady's-slipper; and most of the papilionaceous flowers come also under this denomination. See IRREGULARIS Flos.

With respect to duration of the Corolla, the petals sometimes fall off immediately after their expansion, or endure but a few hours, or sometimes but one day; sometimes they are of several days, or even weeks, duration, and sometimes the Corolla withers on the plant without dropping at all, as often obtains in the cucumber, in which the flower sometimes remains, on the end of the fruit, till fit to gather; but in most plants the Corolla falls off with the stamina and other parts soon after the fecundating function is effected; to assist which, by defending the generative organs, is apparently the main design of the Corolla.

CORTUSA, Bear's ear Sanicle.

It furnishes two very low, herbaceous, flowery perennials, crowned by umbels of monopetalous, wheel-shaped, auricula-like flowers, having five stamina and one style.

The species are,

¹CORTUSA *Matthioli*.

Bear's-ear Sanicle of Matthioli] Cortusa with a fibrey root, crowned by many oblong, heart-shaped, indented leaves, in a cluster, and among them round flower-stalks six inches high, terminated by umbels of fine red flowers longer than the calix.

²CORTUSA *Gmelini*.

Bear's-ear Sanicle of Gmelin.] Cortusa with a fibrey root, crowned by a tuft of heart-shaped leaves, and flower-stalks four inches

high, terminated by umbels of pale red flowers shorter than the calix.

They are natives of mountainous rocky parts abroad, so must have a dry lean soil; or may be kept in pots of dry sandy earth, placed in the shade, and in summer must be duly watered; and their propagation here is by slipping the roots in October.

CORYLUS, the Hazel or Nut-tree, Filbert, &c.

This genus furnishes two species only, both of them of the large shrub kind, hardy and deciduous, and of which there are several varieties, valuable in gardens for their fruit, as also by way of variety in large shrubbery and wilderness works.

Class and order, *Monoecia Polyandria*.

Characters.] CALIX, male and female flowers, remote on the same plant; MALES are collected in a long katkin, or scaly amentum, each scale forming a calix. COROLLA none. STAMINA, many very short filaments in each scale, and oblong erect antheræ; FEMALE FLOWERS are included in the future bud sitting close to the branches, having a thick two-leaved leathery calix, enlarging to the length of the fruit, and lacerated at the margin. PISTILLUM, a roundish germen, two styles, and simple stigma. PERICARPIUM, none; the germen becomes an oval nut, pointed at the top.

Botanists admit of but two real species of *Corylus*, and that the Hazel, Filbert, Cob-nut, &c. are all varieties of the same species, and that the common Hazel or Nut-tree of the woods is the original species.

The species are,

¹CORYLUS *Avellana*.

Avellana, or Common Hazel or Nut-tree.]

Corylus with an upright tree-stem, very branchy, and forms a full head from ten to twenty feet high, garnished with large roundish, pointed leaves, having oval stipulæ, and male flowers, growing in long yellowish katkins, and female flowers close to the branches, appearing in spring, of a red colour, succeeded by the fruit in large cups, ripening in autumn.

Varieties.] Common Wood-nut with a white-skinned kernel—Red Wood nut, having a red-skinned kernel.

Large Cluster Wood-nut—The Nuts grow in large clusters, and the Nuts are also large and fine, and very proper for garden culture.

Great Cob-nut—A remarkably large round Nut with a thick and very hard shell, more valuable

valuable for its size for variety, than any particular excellency in its kernel.

Long-nut—is an inch and half, or two inches long, broadish and rounded at the top, but does not kernel well.

Barcelona, or Spanish-nut—A large, roundish, thin-shelled Nut, always remarkably well-kernelled, which is exceeding sweet and good, and will ripen in England, so is a very proper sort for culture, and the tree is a strong shooter.

Filbert-Nut-tree—The branches grow more erect, and the *stipulæ* more oblong than the other kinds, and the fruit is oblong, large, thin-shelled, and well filled with exceeding sweet kernels, and the Nuts frequently grow in clusters; of this there are two notable varieties—White-skinned Filbert—Red-skinned Filbert—The Red sort is in most esteem, being coveted for the beauty of its red kernel. The trees of these two varieties are very distinguishable; those of the White sort have the shoots and leaves of a light green colour, which of the Red kind are of a dark or reddish-green. Both the varieties are good bearers, and will succeed almost any where; they are therefore well worth culture in every garden or orchard.

³*CORYLUS Colurna.*

Colurna, or Dwarf Byzantine Nut-tree.]
Corylus with an upright shrubby stem, branching four or five feet high; roundish, pointed leaves, and narrow acute *stipulæ*; and large round Nuts growing in clusters.

The flowers of all these trees are male and female, at a distance on the same tree; the males appear in long scaly amentums, formed in autumn and winter, and the females, or fruitful flowers, come out in spring, in clusters close to the branches, having thick, two-leaved, torn cups, appearing of a reddish colour, and the calix incloses the fruit, and accompanies it to maturity, generally one Nut in each cup.

All the sorts of *Corylus* are very hardy, and will prosper in almost any situation and soil, high or low, or on the sides of hills, as is evident from the common Hazel growing wild in such abundance in woods, wilds, forests, and field hedges, in every county of the kingdom, and from which the Nuts are collected that supply the different markets; the trees also turn out to good account when growing in coppices, to cut as underwood, and for poles for various uses, as hoops, spars, hurdles, handles to husbandry implements, walking-sticks, fishing-rods, and many other

uses, and for which purposes they will afford a falling every fifth, seventh, or eighth year, according to the uses for which they are designed.

For purposes in gardening, several of the varieties are worthy of culture, for the sake their fruit; particularly the Cluster-nut, Large Cob-nut, Barcelona-nut, and the two varieties of Filberts; all of which may either be trained as high standards, half standards, or dwarfs. When required for standards, they should be planted at fifteen feet distance, either in the garden, or on the edge of orchards, &c. or they may be dropped singly in different parts, to form the greater variety; and in pleasure-grounds, some may be disposed by the sides of shady walks, or other parts of the wilderness or shrubbery works contiguous to the walks, some as dwarfs, others as half and full-standards, where they will exhibit variety as common shrubs, and the progress of the fruit will afford entertainment in excursions through the plantation, as well as furnish a supply for the desert.

Observe, when you design them to form full standards, you should train them with a single stem five or six feet high, at which height suffer them to branch out and form a head, according to their natural growth; but for half standards, a three or four feet stem is sufficient; and for dwarfs, train them with a single stem to a foot and half in height, then top them, and they will branch out, and form a low spreading head.

All the culture these trees require, after being planted out where they are to remain, is to clear the bottom annually from suckers arising from the root, and the stem from all side-shoots; and as to their heads, let them, for the general part, take their natural growth, except just retrenching any very rambling shoot or branch.

But sometimes these trees are planted to form a kind of hedge, setting them five feet distance; so leave them entirely to nature to shoot from the bottom, sides, and top, in their own way; but these never produce so large, nor fine-flavoured fruit, as trees with one stem, and stand at such distances, that their heads have full scope to spread regularly every way.

When a full plantation of these trees are designed for their fruit, I should advise planting them in rows not less than fifteen or twenty feet distance, nor less than ten or fifteen feet asunder in the lines.

When designed to plant a coppice of common Nut-trees, for poles, &c. they should be previously raised from the Nut in the nursery way; and, when two or three feet high, plant them out where they are to remain, in rows five feet distance, and a yard in the rows, and they will be fit for the first fall in eight, ten, or twelve years, according to the uses they are designed for, and every fifth, sixth, or seventh year afterwards.

Propagation of all the Varieties.

All the sorts of *Corylus* may be propagated with facility by planting the Nuts, by layers, suckers from the root, and by grafting and budding.

By planting the Nuts: this should be done in spring, but until the arrival of that season it is proper to preserve the Nuts in sand, in an airy room or shed, and in February plant them in drills near two inches deep, and the plants will appear in six or eight weeks, which, when a year old, plant out in nursery-rows, and there train them two or three years, for the purposes wanted, i. e. either as standards, half standards, or dwarfs; then transplant them into the garden. It is to be observed, that in raising these trees from the Nut, the sorts are not to be always depended on; for, like other seedling trees, they often vary, so that the most certain method to continue the respective sorts is by layers, &c. observing, however, that in raising from Nuts, sometimes trees are obtained, which produce Nuts as good, and sometimes better than those from which they were raised.

By layers: this is one of the most certain methods of continuing the respective varieties distinct, for layers of the Cluster-nut never fail to produce fruit exactly of the same kind and manner; the same of the Cobs, Barcelona, and Filberts; and this is a very easy and expeditious method of propagation, for every twig layed will readily grow; therefore, in autumn or winter, having recourse to some low-growing trees, let some of the lower branches, that are well furnished with young shoots, be pegged down in the ground, then lay all the young shoots thereof in the earth with their tops out, every one of which will root and advance in length, and be fit to transplant by autumn following, when they should be separated and planted in nursery-rows two feet asunder, and trained as observed of the seedlings: but when any considerable quantity are to be raised this way, it is eligi-

ble to form stools for that purpose, by previously a year before heading down some trees near the ground, to throw out a quantity of shoots near the earth convenient for laying, and they will furnish a supply for that use annually.

Suckers, arising from the roots of trees raised by either of the above methods, if taken up in autumn, winter, or spring, with good fibres, will also grow, form proper plants, and produce the same sort of fruit as their parent plant; and suckers of these may also be used for the same purpose.

By grafting and budding: these methods have also the same effect as layers, of continuing any particular variety with certainty, and the operation is to be performed in the usual way on stocks of any of the varieties of this genus. See GRAFTING, &c.

CORYMBUS, a mode of cluster-flowering, resembling the form of a cluster of ivy-berries, and differs from the umbel and racemus, and other modes of cluster-flowering. See UMBELLA and RACEMUS.

A Corymbus-cluster is distinguishable, in that many partial flower-stalks arise from different parts of the common stalk; and although of unequal lengths, by coming out higher or lower on the main stalk, yet they all rise to the same height, so as that the flowers they support forms a flat and even surface at top, exemplified in *spiraea opulifolia*, *tanacetum*, &c. and differs from an umbel, in which all the partial flower-stalks proceed from one point or common centre, and rise also to an equal height. See UMBELLA.

A Corymbus is either simple or compound; simple, when the partial flower-stalks have no branches; compound, when they branch out into several ramifications, yet so as to form an even surface at top.

COTYLEDON, Navel-wort, *Cotyledon*.

The plants are succulent perennials, both of hardy nature, and for the green-house and stove, from half a foot to a yard and half high, adorned with roundish and oblong, thick, fleshy leaves, and monopetalous, bell-shaped, yellowish flowers, in spikes and umbels.

Class and order, *Decandria Pentagynia*.

Characters.] CALIX monophyllous and five-parted at top. COROLLA is monopetalous, bell-shaped, and five-parted, at the brim. STAMINA, ten erect filaments, and four-furrowed antheræ. PISTILLUM, five germina, and styles, and simple stigmas. PERICARPIUM,

RICARPIUM, five oblong, ventricose, univalvular capsules, having many small seeds.

The species are,

¹COTYLEDON *Umbilicus*.

Umbilicated Cotyledon, or Common Navel-wort.] Cotyledon with round, target shaped, hooded, serrata-indentad, fleshy leaves, directly from the root, on foot-stalks joined to the middle, and the upper surface umbilicated like a navel; and amidst them branching leafy flower-stalks, from half a foot to a yard high, terminated by long spikes of erect close-fitting flowers, of different colours in the varieties.

Varieties are] Umbilicated Cotyledon with yellow flowers—with reddish flowers—with whitish flowers—with streaked flowers—with creeping roots—with tuberous roots.

This species and varieties grows wild in England upon old walls, buildings, and rocky places; and in gardens may ornament artificial ruins, rock-work, and grottos.

They derive the name Navel-wort from the form of its umbilicated leaves.

The three following are shrubby green-house exotics from Africa.

²COTYLEDON *Orbiculata*.

Orbiculate-leaved Cotyledon.] Cotyledon with thick, succulent, ligneous, perennial stalks, emitting crooked irregular branches, and grows from one foot to a yard or more high, ornamented with roundish, plane, fleshy, entire leaves, having purplish edges; and at the ends of the branches, umbellate clusters of pale yellow flowers.

³COTYLEDON *Hemispherica*.

Hemispherical-leaved Cotyledon.] Cotyledon with a thick, succulent, perennial stalk, very branchy, and but six or eight inches high, garnished with semi-globular thick leaves, one side being convex, the other plane, having purplish edges; and at the top of the branches, several greenish - purple - tipped flowers.

Variety.] With spotted leaves.

⁴COTYLEDON *Spuria*.

Long Spatulate-leaved Cotyledon.] Cotyledon with thick, succulent, ligneous, perennial stalks, branchy, and from one to two or three feet high; long, narrow, spatulate-shaped, fleshy, alternate leaves; and yellow flowers, on long fleshy foot-stalks at the ends of the branches.

The following is a stove plant from India and Egypt.

⁵COTYLEDON *Lacinata*.

Cut-leaved Cotyledon.] Cotyledon with an upright, jointed, succulent, perennial stalk, a foot high; broad, trifid, thick, succulent, greyish, opposite leaves; and from the ends of the branches, golden-yellow quadrifid flowers.

The last four species are perennial in stalk and branches, are very succulent, and become ligneous or shrubby; the leaves are also succulent, commonly of a greyish colour, and remain the year round. The flowers are universally monopetalous, bell, or funnel-shaped, which in the last four sorts are produced on long, thick, fleshy foot stalks, appearing at different times of the year; and only the first sort produce seeds in England.

For purposes in gardening, the *Cotyledon Umbilicus* may be introduced to adorn rock-work, ruins, &c. or will succeed in any dry gravelly soil; and the second, third, and fourth sorts, exhibiting a curious singularity in their general habit, merit a place in the green-house collection; as likewise the fifth sort for the stove; observing, that these last four sorts, being very succulent, must always be retained in pots of dry sandy or rubbishy compost, and managed as other succulents of the green-house and stove departments. See SUCCULENT PLANTS, &c.

Propagation.

The first sort may be raised from seed in any dry gravelly soil, or scattered in the crevices of rock-work, grottos, or old buildings, and covered with earth; the plants will come up, and afterwards propagate themselves.

All the other sorts are easily propagated by cuttings of their succulent branches any time from May till August; the cuttings may be from three to five or six inches long, which, previous to their planting, ought to lie a week or ten days, to dry over the cut part; then plant them in pots of dry compost, as prepared for other succulents, see COMPOST; and then, as to the green-house sorts, place them either in the green-house, or a frame, to have shelter from wet, and occasional shade, though it would be of particular advantage to plunge all the sorts in a bark bed, giving occasional shade, and water once a week, and they will be rooted in a month or six weeks, when those of the green-house should be hardened to the full air for the remainder of the summer.

COTYLEDONES, Cotyledons, the side-lobes or covers of the seed, which be-

comes also the two first leaves of the plant; called also Cotyledons, or the feminal or seed-leaves; are generally smooth and fleshy, and most commonly two in number, as in cucumber, and most other plants, and are very different from the proper leaves that are afterwards produced.

The lobes accompany the plant for some time after its eruption from the earth, till having acquired sufficient strength and growth, the feminal leaves become useless, wrinkle, wither, and die away.

CRAMBE, Sea Cabbage, or Sea-beach Kale, or Sea Colewort.

The plants are herbaceous esculents, consisting of perennial roots, producing annually large cabbage-like leaves, spreading on the ground, and robust flower-stalks; and the young shoots of the plant, just issuing from the earth, are excellent eating.

Class and order, *Tetradynamia Siliquosa*.

Characters.] **CALIX**, four oval, patent, deciduous leaves. **COROLLA**, four large, broad, spreading, cruciforme petals. **STAMINA**, four long and two short filaments, two-parted at top, and single antheræ. **PISTILLUM**, an oblong germen, no style, but a thick stigma. **PERICARPIUM**, a roundish berry, containing one seed.

The species is,

CRAMBE Maritima.

Maritime, or Sea-Cabbage.] Crambe with creeping, perennial, white roots, crowned by very broad, thick, smooth, grey-coloured, annual leaves, divided at the edges, and spreading near the ground; and between them a robust very-branchy flower-stalk a foot and half high, having all the branches terminated by loose spikes of white flowers in June, succeeded by berry-like pods the size of large peas.

Varieties.] With deeply cut leaves—with yellowish flowers.

This plant and varieties grows wild on the sea shores in many of the maritime counties of England, but is now cultivated in many gardens, as a choice esculent; and the young robust shoots of its leaves and flower-stalks, just as they issue forth from the earth, in the manner of asparagus shoots, are then in the greatest perfection for use; at which period they appear white, as if blanched, which, when boiled, eat exceeding sweet and tender; and its principal season for use is April and May.

This plant may also be employed in the

pleasure-ground as a flowering perennial, for the stalks divide into fine branchy heads of flowers.

Propagation and Culture.

It is propagated by seeds sown in any common light earth in autumn or spring, in the place where the plants are to remain, which, when two years old, will produce shoots fit for use, and will multiply exceedingly by the roots, and continue many years.

To cultivate this plant as an esculent in the kitchen-garden, it is proper to have them in beds four feet and half wide, with two foot wide alleys between bed and bed, for the convenience of landing them up annually in autumn, that the shoots may be blanched a good length; and the lighter and more sandy or gravelly the soil the better, though the plants will succeed tolerably in any common light soil of a garden. Having dug and prepared the beds the width as above, draw three shallow drills lengthways of each bed, and scatter the seeds therein thinly, covering them half an inch deep; when the plants come up thin the rows, leaving the strongest plants a foot asunder; keep them clean from weeds all summer; and in autumn, when the leaves decay, spread an inch depth of light earth from the alleys over the beds; after this, nothing more is required till the following spring and summer, when the care of weeding is to be repeated; and in autumn earth the beds from the alleys as before, but must now be three or four inches deep; the spring following, in March, April, and May, the plants will produce shoots fit to cut for use; observing, as the heads make their appearance through the earth, to open the soil a little, and cut the shoots four or five inches within the ground.

The same plantation continues many years, and the roots produce a fresh crop annually.

Their general culture is keeping them clean from weeds, and every autumn clear away all the large leaves, and land up the beds from the alleys three inches deep, to maintain a due depth of soil over the roots for the heads to shoot through, that they may be blanched at least four or five inches in length; and early in spring loosen the top of the beds with a fork, and rake them smooth.

To cultivate this plant for ornament, sow the seed either where you design they shall remain, or in a bed, and transplant them in autumn.

CRASSULA,

CRATÆGUS, Wild Service-tree, Hawthorn, &c.

The plants are of the tree and shrub kind, hardy, and of the deciduous tribe, valuable for æconomical and ornamental purposes in gardening, and of stature from five to fifty feet, adorned with simple leaves, in some divided, others entire, and clusters of pentapetalous white flowers in May and June, succeeded by bunches of red berries in autumn.

Class and order, *Icosandria Digynia*.

Characters.] **CALIX** is monophyllous, five-parted, patent, and permanent. **COROLLA**, five roundish concave petals inserted into the calix. **STAMINA**, twenty filaments inserted into the calix, and roundish antheræ. **PISTILLUM**, a germen under the corolla, two filiforme erect styles, and capitated stigmas. **PERICARPIUM**, a roundish, fleshy, umbilicated berry, containing two longish hard seeds.

There are about six or eight species retained in the English gardens, some of which admit of several curious varieties.

The species are,

¹**CRATÆGUS Oxyacantha**.

Oxyacantha, or *Common Hawthorn*, or *White-thorn*.] **Cratægus** with a robust trunk, branching from the bottom upward to ten or fifteen feet high, the branches armed with thorns; obtuse, nearly trifid, sawed leaves; and numerous clusters of white flowers from the sides and ends of the branches, succeeded by bunches of dark red berries called Haws.

This is a most useful tree in forming our hedges, and it grows wild all over Europe.

Other varieties of this are,

Double-blossom Hawthorn—grows like the *Common Hawthorn*, only the flowers double, large, and grow in large clusters all over the branches, of great fragrance and beauty.

Scarlet-berried Hawthorn—grows twelve or fifteen feet high; large leaves and flowers, and exceeding large bright-scarlet fruit.

Yellow-berried Virginia Hawthorn—grows ten or fifteen feet high, having its buds in spring yellow, and fruit of a golden yellow colour.

White-berried Hawthorn—A low growing tree, producing small whitish fruit.

Maple leafed Hawthorn—grows fifteen or twenty feet high; large whitish leaves, large bunches of flowers, and shining red fruit.

Glastonbury-Thorn—grows twelve or fifteen feet high, and is like the common Hawthorn in growth, leaves, flowers, &c. only with

this difference, that it generally flowers in winter, which is commonly said to happen on Christmas-day; it, however, has no exact time of flowering, although it sometimes happens to be in bloom about that season, even on the very day, yet it frequently flowers in the end of January, and in February. The story of this tree blowing on Christmas-day, proceeds from the tradition of the original tree near Glastonbury, which is said to have been the staff of Joseph of Arimathea, when he came over to Britain and founded the first Christian church; that having on that day stuck his staff into the ground, it immediately shot forth and bloomed, and is said to have continued to blow on Christmas-day ever since; so is universally distinguished by the name of Glastonbury-Thorn, and is retained in many shrubberies by way of curiosity and variety.

²**CRATÆGUS Aria**.

Aria Theophrasti, *Wild Service*, or *White-leaf-tree*.] **Cratægus** with an upright large trunk, dividing upward into a branchy head, growing twenty or thirty feet high, having all the young branches spotted with a mealy down; oval unequally-ferrated leaves, woolly and very white underneath; and large bunches of white flowers at the ends of the branches, succeeded by clusters of red berries. The leaves are about three inches long, and half as broad.

³**CRATÆGUS Terminalis**.

Maple-leafed Wild Service-tree.] **Cratægus** with an upright large trunk, and very branchy spreading head, rising forty or fifty feet high; heart-shaped, septangular, divaricated-lobed leaves, hoary underneath; and large bunches of white flowers at the ends of the branches, succeeded by clusters of large, reddish-brown, eatable berries.

Other varieties are] With round ferrated leaves—with round slightly-cut leaves.

The fruit of this species being of an agreeably acid flavour, is often served up in deserts to table; and, as the trees of the common sort grow wild in many parts, the country people gather the fruit in autumn for market, known by the name of Service-berries. The leaves are three or four inches long, and three broad.

⁴**CRATÆGUS Azarolus**.

The Azarole-thorn] **Cratægus** with an upright trunk, branching irregularly twelve or fifteen feet high; broad, obtuse, nearly trifid, ferrated leaves; and large white flowers in clusters

clusters from the sides of the branches, succeeded by large, red, eatable berries, of an acid flavour.

Varieties are] Azarole with strong thorns—without thorns—with jagged leaves—with double flowers.

The leaves bear some resemblance to those of the Common Hawthorn, but are much larger, with broader lobes.

⁵*CRATÆGUS Coccinea.*

Scarlet Virginia Cratægus, commonly called Cockspur-Hawthorn.] *Cratægus* with an upright trunk, divided upward into a strong branchy head, rising from ten to twenty feet high; large, oval, angulated-bending, serrated, smooth leaves; and very large clusters of flowers from the sides of the branches, succeeded by pear-shaped scarlet fruit.

Varieties are] *Scarlet Cratægus* with many strong recurved thorns like a cock's spur, hence the appellation Cockspur-Hawthorn—*Scarlet Cratægus* without thorns.

Both the varieties are fine furniture for all ornamental plantations, as they flower plentifully, and their fruit appears beautiful in autumn and winter.

⁶*CRATÆGUS Crus-galli.*

Cockspur Cratægus, commonly called Virginia Azarole.] *Cratægus* with an upright robust trunk, branching irregularly ten or fifteen feet high, armed with long sharp thorns; oval-spear-shaped, sawed, smooth leaves; and large white flowers in bunches, succeeded by dark red berries in autumn.

Varieties are] With pear-tree leaves—with plum-tree leaves, very long spines, and large fruit—with plum leaves, short thorns, and small fruit.

⁷*CRATÆGUS Tomentosa.*

Tomentose Gooseberry-leaved Virginia Cratægus.] *Cratægus* with a shrub-like stem, branching irregularly six or seven feet high, closely armed with thorns; oval-wedge-fashioned, angular, sawed leaves, woolly underneath; and small white flowers, succeeded by yellow fruit.

⁸*CRATÆGUS Viridis.*

Green-leaved Thornless Virginia Cratægus.] *Cratægus* with a thornless stem and branches; lanceolate-oval, nearly trilobate, serrated, smooth leaves, green on both sides.

The flowers of all these trees, in their common state, have a corolla of five roundish petals, mostly white, appearing principally in May and June, ripen fruit in September, which are all of the berry kind, and which,

in many sorts, appear very ornamental great part of winter, till devoured by the birds.

All these trees are hardy; the first three species grow naturally in England, as well as in most other parts of Europe, the *Azarole* in France and Italy; all the others are principally of American growth, but all the sorts grow freely here in any situation in the open ground.

The first species, *Cratægus Oxyacantha*, or Common Hawthorn, in its natural state, is a most valuable tree, universally known and esteemed for its great usefulness in forming hedges for fences, commonly called quick-set hedges, and for which use there is scarce any deciduous tree so well adapted, see *HEDGES*; and its several varieties are of great use for ornamenting our shrubberies and wilderness-works, as they will prosper any where.

All the other species and varieties have great merit as ornamental deciduous trees, and are particularly well adapted for large shrubberies and other ornamental plantations, and to form clumps in parks; and some of the large sorts to disperse singly in parks, or extensive lawns, suffering them all to retain their own natural growth.

Propagation, &c.

All the species are raised abundantly from seeds in the full ground; and to continue the varieties distinct, they may be budded or grafted upon stocks of the common Hawthorn, for all the sorts will readily take upon that stock, or upon one another.

By seeds, i. e. the fruits—The Hawthorn never fails to ripen Haws abundantly, which may be collected with facility from the hedges of fields, &c. in September and October; the fruit of the two Service-trees may also be found plentifully in many places; and those of the foreign sorts also ripen in our gardens; but all the sorts may be had cheap enough of the nurserymen, and the best time to sow them is soon after they are ripe; that is, in October or November, or very early in spring, in beds of light earth, either broad-cast, or in drills, and cover them an inch and half deep; but as most of these seeds often remain in the ground till the second spring, it is therefore customary with many, previous to sowing, to bury them in a heap in a trench, in dry-lying ground, for a year, as is commonly practised to the common Haws, holly-berries, and some other stony seeded sorts, see *SOWING SEED*; they will be all the while preparing

preparing for vegetation, so that if buried in October, November, or December, &c. suffering them to lie until October or November following; then sow them, as above directed, and they will mostly come up the spring after; though it is observable, that those sowed at once in the beds an inch or two deep, they, by having the constant benefit of the sun's influence, air, and occasional showers, generally all come up freely the second spring after sowing, and most commonly shoot more regular and strong than those of the other method.

In either method of sowing, be careful to weed the beds, and when the plants begin to appear, occasional watering in dry weather will be of much advantage in forwarding the growth of the seedlings.

In the autumn or spring after the plants come up, some of the strongest of the quick or Hawthorn seedlings will be proper sets to plant immediately for a hedge, and the rest may either then, or the year following, be transplanted from the seed-bed in nursery-rows, to remain a year or two, or till wanted; though when they are from one to two or three years old, they are of the most eligible size to plant for hedges. See HEDGES.

Let all the other seedlings be also transplanted from the seed-bed when a year or two old, in nursery-rows two feet distance, and half that in each row, to remain three or four years, or till they are from about three to five or six feet high, when they will be of proper size for the shrubbery, or any other plantation.

By budding, &c.—Any of these trees may also be propagated with facility by that method, which is the most certain way to continue the varieties distinct; all the sorts take upon one another, but the Hawthorn stock of two or three years old is most commonly used, and the operation is to be performed in the usual manner. See INOCULATION, &c.

Layers of the youngest branches of most of the sorts in autumn, will often be rooted in a year or two.

Cuttings of the young shoots will also sometimes grow.

CREPIS, Bastard Hawkweed.

It furnishes herbaceous ornamental plants for the pleasure-ground, consisting principally of two beautiful annuals, rising a foot and half high, having their branches terminated by ligulated compound red and yellow flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, a compound flower, having a double general cup; the outer one short, patulous, and deciduous; the interior one oval, furrowed, have numerous scales, and permanent. COROLLA, numerous, monopetalous, ligulated, hermaphrodite florets, five parted at top, and imbricated. STAMINA, five short filaments, and cylindric antheræ. PISTILLUM, a germen, small style, and two reflexed stigmas. PERICARPIMUM none. SEMEN, one seed crowned with down under each floret.

There are several species, but not more than two of any great merit, or that are commonly retained in the English gardens, which are annuals, and called simply Hawk-weed, but should be Bastard Hawk-weed.

The species of our gardens are,

¹CREPIS *Rubra*.

Red flowering Bastard Hawkweed.] Crepis with spear-shaped, jagged, radical leaves, spreading on the ground; between them the flower-stalk, dividing into many erect branches a foot and half high, having oblong, lyre-shaped, amplexical leaves, and every branch crowned by a large, red, compound flower.

²CREPIS *Barbata*.

Barbated Yellow Bastard Hawkweed] Crepis with long, spear-shaped, indented, radical leaves; between them the flower-stalk, dividing into erect branches a foot and half high, garnished with small, spear-shaped, close-fitting leaves; and all the branches terminated by compound yellow flowers, with dark purple middles, having the involucre longer than the calix, squamous and bristly.

Varieties of this.] With deep yellow flowers—with sulphur-coloured flowers—both sorts having dark purple discs.

The flowers of all the sorts are large, compound, of many flat florets spread over one another imbricated, and, when fully blown, appear like a radiated flower, appearing in June, July, and August, extremely conspicuous and beautiful, and are succeeded by plenty of seed, from which, if permitted to scatter on the ground, many plants will rise without trouble.

These plants are pretty ornaments to the borders and other compartments of the pleasure-ground, and they grow freely in any common soil of a garden.

Propagation, &c.

The plants being annual, they must be raised annually from seed, which may be sown

sown either in autumn or spring; the rule is, that by sowing in autumn, i. e. in August or September, the plants come up the same season, stand the winter, and flower in May, June, and July; those sown in spring flower in July, August, September, and October.

At either of these seasons of sowing, it is proper to sow them at once in the places where you design them to flower; therefore, in different parts of the borders, in patches at five, ten, or fifteen feet distance, sow the seeds, five or six in a patch, half an inch deep, placing sticks for marks; and when the plants are two or three inches high, thin them to three or four in each hole or patch. See HARDY ANNUALS.

CRESCENTIA, Calabash-tree.

It furnishes one species of the tree kind, admitting of several varieties, all of the West-Indies, &c. and retained here in our stoves for variety; derives its name from its fruit, called Calabash, which is sometimes as large as a man's head.

Class and order, *Didynamia Angiospermia*.

Characters.] CALIX is monophyllous, and divided into two roundish segments. COROLLA is monopetalous and irregular, having a curved gibbous tube, and erect limb, five-parted at the brim. STAMINA, two long and two short filaments, and incumbent didymous antheræ. PISTILLUM, a pedicellated germen, filiforme style, and capitated stigma. PERICARPIUM, a large, baccaceous, oval, or bottle-shaped fruit, with a thin hard shell, and many seeds.

The species is,

CRESCENTIA Cujete.

Common Crescentia, or Calabash-tree, formerly Cujete.] Crescentia with an upright, robust, whitish trunk, divided at top into a large, spreading, regular head, from ten to thirty feet high, garnished with large, oblong, entire leaves, and greenish yellow flowers on long foot-stalks from the sides of the branches, succeeded by large shell fruit of different forms and magnitude, in different varieties.

Varieties are] Crescentia with long spear-shaped leaves, narrow at both ends—with broad oval leaves—with large oval fruit—with small round fruit—bottle-shaped fruit.

These fruit are of different magnitudes, from the size of a good orange to that of a man's head, or larger, all of which fruit have a hard and thin shell, filled with pulp and seeds; the pulp is soft, sour, and unfavoury, and seldom eaten.

These trees in this country, being always retained in pots in our stoves, assume a shrub-like growth, and I believe very few, if any at all, have yet flowered in these parts.

In Jamaica, Barbadoes, and other parts of the West-Indies, the trees growing as large and spreading as an apple-tree, bear abundance of fruit, the shell of which, having the pulp scooped out, is as thin and light as brown paper, and some of the largest capable of holding six or eight pints of water, &c. and are chiefly used for liquor and eating utensils.

All the varieties are propagated by seeds procured from abroad in the shells; as soon as they arrive take out the seeds, and sow them in pots of light rich earth, and plunge them in a bark-bed; and when the plants are two or three inches high, plant them out in separate small pots, plunging them also in a hot-bed, or the bark-bed in the stove, where they must always remain, giving them the necessary care of other tender exotics.

CRINUM, Asphodel Lily.

This genus furnishes four beautiful flowery perennials of the tuberous and bulbous-rooted tribe for the green-house and stove, producing erect firm stalks two or three feet high, crowned each by a large umbellate cluster of spathaceous, monopetalous, long, funnel-shaped flowers; blue, white, &c.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, a diphyllous, oblong, spatha-like involucre, becomes dry and reflexed. COROLLA, monopetalous and funnel-shaped, having a long tube, the top deeply divided into six spear-shaped, concave, obtuse, reflexed segments. STAMINA, six very long filaments, and oblong incumbent antheræ. PISTILLUM, a germen in the bottom of the corolla, slender style, and trifid stigma. PERICARPIUM, a suboval, trilocular capsule, having seeds.

The species are,

¹CRINUM Africanum.

African Asphodel Lily, or Tuberous Hyacinth.] Crinum with a root composed of many tuberous fibres, collected into a head at top, crowned by spear-shaped, plane leaves, their bases embracing each other, and spread two ways; and from one side, round hollow flower-stalks two or three feet high, surmounted by a large umbellate cluster of bright blue flowers.

²CRINUM Asiaticum.

Asiatic Asphodel Lily.] Crinum with a large bulbous root, crowned by long carinated leaves, two

C R I

two or three feet in length, embracing at their base, and spread every way; and from one side, round hollow flower-stalks two or three feet high, terminated by large umbellate clusters of white odoriferous flowers, having very long tubes, and long segments much reflexed.

³CRINUM *Americanum*.

American Evergreen Asphodel Lily.] Crinum with a bulbous fleshy root, crowned by long, broad, plane leaves, embracing each other in their base; and flower-stalks two feet high, terminated by large, umbellate clusters of white odoriferous flowers, having broad segments, having the tops formed on the inside like finger-nails.

⁴CRINUM *Latifolium*.

Broad-leaved Asiatic Crinum.] Crinum with a large fleshy root, crowned by oval-lanceolate, plane, acuminate, close-fitting leaves, and flower-stalks two feet high, terminated by large umbellate clusters of white fragrant flowers, striped with purple.

The roots of all these plants are perennial; the stalks annual, round, thick, succulent, hollow, and universally crowned by a sort of spatha protruding the umbels of flowers, each separate flower formed of one long, tubular, six-parted petal, of great beauty, appearing at different times of the year, but more commonly in autumn, often continuing till spring, frequently succeeded by capsules, especially the bulbous sorts, in which are produced small bulbs, which, planted, become proper plants.

The first sort is for the green-house, and the other three for the stove, retaining them always in pots of rich light earth, observing to shift them every year after flowering, for the sake of fresh earth, and separating the off-sets, giving occasional waterings summer and winter.

Propagation.

The first sort is propagated by off-sets from the sides of the main roots the end of June and July, turning them out of the pots, and so either slip or cut off the off-sets, as you see occasion, planting each off-set in a pot of light rich earth, and place them in the shade five or six weeks, giving water, and they will probably flower the following September, which, toward the end of October, place in the green-house for the winter.

The second, third, and fourth sorts, are propagated by the off-sets of their roots, or by the small caulin bulbs of their capsules;

C R O

but the root off-sets flower soonest, planting them in pots of rich earth, and plunge them in the bark-bed of the stove until they begin to flower, when they may either be placed upon the shelves, or permitted to remain in the bed, as convenient.

It is proper to shift or transplant the roots of all the sorts every year or two, at their period of rest, for the sake of fresh earth, and separating the off-sets.

CRITHMUM, Samphire.

The plants are hardy, herbaceous, succulent perennials, both esculents, and for variety, rising two feet high, terminated by yellow umbels.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, umbelliferous flowers, having a many-leaved general involucre. COROLLA, a uniform general umbel, the florets of five petals. STAMINA, five filaments, and roundish antheræ. PISTILLUM, a germen under each floret, two styles, and reflexed stigmas. PERICARPIUM none. SEMINA, a compressed two-parted fruit, and two seeds.

The species are two, but the principal one is,

CRITHMUM *Maritimum*.

Common Maritime Samphire.] Crithmum with a fibrous penetrating root; thick, succulent, branchy stalks, two feet high; winged fleshy leaves, of many small, spear-shaped, fleshy lobes; and round yellow umbels of flowers at the top of the stalk and branches.

The plants grow naturally on the sea-coasts among the gravel and rocks; its leaves are an excellent pickle, used for sauces, and are by many eaten raw in sallads, is of a saltish relish, palatable, and comfortable to the stomach, and is brought by the simplers in great plenty to the London markets.

To propagate this plant in gardens, either as an esculent, or for variety, sow the seeds in some gravelly, sandy, or rocky situation, half an inch deep; the plants will come up, and endure many years.

They may also be increased by parting the roots.

CROCUS, Saffron, but commonly called *Crocus*.

The plants are very low, flowery, ornamental perennials, of the bulbous-rooted tribe, valuable for ornamenting the fronts of our borders at early spring and late in autumn; for there are vernal and autumnal sorts, of each many varieties, all of which are acaulis, so that the flowers and leaves rise directly from

from the root, attaining only from about three to five or six inches high.

Class and order, *Triandria Monogynia*.

Characters.] CALIX, a monophyllous spathe. COROLLA is monopetalous, with a long erect tube, and the limb deeply divided into six equal, oblong, erect segments. STAMINA, three filaments shorter than the corolla, and arrow-pointed antheræ. PISTILLUM, a roundish germen under the corolla, slender style, and three twisted stigmas. PERICARPIMUM, a roundish, trilobate, trilocular capsule, containing roundish seeds.

Modern botanists admit of but one real species of *Crocus*, which however comprehends many beautiful varieties, and the following description of the original species serve for all, in respect both of the root, manner of growth, mode of flowering, general habit, and stature of the plants; only sometimes by culture, the bulbs will encrease in magnitude, the leaves in breadth, and the flowers larger; so that the main difference of the numerous varieties is in the colourings of the flower, and the times of flowering, spring and autumn; observing, that although the autumnal *Crocus* is probably the original varieties, the spring *Crocuses* are considerably the most numerous.

They may be divided into two classes, the autumnal and spring flowering.

The species is,

Crocus Sativa.

Cultivated Saffron, or Crocus.] *Crocus* with a small, roundish, brown, bulbous root, compressed at bottom; and directly from the root issue many long, narrow, deep-green leaves; and amidst them the flowers, all protruded from a thin, univalvular, radical spathe; the tube of the flower long, standing on the root, and serving as a foot-stalk to the limb or upper part, which is erect, six-parted, widens gradually upward, and grows from about three to five or six inches high.

Varieties of the *Crocus Autumnalis* are as follow: the first of which is the original *Crocus*, or Saffron.

Saffron Crocus (Crocus Officinalis)—A long-tubed blueish-purple flower, having its three stigmata of a fine reddish-golden colour; which part is the officinal Saffron: hence the name.

Autumnal small blue *Crocus*—deep blue—sky-blue—whitish-blue—many-flowered whitish-blue—purple—large rush-leaved purple—and autumnal white *Crocus*—autumnal yellow *Crocus*.

All these varieties of *Crocus Autumnalis* flower about the beginning of October, but never furnish seeds here; they are very beautiful in patches in the fronts of borders, or in beds by themselves, and very proper autumnal ornaments for gardens of every extent, as coming into full bloom at a season when most other flowers are on the decay; and they grow freely in any common soil, and, although they produce no seeds in England, they encrease in tolerable plenty by off sets of the roots.

The flowers of these commonly appear before the leaves, which, when the flowers fade, continue their growth, remain all winter, and decay in May following, when is the time to remove the roots, which should be every two or three years.

Varieties of Vernal or Spring *Crocus* are,
Yellows.] Small yellow *Crocus*—large yellow *Crocus*—golden-yellow *Crocus*—yellow black-striped cloth of gold *Crocus*—yellow purple-striped *Crocus*—double cloth of gold *Crocus*.

Whites.] White *Crocus*—white purple-striped *Crocus*—white purple-bottom *Crocus*—white black-striped Scotch *Crocus*—whitish cream-coloured *Crocus*—whitish ash-coloured *Crocus*—little narrow-leaved white *Crocus*—white blue-striped *Crocus*.

Blues.] Small blue *Crocus*—large deep blue *Crocus*—blue purple-striped *Crocus*—blue violet-striped *Crocus*—pale-blue purple-bottom *Crocus*.

Purples.] Small purple *Crocus*—large purple *Crocus*—striped purple *Crocus*.

Polyanthus Crocus—having many purple-violet white-striped flowers.

All these beautiful varieties of *Crocus Vernalis* flower in February, March, and April, and ripen seeds in May; they are all very ornamental spring flowers, and valuable for their early appearance, when very few other flowers are to be seen, and are so hardy, that they will grow almost any where, and rear their flowery heads even when chilling colds prevail, and, where duly disposed along the fronts of borders or clumps, make a fine shew a month or six weeks; and they encrease abundantly by off-sets of their roots, as well as furnish seed for raising new varieties.

The flowers and leaves of all these spring varieties generally rise nearly together, though the flowers rather appear first; the leaves continue their growth till May or June, when they wither, and this is the time to remove the roots.

roots, which is necessary every two or three years, to separate the numerous off-sets. See **BULBOUS ROOTS**.

Planting, Culture, Propagation, &c.

In respect to the planting and culture of all the varieties, both of the autumnal and vernal Crocus, for ornament in gardens, they may all be planted in any of the common borders, &c. without any other preparation than common digging, and a blunt-ended dibble is to be used in planting: the following is the general management of both the classes of varieties, i. e. autumnal and spring-flowering.

Autumnal Crocuses — These varieties may either be planted in beds by themselves, in rows nine inches distance, or in patches along the fronts of borders, as directed for the spring Crocuses.

The bulbs for planting may be had of all the nurserymen for two or three shillings per hundred.

The best season to plant them is in July or August, observing, in either of the above methods of planting, to set the roots about two inches deep; they will flower in October following, and continue to flower annually at the same season, observing, they may remain undisturbed three years, when it is proper to take them all up, to separate the small off-sets, and fresh dig the ground, &c. which should be done in June, selecting the largest and roundest roots, to plant for the future bloom; these should be planted again early in August, that they may blow in due perfection the following October.

Their general propagation is by off-sets, as above; and from a few bulbs of each sort you will soon have plenty, by means of an annual encrease.

Vernal or spring Crocuses. — These are often planted in a single row close along the edges of beds or borders; but to have them effect as great a variety, and as grand a shew, as possible, I would advise planting them in patches of different-coloured varieties alternately, both along the front of the borders, and towards the middle, or in the fronts of shrubby clumps; so in patches of five or six inches diameter, plant five, six, or eight roots; and the distance of the patches may be, for those in the front, from eighteen inches to three feet distance, and those towards the middle of the borders should be at the distance of five or six feet, and, in general, about two inches deep.

The bulbs of all the varieties are sold by the nurserymen and seedsmen, from ninepence to three shillings per hundred, according to the sorts; or a hundred, including some of every sort, for three shillings.

The season for planting them is September, October, and November, though it may be performed, any time in open weather, from September to February; observing, however, those planted before Christmas flower considerably the strongest, observing the method of planting above directed.

The roots may remain two or three years without being removed, though, as the roots in that time will be encreased by their off-sets into large bunches, it is proper to take them up to separate them; the proper time is May or June, when the leaves wither, observing to separate the large from the smaller; and after being dried and cleaned, put them up till the planting season, as above-mentioned, when the larger ones are to be planted in the borders, as before, and the small ones, if wanted, may be planted in a bed, in rows six inches asunder, to remain a year or two to grow larger, when they will be fit for your borders, or for sale.

The propagation of all the tribe of spring Crocuses are effected plentifully by off-sets, as above observed; and from a few bulbs of each variety, you may in two or three years have a large encrease; and those who incline to try for new varieties may have recourse to seed, as directed for *Colchicums*.

In most gardens it is customary to cut off the long green leaves of the Crocus soon after the flowers decay, but this is injurious to the growth of the bulbs, and is done principally because the leaves, becoming long and straggling, have a littering appearance at the edge of the borders; but if this appearance could be dispensed with, and the leaves permitted to remain till they wither, it will nourish and prove beneficial to the roots, as will be obvious in their future bloom.

CRUCIFORMIS Flos, a Cruciforme, or Cross-shaped Flower; a flower composed of four equal petals, which spread at top on their claws four different ways, in form of a cross; stock-gilliflower, rocket, candy-tuft, lady's-smock, and honesty, furnish examples.

CUCUMIS, Cucumber, and the *Cucumis Melo*, the Melon.

The Cucumber and Melon, though vastly different in the external habit of their fruit, the characters of their flowers are exactly the same;

same; so the plants are consequently both species of the genus *Cucumis*, very tender annuals of trailing growth, valuable for their most excellent fruit.

Class and order, *Monoecia Syngenesia*.

Characters.] CALIX, male and female flowers apart on the same plant, having each a monophyllous bell-shaped cup, terminated by five awl-shaped bristles. COROLLA, is in both sexes monopetalous, bell-shaped, divided into five oval rough segments, and adheres to the calix. STAMINA, in the males, three very short connivent filaments inserted into the calix, two of them bifid at top, and narrow antheræ, creeping upward and downward, adhering to the outside. PISTILLUM, in the females, an oblong germen under the corolla, very short style, crowned by three thick, gibbous, tripartite stigmas. PERICARPIUM, a fleshy, oblong, trilocular fruit, and numerous, oval, acute, compressed seeds.

The Cucumber and Melon have, by most authors heretofore, been treated as distinct genera; but the Linnæan system determines them to be of the same genus, and in which we must therefore also range them, though, for distinction sake, under two separate heads; first, the Cucumber, *Cucumis Sativa*; second, the Melon, *Cucumis Melo*.

First Head.

Cucumis Sativa, or Garden Cucumber.

Of the Cucumber there is but one real species, but of which are several curious and valuable varieties of the fruit; and as to the plants, they are herbaceous trailing annuals and exotics of most delicate tender tempera-
ture, unable to endure the open air here, except about three or four months in the heat of summer; and to raise them in early perfection, requires the aid of substantial hot-beds, under frames and glasses; and the culture of them, at an early time, being esteemed a most curious branch of gardening, it excites an ambition in most gardeners to excel each other in their production as early in the spring as possible.

The species is,

CUCUMIS SATIVA.

Cultivated, or Common Cucumber.] *Cucumis* with roots composed of numerous, long, slender, white fibres; long slender stalks, very branchy at their joints, trailing on the ground, or climb by their clasps, adorned at every joint by large angular leaves, on long erect foot-stalks; and numerous, monopetalous,

bell-shaped, five-parted, yellow male and female flowers, at the same, or different joints, the females succeeded by oblong rough fruit.

Varieties are as follow:

Common Rough Green Prickly Cucumber—A middle-sized fruit about six or seven inches long, having a dark-green rough rind, closely set with very small prickles; the plant is of the hardiest sort, bears plentifully in summer, but does not show fruit early, so is not proper for frames.

Short Green Prickly Cucumber—A short fruit three or four inches long, the rind rather smooth, and set with small black prickles; is valuable principally for being one of the hardiest and early sorts; that is, as to early, the plants frequently begin to shew fruit at the first, second, or third joint, whereby we may expect fruit in perfection much sooner than from such plants that do not shew fruit till they advance several joints in length.

Long Green Prickly Cucumber—A long handsome fruit, from about six to eight or nine inches long, rather thinly set with prickles; the plants are remarkably good bearers, and as there is an early and late sort, it is considerably the best variety of Cucumber for the main crops, both in the frames and hand-glass, as well as in the open ground for picklers.—Variety of this with white fruit.

Early Green Cluster Cucumber—A shortish fruit, remarkable for growing in clusters, and appearing early.

Long Smooth Green Turkey Cucumber—The plants are strong growers, with very large leaves, and long, smooth, green-rinded fruit, without prickles, obtaining from ten to fifteen inches in length.

Long Smooth White Turkey Cucumber—The plant a strong grower, and smooth-rinded fruit, without prickles, from ten to fifteen inches long.

Large Smooth Green Roman Cucumber—A strong growing plant, and very large, long, smooth, green fruit.

Long White Prickly Dutch Cucumber—A white fruit, eight or ten inches long, set with small black prickles; the plants but bad bearers in England.

Of the above varieties, the first four are considerably the best bearers in this country, and the only sorts to be depended on, both for the early and main crops, and the Long Green Prickly sort most of all; the last four varieties being, for the general part, but indifferent bearers, are improper to be employed

either for an early, or any general summer crop; but as the fruit is singularly large and beautiful, a few plants of each sort should be admitted in the summer crops, under the hand-glasses, &c. or in the common ground, among the late crops.

All the above sorts, though only varieties, yet by care in raising each respective sort in separate beds, or so as the farina of the flowers of the different sorts may not impregnate each other, they will continue tolerably permanent; but without this care they in time will vary to one another.

The flowers of all the varieties of *Cucumis* are monoecious, i. e. male and female apart on the same plant, either at different joints, or both arising at the same joint; the male flowers are those commonly, but erroneously, called, false blossoms, and are often pulled off; but they are so far from being false or useless, that without their vicinity and assistance, no fruit can be expected; for they contain upon their antheræ the *pollen*, or fecundating golden powder, so essentially necessary for the impregnating the ovary of the female flower, by which only the fruit sets, swells to maturity, and produces fertile seeds: both male and female flowers are distinctly obvious, both before and after they open; the male flower stands immediately upon the top of its foot-stalk, without any appearance of germen or fruit under it; the female flower discovers the germen or embryo fruit immediately under its base, so that the flower sits close upon the top of the fruit, as is apparent even from its first issuing from the branch, when not so big as a very small barley-corn: from the first appearance of the miniature fruit till its maturity, i. e. fit to cut for the table, it takes up generally from about eighteen to one-and-twenty days growth.

Cucumbers at an early season are highly valued, and are esteemed almost the greatest rarity of a garden; principally, because the plants being of so extremely tender and delicate nature, as to require considerably more attention and skill in their early culture than any other esculent of our kitchen-garden collection, except the Melon, which is nearly of the same temperature, and both of which, in the article of hot-bed culture, afford opportunities for a gardener to display his abilities, and raise his reputation, as eminent in his profession.

What is to be understood by early Cucumbers, is principally such that arrive to per-

fection in February, March, and April, and is performed by hot-beds, under frames and glasses, begun about Christmas; though, to have Cucumbers in May, June, and July, the aid of hot-beds and glasses are also requisite, made at, or from about Candlemas till May; but in the beginning of June, when the weather becomes warm and settled, the seeds will grow in the full ground, and the plants will bear the full air till the end of September, after which time the cold nights soon destroy them; so that if the fruit is required after that time, the plants must be protected by frames, &c.

Observations on their General Culture.

As to the propagation of Cucumbers, the plants being annual, must of course be raised every year from seed, and the season and order of sowing is, either in hot beds, any time from about Christmas till May, or in the full ground in the latter end of May, or beginning of June, observing, that, as the plants rarely succeed in the open air before June, all intended to be raised before that time require more or less artificial heat, and shelter of frames, glasses, &c.

By artificial heat in the culture of these plants, may be comprehended not only that of dung hot-beds, the most common method, under common garden-frames and lights, hand or bell-glasses, &c. but also that of stoves, effected by bark-bed heat and actual fire; and in which departments the plants may be raised at almost any season: dung hot-beds, however, under frames, &c. are the most successful, and best for any general early crop; but we shall exhibit both methods in their proper place.

The particulars to be materially observed, relative to the times of sowing and having Cucumbers for use, is; to have Cucumbers early, i. e. in perfection in March and April, it is performed by hot-beds, under frame and glasses, begun about Christmas, or between that and Candlemas; or to have them come in for use in May, the same aid is also requisite, beginning in February or March; and even when they are not required till June and July, the aid of moderate hot-beds are likewise necessary, made in April, or beginning or middle of May, either under frames, or hand or bell-glasses, or those made in May might be covered with paper lights, in default of others; but for late crops, to come into use in August and September, no artificial

ficial heat nor covering is necessary, as, in the end of May, or beginning of June, when the weather is become settled and warm, the seed may be sown in the full ground, and the plants will come up, and attain a bearing state in two months; but to have Cucumbers from the earliest to the latest period, some endeavour to have them fit to cut about Christmas, by beginning with a moderate hot-bed in October; and some are ambitious of having them for the table the year round, so continue sowing every month in the year: it is, indeed, often easier to have Cucumbers at Christmas, than a month or two later; and it is much easier to have them in April and May, than in February or March, and less dung for hot-beds, as well as less attendance, is required: however, to have good general crops from spring till autumn, three different principal crops are generally raised at three different times, from about Christmas or Candlemas till June; the first, or earliest, to be in hot-beds, under frames and glass lights; the second, or middle crop, also in hot-beds, under hand or bell-glasses, &c. and the third, or latest crop, is in the common ground; each of which crops is exhibited separately.

By the above hints you will readily judge of the time to begin Cucumber-framing, according to the times the Cucumbers are required for use, or according to your convenience in respect to frames, glasses, dung for hot beds, mould or earth, &c. for unless you are properly accommodated with these materials, you should never attempt having Cucumbers very early; for, as above hinted, it is much easier to have them in April, May, and June, than in February and March.

The principal materials necessary in the early culture of these plants in dung hot beds, under frames and glasses, &c. are as follow.

For the early crops, frames and lights of two or three different sizes, for the same number of different hot-beds; that is, a small frame of one light for the seed-bed, another of larger dimensions, or a two-light one, for the pricking-out or nursery-bed, and one or more two-light, or three-light-frames, for the final or fruiting hot-bed; each frame furnished with glass lights perfectly wind and water-tight. See FRAMES.

For the middle crops, for hot-beds made in April and May, hand-glasses, either the square ones laid in lead, or bell-glasses, or, in default of these, oiled paper frames. See HAND-GLASSES.

Horse stable-dung for making the hot-beds is a principal article; procure such that is fresh, full of heat, neither too long and strawy, nor too short, but a due mixture of both; one cart-load, or twelve or fifteen wheel-barrows full to each light, or about thirty or forty to each three-light frame, making an allowance also of a due portion for occasional linings; all of which ought to be previously prepared by casting it up in an heap about a week, or ten or twelve days, to forward the whole to an equal and regular fermentation, and that the violent burning quality, rank steam, and unwholesome stench may evaporate; and if turned over once or twice, it will be more effectually prepared. See HOT-BEDS.

Earth for moulding the beds.—This should be very rich, moderately light and dry, having been previously prepared some months in a compost heap, see COMPOST; or good light kitchen-garden earth, enriched with rotten dung of old hot-beds, is a proper soil, and, if blended with a moderate portion of fine, light, fresh loam, properly incorporated, it will invigorate its vegetative quality, preparing the whole in an heap, as above, three or four months, at least, before using it; likewise observing, that before using the mould for the hot-beds, a due quantity should be wheeled into a dry covered shed, open to the sun and free air, to be defended for a fortnight or three weeks, to have it of a moderately dry temperament, which is most necessary in early framing; and, when the mould is to be used, it is not advisable to screen it, only clear out large stones, and break the clods as small as possible with the spade, as sifting or screening would render it too compact for the tender fibres; besides it is apt to bind, and by lying too close to confine the steam, is more apt to burn at bottom, by the heat of the dung of the hot-bed.

Mats of bafs, reeds, or straw, are necessary for covering the glasses of the hot-bed on nights, and all bad weather; but bafs mats are the most convenient and effectual covering. See MATS.

Small pots (thirty-two's and forty-eight's) are also necessary in early Cucumber culture, both for sowing the seed in occasionally, and for pricking the seedling plants in, three or four in each pot, whereby the plants may be occasionally removed in pots, if necessary, from one hot-bed to another, to forward them; and also be more readily transplanted for good into the fruiting hot-bed, with the whole ball

ball of earth of each pot about their roots, so as not to feel their removal; and each pot of plants serves for one light, that is, three pots for a three-light frame.

As to the situation proper for the early culture of these plants in hot-beds, chuse a place that fronts the south, and is open to the whole day's sun; and, if possible, where the ground is dry, or, at least, where water is not apt to stand; if of a gentle declivity the better, and if enclosed, either wholly, or on the north, and east, and west sides, with a reed hedge or paling, to break the winds, it will be a particular advantage.

Dig no trench, as often practised, wherein to make the bed, especially in early work, but make it entirely on the surface of the ground, being proper both to preserve the bottom from being chilled by standing water, and that the whole of the bed, from the very bottom, may receive the benefit of linings. If the ground is wet, or water apt to stand in winter, I would advise rather to raise the part gradually higher than the general level, that the moisture, or falling water, may run away from the bed.

For the latter crops, raised in the open ground in June, nothing more is necessary than sowing the seed half an inch deep in a rich soil; the plants will come up, and bear plentifully in August and September.

With respect to seed; in the choice of this for early crops, you will of course procure that of the early short or long prickly sorts; the latter is best for any general crop; and if you save the seed yourself, it is of importance to save it from some of the earliest fruit, that appear at the first, second, and third joint of the main runner; and this seed, if possible, should be, at least, two years old before you sow it, but if three or four the better, because plants raised from new seed are apt to fly luxuriantly into vine, without shewing fruit in any reasonable time, so are consequently improper for early work; but if you are necessarily obliged to use new seed, endeavour to prepare it, by keeping it three or four weeks in your breeches pocket, previous to the time of sowing, the drying heat of which will divest it of part of its luxuriant quality.

We now proceed to the culture of the different crops; and as the early culture, in hot-beds, of these plants and Melons, requires the gardener's attention more than that of most other plants, we will enlarge on that

article, so as to exhibit the whole process according to real practice.

Their early Culture in Frames in the Seed and Nursery-bed.

The time to begin the culture of early Cucumbers in frames is to be according to the foregoing observations, but some time between Christmas and Candlemas is the most common season to begin that work.

In the culture of early Cucumbers, it is proper, where there are good accommodation of frames and hot dung, to forward the first crop in three different hot-beds; a small one for a one-light frame, in which to sow the seed, and raise the plants a few days old; a second, of larger dimensions, for a large one-light, or a two light frame, by way of nursery-bed, in which to prick the plants from the seed-bed into pots, to remain three weeks or a month, till their two first rough leaves are two or three inches broad, and when the plants have formed one joint; then to be transplanted with the balls of earth about their roots into a third and final hot-bed, to remain to fruit; the planting in this last bed gardeners call ridging out; however, if the seed-bed is made substantial for a large one-light, or a moderate two-light frame, it is very possible, by aid of occasional linings, both to raise the plants, prick them down, and continue them in the same bed till large enough for the fruiting hot-bed.

Proceed therefore to prepare the seed hot-bed according to the above rules, procuring for this purpose hot dung, in quantity, quality, and preparation, as before directed; which being ready, then, with four stakes, set out on the ground the proper dimensions of the bed, according to that of the frame, allowing for the bed to be rather two or three inches wider on every side: begin the bed by laying some of the longest dung in the bottom, afterwards take it as it comes to hand, mixing the short and long well together, and spread it regularly on the bed, beating it firmly down with the fork as you go on, till raised to the proper height; observing, if you intend it only just to raise the plants, two feet and a half is high enough; but if designed both to raise and forward the plants large enough for the fruiting-bed, it is proper to make it three feet six inches high at least; or, if the dung consists of very long litter, four feet height in dung is not too much, since it will settle almost a foot in a week's time. See HOT-BEDS.

As

As soon as the bed is made, set on the frame and glass, keeping it close a day or two to draw up the heat; then tilt the light behind, for the steam to pass off.

In six, eight, or ten days, according to the substance of the bed, the vehement heat will begin to abate, when you may earth the bed with the prepared mould, before-mentioned, five or six inches thick; and next, or the same day, as soon as the earth is warm, sow the seed, drilling it in near half an inch deep.

But if you are in haste to forward your plants as much as possible, or that you would use only one hot-bed both for the seed and nursery-bed, let the bed be made substantial, as before observed, for the largest one-light, or for a two-light frame, according to the quantity of plants required; so that by sowing the seed in small pots (thirty-two's) you may use the bed the same, or next day after it is made, as soon as it begins to heat, covering it all over with any sort of dry earth, or with old tan five or six inches thick, filling some pots with rich mould, and plunge them a little in the earth, &c. and next day the earth in them being warm, sow fifteen or twenty seeds in each; but observing, if there is danger of burning, draw up the pots more or less in proportion, as you see it necessary, to prevent the earth, &c. from being burned; and in about a week the plants will be up and fit to prick in pots, and by which time the bed will be arrived at a moderate heat.

The seed however being sowed in either method, do not omit tilting the light behind an inch or two occasionally, to pass off the steam, and cover it on nights with a mat.

Thus the plants will come up in three or four days, observing now to admit fresh air daily, by raising the lights an inch or two behind, also occasionally on nights, according to the rules hereafter directed, and cover every night with mats: when their cotyledons, or seed-leaves, are fully out of the earth, and begin to expand about half an inch in breadth, it is proper to prick them in pots (forty-eights) previously filled with rich earth within an inch of their rims, and placed in the frame a day before to warm, either in the same bed, made substantial at first for that purpose, otherwise in a new hot-bed, as you shall judge necessary, prepared a week before, and earthed, or covered with old tan six inches deep, for the reception of the pots: in either of these beds, when the earth of the pots is warm, proceed to prick the plants therein, raising them carefully out of the seed-bed, &c. with the fibres of their

roots entire; then forming a hollow in the middle of the earth in the pots, place three or four plants horizontally at equal distances in each pot, covering over their shanks almost to their seed-leaves, shaking the pot gently to settle the earth close; if the earth is dry give a very light watering with such that has stood a few hours in the bed in bottles, to take off the chill; then directly plunge the pots to their rims in the earth of the bed, being careful that every part of the dung within the frame is covered with earth, &c. to restrain the steam from rising immediately from the dung upon the plants; for the rank dung steam, when not meliorated by first passing through the earth, would prove their destruction.

In two or three days, at most, they will have taken fresh root, and begin to advance in growth, though that is often effected by these plants in less than four and twenty hours, particularly when pricked out at the above age; nor will they then require shading from the sun till rooted, as is often the case with larger plants.

The plants being thus potted out, continue every day to tilt the lights, to pass off the steam, and to admit a moderate portion of fresh air, and every night cover the glasses with a mat or two; give also occasional light waterings, and as the plants rise in height, mould up their shanks by degrees; likewise support a due degree of heat in the bed, and in about a month the plants will be arrived at a proper size for ridging out.

As in the early culture of Cucumbers, the plants being tender, are liable to suffer by many accidents; it is therefore eligible to continue sowing a little seed in the same bed every week, and prick some in pots, as before directed, that, if the preceding plants should fail, these may stand, and will be a ready substitute; or, if the whole should stand, these will do for latter crops, and you will have some to oblige a friend.

But as to the particular culture of these plants, after being potted in this their nursery hot-bed, the following are the principal directions.

During the violent heat and steam of the bed, care is necessary to tilt the upper end of the lights, not only every day, but also occasionally on nights, raising them an inch or two, or a little more or less, in proportion to the temperature of the bed and weather, both that the steam may freely evaporate, as well as for the admission of fresh air, to strengthen the plants, which would otherwise draw

draw up weak and yellow-coloured; but tilt the glasses, however, less in proportion on nights than the day, observing, in all cold piercing weather, to screen the opening or tilted part of the lights occasionally, by hanging a mat loosely from the top of the glasses, which will break the keen edge of the air and winds from rushing immediately upon the tender plants; likewise observe, that if the first great heat is so violent as to endanger burning the earth in the pots, the roots, or fibres of the plants, which you ought to examine daily; the remedy is, to raise up the pots a few inches, or as high from the dung as shall appear expedient for the preservation of the plants; and when the vehemence of the heat subsides, they may be plunged again to their rims, observing also, when the heat is moderate, to raise the glass for the admission of air, &c. only occasionally in the day time, from about nine or ten in the morning in winter and early spring months, till two, three, or four in the evening, according to the heat of the bed, and as the weather is more or less mild and sunny, always shutting down the glasses close before sun-set; cover the lights with mats every evening about four or five o'clock, or a little sooner or later, according to the earliness, or advanced period of the season and temperature of your bed, &c. uncover each morning about eight, or a little sooner or later, according to the above rules, observing, that during the first greatest heat of the bed, a single mat thick is sufficient covering; but as the heat decreases, augment it to two or three, but never let the ends of the mats hang down considerably over the sides of the frame and bed, which would draw up a violent steam, and promote burning, and, at any rate, would stifle the plants, draw them up weak, and occasion them to assume a yellow hue.

Water in moderate sprinklings may be necessary once in three, four, five, or six days, as you shall see occasion, by the mould drying in the pots, and according to the heat of the bed, and as the weather is more or less sunny; observing, that sunny days are to be preferred for the application of this element, and during the winter and early spring months, from about eleven to one or two o'clock is the proper time of day to perform the work; the water for which purpose should be soft, i. e. either pond, river, or rain-water, and should either be previously placed in bottles within the frame of the hot-bed a few hours, just to

take the chill off, or prepared to a proper temperature, by warming a little over a fire to mix with the rest, but by no means let it be warmer than just to take off the chill.

According as the shanks of the young plants rise in height, add a small portion of fine dry earth round them, repeating it occasionally till the vacant space in the top of the pot is filled, being careful to have some fine rich earth in the frame to warm for this use, adding it by degrees, and the plants will emit roots all the way along their shanks, as far as they are thus landed up, which will prove of no inconsiderable advantage to their growth.

In regard to the heat of the bed, it must all along be preserved in a due temperature by proper linings round its sides. But, in the first place, that in a week after the bed is made, when the vehement heat abates, it is proper to lay some dry straw, waste hay, or dry fern, around the sides, near a foot wide, and as high as the bed, and a little way up the frame, which will prevent driving wet, and piercing cold winds from penetrating, to chill and occasion a sudden decay of its heat.

But when the heat begins naturally to decline, which in a small bed often happens in about a fortnight, or three weeks, after it is made, then the straw, &c. must be removed from the back and front of the bed, substituting in its stead a lining of well-prepared hot dung, working it about eighteen inches wide at bottom, sloping it gradually upward, and raise it three or four inches higher than the dung of the bed, to allow for settling, covering the top with two inches depth of earth close up to the sides of the frame, to keep down the steam, which might enter the frame, when the glass is opened to give air, and injure the plants; for all rank steam, coming directly from the dung upon these plants, will scald and destroy all the leaves it encounters in its direction: this dung lining will revive the declining heat of the bed, and continue your plants in a healthful growing state. In ten or twelve days after, you may line the other sides of the bed, if it shall seem necessary, otherwise defer it longer; and if the season should prove very wet or snowy, lay some dry litter around the frame, upon the top of the lining, to shoot off the water.

In the course of lining the bed, have a watchful eye against burning or steaming your plants, as a fresh dung lining often promotes a new violent heat and steam; you must therefore observe the precautions above hinted,

hinted, of raising up the pots of plants, if necessary, and tilting the light in proportion.

As the plants, when first potted out, consisted only of the two seed-leaves, or cotyledons, they, in a week after, will begin to push from their centre the first proper or rough leaf, and in a few days after that, the second rough leaf will advance, enclosing in its bosom other younger leaves, and the end of the first advancing shoot or runner, which in a few days should be stopped, to strengthen the plants, and promote lateral fruitful shoots.

The operation of stopping should be performed when the second of the rough leaves has expanded the breadth of a shilling; it is a sort of pruning performed by taking off the end of the first runner, arising, as above hinted, in the bosom of the second leaf; is requisite both to strengthen the plants, and to promote their putting forth lateral shoots or runners, to fill the bed with proper-bearing vine; for the lateral shoots are the only bearers to be depended on: let therefore the end of the advancing runner be carefully taken off almost close to the base of the second leaf, but never suffer more than the third rough leaf to advance before this is done, and, if performed when the end of the shoot is not bigger than a large pin's head, the better; and by this early stopping the plants at the first or second joint, they will grow robust, and soon prepare to send forth fruitful runners, shewing fruit probably at the first or second joint; but if the first shoot was not stopped as above, it would sometimes advance two or three feet in length, without either sending forth side runners, or shewing fruit; for the fruit are always principally to be expected from the lateral runners.

Ridging them out in Frames.

When the plants have two or three rough leaves near three inches broad, and the operation of stopping at the first joint has been performed, as above directed, they will be in excellent order for ridging out, as they will then be just preparing to emit runners.

Provide therefore, in due time, dung for making the fruiting hot-bed, the quantity proportioned to the number of lights which you intend to work, allowing, if early, a cart load, or twelve or fifteen barrows full to each light; on this occasion your care is requisite to have it of proper quality, as before observed, by mixing it well together in an heap, see **HOT-BEDS**; but in your proceedings you

must with forecast make the necessary allowance for the time of the dung's working, and the bed coming to a proper heat, that the plants, when ready, may not wait for the bed; this premised, and the dung being prepared, stake out the bed frontways to the south, the width and length in proportion to the dimensions of the frames, and number of lights to be employed, making allowance for the bed to be six inches wider than the frames; and, when more than one range of hot-beds are intended, one before another, allow a space of five or six feet between bed and bed, for lining, &c. the dimensions being thus staked out, wheel in the dung, and proceed to make the bed, first shaking some of the most strawey dung along the bottom, and then mixing long and short regularly together, carry on the bed evenly, building the sides straight and upright, the middle perfectly full, and form every part equally close and firm, by beating it evenly down with the fork from time to time as you advance, not treading it, unless the dung is very long and strawey indeed, raising the whole three feet six inches high, at least, if early in the year; otherwise a yard in height will be sufficient, especially if any considerable range for two, three, or more frames; but if for a three-light frame only, and made any time before April, make it the full height of three feet and half, before mentioned, as it will settle near a foot in less than a fortnight; observing, that of whatever substance the bed, always raise it rather highest behind, finishing the work by shovelling up all the short dung remaining round the bed at last, and lay it at top in a ridge along the middle, which, after the bed settles, may be levelled as you see occasion; for it will be a week, ten days, or a fortnight, according to its substance, before its heat is moderate enough for the plants.

But as soon as the bed is made, I advise to set on the frame and glasses, being necessary both to defend the bed from great rains, and to forward it sooner to a proper degree of heat for the reception of the plants; observing, when the heat rises, to prop up the lights, to give free vent to the steam, at the same time thrusting a long stick or two into the bed, that by pulling them out daily, and feeling the lower part, you can readily judge of the working of the bed, from its first heat, till it gradually encreases to its greatest height of vehemence, and thence till it becomes of a temperate degree, which, in a middling bed,

is sometimes effected in a week or ten days, but when of a more considerable range, for two, three, or more frames, it is often near a fortnight, and sometimes more, before the heat becomes temperate enough to receive the mould and plants, which must not be trusted in the bed while the heat is violent, i. e. so hot that you cannot readily bear your finger in it any considerable time; for it would both burn the earth and roots of the plants, and, if it even only burns the mould, the plants can never thrive; do not, however, suffer the heat to become too moderate before you put in the plants, for it is necessary there be a brisk heat to set them a-going at first.

When the bed, therefore, is become of due temperature, prepare to mould it, previously observing, that, as the bed generally settles unequally, it is proper, first to take off the frames, and level all inequalities, and smooth the surface with the back of the spade, and directly set on the frame for good; then, the better to secure the earth, immediately under each hill of plants, from burning, you may, where convenient, lay a stratum of pliable cow-dung, not too wet, on the surface of the bed, just under the centre of each light, about eighteen inches, or two feet diameter, and an inch and half thick, plastering it close and smooth; this done, proceed to mould or earth the bed. Let the earth be rich, light, and moderately dry, as formerly mentioned, then, under the centre of each light, upon the stratum of cow-dung, lay about three pecks, or near a bushel of this earth, forming each parcel into a sort of conical hillock ten or twelve inches high, at the same time covering the rest of the bed, between and round the hillocks, with the same sort of earth three inches thick; on each of these hillocks of earth you are to set one pot of plants, as hereafter directed, and the rest of the bed is to be afterwards moulded up by degrees to the height of the summit of each hillock.

The reason for forming the earth in hillocks is, that if the bed should discover any tendency to burning after the plants are ridged out, the vehemence of the heat and steam will more readily pass off between the little hills, than if the bed was at once earthed all over to its proper depth; besides, by forming it in hills, if the earth should be in danger of burning, by removing some around near the bottom, to reduce the substance of the heaps, the steam will more easily find

vent, and if the earth should unavoidably burn at the base of the hillocks, the burnt earth can be more easily removed, with less danger of disturbing the plants, and, at the same time, be replaced, with fresh mould; likewise, by this practice, you may venture to ridge out your plants two or three days, and in some beds, a week sooner than if the bed was to be at once fully earthed; and likewise, by adding fresh earth by degrees round the hills, it greatly encourages the fibres of the plants.

But to proceed to planting—The bed being earthed, as above directed, immediately put on the glasses close, and by next day the bed will have imparted a proper warmth to the mould for the reception of the plants; having directed them, in the nursery-bed, to be potted, three or four plants in each pot, allowing one pot of plants to each of the above hillocks of earth; but previous to transplanting, let each pot of plants be watered a few hours before, that the earth may adhere firmly in a ball about their roots; then, to turn them out of the pots, spread your hand on the surface of the mould, passing the shanks of the plants between your fingers, and turning the pot upside down, strike the edge gently on the frame, the plants will readily come out with the whole ball of earth entire; then, making a wide hole in the middle of the hill of earth, place the plants, with the entire ball about their roots, therein, drawing the earth close round, and about an inch over the top of the ball; and if the earth is moderately dry, give a little water that has the chill taken off, and, as soon as they are planted, shut down the glasses close, to draw up the heat, observing, if the sun should shine out, and it occasions the leaves of the plants to flag, indulge them with occasional shade; but, by care in transplanting them from the pots with the entire ball about their roots, they will scarce feel their removal, so as to shrink their leaves at the approach of the sun; if they, however, flag considerably, shade them with a thin mat, from ten to two o'clock, the first three or four days, or till they take root so firmly as to stand the sun without flagging.

The plants being now ridged out, great attention is necessary to allow them a daily and proportionable share of fresh air, by tilting up the lights occasionally; likewise to cover the glasses every night with mats; particular care is also requisite, at first, to guard against their

their being annoyed by too much heat or steam, and that they do not suffer by cold or want of heat; occasional waterings are also necessary in moderation; the moulding up the bed round the hillocks by degrees must also be duly attended to, stopping the plants once more, to procure a farther supply of fruitful runners, and, as the runners advance in length, train them at regular distances, together with the care of setting the early fruit; and the due temperature of heat of the bed to be preserved by proper linings, &c.

As to the article air; in this particular your care is to consider not only the state of the bed, but likewise the temperature of the weather, early or advanced period of the season, or if the sun shines, or the air be cloudy, wet, or foggy; and to proportion the admission of air accordingly; observing, that wet or foggy air, even, though mild, is more unfavourable to the growth of these plants than frost, provided it is accompanied with sunshine, and that you have proper heat in the bed, to maintain a warmth about the roots of the plants, and to warm the internal air of the frame almost equal to that of a hot-house; and, indeed, great care is necessary to preserve your bed always nearly to that temperature; for the plants are rather of a more tender quality than the pine: let air, however, be admitted daily at all opportunities, when the wind is still, by tilting the lights behind, from half an inch to two or three high, as your discretion shall direct, according to the rules laid down for the nursery-bed, making an allowance, as the season and warm weather advances, in the time of day, of beginning to open and shut down the lights; and be still persuaded to occasionally hang a mat over the tilted part of the lights in sharp weather, that the plants may at the same time receive a moderate share of air, and the steam pass off without injury; for if the cold air is too freely admitted at an early season, it will frequently destroy, or greatly injure the plants; and if the lights are kept too close, so as to confine and stagnate the steam, the danger will be equal, the plants will imbibe an infected air, and soon shew their sickness by the yellowness of their aspect: when there is a considerable heat and steam in the bed, air should always be admitted the most freely, even sometimes on nights in a small degree, as observed of the nursery-bed; and in sunny weather air is to be admitted more freely than in wet, foggy, or cloudy days: in the whole

observe, that as there are often several changes of weather in a winter's day, and even early in spring, your attention must be given accordingly, to admit either more or less air, or none at all, as you shall judge necessary for the benefit of the plants, being careful, for the general part, after the great steam has subsided, to shut down the lights always before sun-set; or, if the weather changes very sharp, foggy, or cold driving wet, let them be shut down an hour or two sooner: thus continue your attention in respect to the admission of air, observing, with this care, the lights are to be continued constantly over the plants until almost Midsummer, not omitting, as the warm weather advances, to tilt them high enough in proportion; and as the heat of each day encreases, from morning to noon, tilt them gradually higher in proportion to the power of the sun.

Covering the glasses on nights with garden-mats, &c. must be constantly practised every evening about sun-set, or a little sooner in very cold cloudy weather, uncovering again in the morning about sun-rising, or a little before or after, according to the temperature or heat of the bed, or as the weather is more or less favourable; and in fine, warm, sunny mornings, always uncover as soon as the sun shines freely on the frames, for it is very beneficial to the growth and prosperity of the plants, to enjoy as much day-light as possible. As to the mode of covering, use only a single mat thick at first, augmenting it to two or three occasionally, and never suffer the mats to hang down much over the sides of the frame, which would draw up a great steam, and stifle the plants too much, as observed of the nursery-bed: by these rules the covering must be continued every night until June.

The state of heat of the bed should daily be examined the first week or fortnight after the plants are ridged out, lest it should encrease again so violent as to endanger burning the earth at the bottom of the hills, as well as the roots of the plants; by examining the bottom of the hills, the burning, if any, is generally discoverable, by its having a whitish mouldy appearance; this must be taken away with great care, before it encreases upward to reach the roots of the plants, and, if possible, without disturbing them in growth, immediately adding in its stead a due quantity of fresh earth, keeping the bottom of the hillocks in as narrow a compass as possible, till the danger of burning is past, which will be in a
few

few days; but if the heat still threatens danger to the plants by its violence, make wide holes in the sides of the bed, by thrusting large stakes into the dung in different parts, at which holes the burning heat will evaporate in steam, without ascending to the top, closing the holes again in two or three days with dung.

The moulding or earthing the bed between the hillocks should be began as soon as the heat becomes moderate; therefore, in a week, fortnight, or three weeks, as you shall judge the danger from burning is over, lay in some fresh earth, to be added gradually around each hill of plants, for their fibres will now advance considerably, and striking into the fresh mould, it will greatly encourage them; but observing this precaution, that the earth for this purpose should be previously laid a day or two, towards the sides and ends of the bed within the frame, to acquire a due warmth before it is applied round the hills, which otherwise would chill the fibres; and let it be understood, that this mould is not to be laid all on at once, but at different times, till the whole is earthed to the height of the tops of the hills; so that the whole bed will be now eight or ten inches depth in earth.

With regard to preserving the due temperature of heat in the bed, let it be observed, that, as soon as the first great heat and steam subsides, it will be of utility to lay some dry long litter, or straw, waste hay, or dry fern, around the bed and frame, especially in early work; it will defend it from the inclemencies of weather, by preventing violent or driving rains, snow, or sharp cold, penetrating winds, or severe frost, from insinuating into the interior part of the bed; and by which precautions the heat will be continued in fine order till it begins naturally to decrease, when a substantial lining of hot dung must be added to one or two sides of the bed, as ordered for the nursery bed, and as hereafter directed in its proper place.

In respect to watering, a moderate sprinkling will be necessary about once a week or ten days, though, in sunny warm weather, it is probable twice in that time will be requisite, or oftener, as the warm weather advances; chusing, in winter and spring, always a warm sunny day, any time from ten to two o'clock for this operation; but, as the warm season advances, be more early in the day, and increase the quantity of water, being careful, in cold weather, to have the chill taken off,

as hath been already directed of the nursery-bed; observing, that early in the year it is not proper to water too freely all over the plants and young fruit, especially when there is but little sun; but rather give the water mostly between the vine, out of the spout of a small watering-pot, placing a piece of tyle, or oyster-shell, to water on, to prevent the mould from being washed from the fibres, so removing it to different parts of the bed; but, in fine weather, water should also be given now and then moderately all over the leaves of the plants, which will prove a considerable refreshment to them. At each time of watering, in either method, always shut down the lights for half an hour, or an hour, particularly in the winter and spring waterings. When you at any time water all over the plants, observe, if the sun should then, or soon after, shine out with much force, give a slight shade of a mat over the glasses an hour or two, lest, by its power through the lights, it scorch the leaves where the drops of water adhere to their surfaces; but when the season is so considerably advanced, that the sun is powerful, the general waterings should be performed in a morning before nine, or in an afternoon about three or four o'clock, when the heat of the day is past.

Having, when the plants were in the nursery-bed, directed their first pruning, called stopping, observing, if that operation was then omitted, it must now be done the first opportunity, according to the former directions.

The plants being thus stopped, they, in ten days or a fortnight, will each send forth two or three lateral shoots or runners, observing, that when these have advanced two or three joints in length, if they do not shew fruit, a second pruning should take place, by stopping each such runner at the third joint; this will promote their putting forth each about three fruitful runners, i. e. such that will probably shew fruit at almost every joint; for it is from the lateral or side runners, acquired by the first or second stopping, we are principally to expect the fruit, as you will see by observation, though, in good kinds, it frequently happens that the runners produced, in consequence of the first stopping, shew fruit at the first or second joint, which is a particular advantage in early crops. According as the runners advance, conduct them along in regular directions, at equal distances from each other, fixing them in their proper position, by gently pegging

pegging them down to the earth with small hooked pegs, which you will repeat occasionally during their advancing growth, and they will soon spread all over the bed.

In three or four weeks after ridging out, the plants may be expected to show fruit, though sometimes that is effected in a week or less, and perhaps at the first or second joint, when the plants are not more than five or six weeks old; and I have had fruit shew at the first joint, a day or two after ridging out, in the beginning of February, as big as a small barley-corn, and cut the same fruit for the table before the month was out; for the great article at an early season is, to secure and forward the first-shewn fruit to maturity, which, without a peculiar mode of culture, will turn yellow, and drop off in their infant state.

When the plants therefore shew fruit, particular attention is necessary, for one thing, to the keeping up a moderately brisk and regular heat in the bed, by proper linings, &c. for a great deal depends upon this, that the plants may be continued in a state of free growth, whereby the infant fruit will advance freely, and flower strong; and the next thing particularly to be observed, is, always to perform the office of setting or impregnating the young fruit, according as they come into full blossom, by injecting the farina of the male flowers, as hereafter directed, for the male flowers most commonly accompany the female or fruit blossoms; so that by practising this, and if a good heat is preserved in the beds, with the due admission of fresh air and moderate waterings, the fruit will set and swell freely, so as to acquire a due size for the table, probably in a week or ten days, or a fortnight at most, after performing the impregnation; and that, if you began about Christmas, or soon after, the first fruit, with due management, will be ready early in March, and from the same bed a regular succession may be obtained till Midsummer, or longer.

In respect to lining the bed; this may probably be requisite in three weeks or a month, or little more or less, after it is made, but this is according to the substance of the bed; examine, therefore, carefully, when the heat begins considerably to abate, and, on discovery thereof, lose no time, but prepare to line the back-part as soon as possible, for the success of early work depends on keeping up a constant regular heat; having therefore hot dung in due readiness, by previously working it in a heap, as formerly directed; then removing

the litter from the back of the bed, work up the dung lining a foot and half wide, and as high as the dung of the bed, or rather half a foot higher, to allow for settling, for the lining ought to be substantial, otherwise it will not have the desired effect; observing, if the heat of the bed is considerably declined, you may also line the front, otherwise it will be better to defer it a week longer; and, in ten or twelve days after that, you may shake up the first lining, adding thereto a little fresh dung, which will greatly revive its heat, observing also the same of the front lining; and by thus alternately making, and renewing the lining, you may preserve a fine growing heat in the bed till June, when, by the nature of the season, the plants will succeed without farther aid of artificial heat, though it is necessary to allow them the shelter of the frames and glasses until the middle or end of that month.

At each time of lining, do not omit laying two or three inches of earth at top, to restrain the rank steam of the dung, which would rise and enter the frame at the smallest hole or crevice, or at the opening of the lights designed for the admission of air.

Observe, likewise, that as a fresh lining always causes a very copious steam, and sometimes a strong heat, due attention must be given to tilt the glasses in proportion.

And when you renew the lining for the last time in the end of April, or in May, lay six or eight inches depth of earth on the top, at the same time raising the frame at bottom, that the earth of the lining and bed may join, so as the fibres may shoot into the new earth; it will greatly encourage the roots, add fresh vigour to the plants, and will sufficiently recompence you for the trouble.

Where there is more than one range of framing, if the whole space between was filled up at the above time with hot dung, it would be an additional advantage to the crop.

With regard to the work of impregnation, or setting the fruit above-mentioned, it is a most necessary operation of art incumbent on the gardener in the early culture of these plants, to be done according as the flowers, both male and female, come into full bloom, and is performed by injecting the farina of the male into the stigmata of the female blossom, which is as necessary to the generation of plants, as the seed of animals is to their respective species. In hermaphrodite plants the male and female organs are included.

cluded all within the same flower, and consequently the impregnation is readily effected by nature; but all the species of *Cucumis* being monoecious plants, male and female flowers distinct, both, however, on the same plant, the male blossoms being furnished with the stamina, having their antheræ loaded with a golden powder or farina, designed by nature to impregnate the females, so that the conveyance of this male powder to the female flower, either by nature or by art, is absolutely necessary, as, without its aid, the young fruit will constantly turn yellow, and drop soon after they have flowered: in summer, when the plants are fully exposed, the gentle breezes of wind, as also the bees roving from flower to flower, having the farina adhering to their legs, and some other accidents, are supposed to convey a sufficient portion of the farina for fecundating the females; but in winter and early spring, when no wind nor bees, &c. have free access into the frames, shews the necessity of performing the impregnation by art to these plants in particular, by carrying the male to the female blossoms; and the following is the method.

On the day the flowers of both sexes fully open, or the day after at farthest, is the proper period for performing the operation; the male blossoms are with facility distinguished from the females by the rules already observed; therefore, at the period of growth just mentioned, gather some of the best male blossoms, and apply their antheræ to the stigma of the females; some direct whelming them down over the female flower, so striking them with the fore finger, to cause them to discharge the farina; but the most certain method is, that having gathered the male blossom with the shank or stalk thereto, pull off the petal or corolla carefully from about the stamina and antheræ; then taking the shank of the flower betwixt your finger and thumb, apply the antheræ, or top of the stamina, to the centre of the three stigmas of the female blossom, and whirl it about two or three times, that it may discharge or inject a due portion of the *pollen* or farina, into the said stigmata or female organs, and then cast it away, using a fresh male blossom for each impregnation, unless the males are scarce, as sometimes is the case early in the year, when one male with care may be made to impregnate two or three females, as it also sometimes happens at an early season, that a fruit blossom opens, and no males forward enough on the plants; in this mortifying circumstance you must have

recourse to your neighbours, some of whose plants may probably be on the contrary extreme. Some, in performing the impregnation, insinuate the male organs in betwixt the stigmata of the females, and so leave it till it naturally drops out; and sometimes they twist the top of the female corolla together to keep the other part in; but all this is unnecessary: practise, as before directed, and cast the male part away as soon as you have performed the operation, which, if well executed, and there is a good heat in the bed, the young fruit will make amazing progress in a few days, advancing with the flower at its extremity; and when from about three to five or six inches in length, is fit to cut for the table.

Always make it a rule, during the early season, to set every promising fruit, according as they come into blossom; and the critical moment is, the middle of the first day the blossom opens, or the second, at most; being careful never to water too freely over the newly-set fruit, especially at an early season.

Some, to encrease the growth of the newly-set fruit, stop the runner, on which it is situated, at the first or second joint above; it may be practised to some of the earliest; but too frequent stopping occasions a great number of weak shoots, and a confusion of vine.

The importance of the above operation is so essential in the early culture of Cucumbers, that it should never be omitted, as by the practice you may always make sure of the first, and every fruit that shews, whereas, without this care, if the culture of the plants is ever so well conducted, no fruit will set till late, as by many is experienced, except by chance some straggling bee may have crept into the frame; so by the fertilizing dust sticking to their legs, accidentally perform the operation. The doctrine, however, of impregnation, is by some disputed, in respect to its necessity and efficacy; and what is surprising, the Rev. Mr. Hanbury, in his *Body of Gardening*, gives hints of its inutility, as unnecessary and of no effect, advancing, that good crops of early fruit may be expected without its assistance; but this only shews their total want of practical experience in this very important process, as well as in that of early Cucumber framing; for almost every eminent gardener has proved its great use, and was retained as a grand and useful secret, that many young gardeners, to know it, have given a considerable gratuity.

There

There are, however, no other plant of our gardens that requires the gardener's assistance in the above work of generation, besides Cucumbers and Melons, and these only in their early culture, under frames, or in hot-houses, where the free air, and other means, by which the fecundating function might be naturally performed, is not obtained.

The male blossoms, so essentially necessary in the above culture, are by the ignorant termed false blossoms, and are often pulled off; but this should never be done at any time of year, either in hot-beds, or in the full ground, except, indeed, where they grow in great clusters, in which case they may be thinned off, leaving sufficient for setting the fruit; and, likewise, as the blossom in general fades, it should always be cleared away, especially in early frame culture.

As these plants generally extend their vine considerably all over the surface of the bed, quite to the sides of the frame, frequently sending forth runners from all their joints as they advance, insomuch as sometimes to occasion a great confusion of vine; in which case, if numbers of weak, long-jointed, fruitless shoots, are produced, it is proper to thin them out occasionally, cutting them off close; and where the runners in general are considerably crowded, thin out also the weakest, most irregular, and the fruitless stragglers, so training the main vine, and principal bearing side-runners, in a moderately thin and regular manner; for when the bed is greatly crowded with vine, it, by excluding the necessary influence of the benefit of the sun and air, occasions numbers of the young fruit to drop off in their minority; observing, however, that the regulation of the plants, as above, should, if possible, be begun before the vines are much entangled with each other: clear off also all worn-out or decayed runners; likewise all decayed leaves, and thin the large clusters of male blossom, and pick them off in general when they begin to decay.

When the season is advanced, that the sun shines with great vehemence through the glasses, it is proper to give occasional shade of single mats, an hour or two, in the middle of such scorching sunny days; otherwise, the violence of the sun through the glasses might scorch the leaves of the plants.

As the summer advances, and the days grow long, the sun powerful, and the air mild, afford your plants a large portion of air, by tilting the lights a hand's breath or

more high, in the heat of the day, which should be done occasionally in front, in very hot calm days in May and June; and in very scorching weather, the occasional shade of a single mat, or a little loose hay strewed over the glasses, during the fierce sun, from eleven to two o'clock, is necessary, lest the violent heat through the glasses scorch the leaves and fibres of the roots; at this time do not let them want water, once, twice, or three or four times a week, according to the heat of the weather: observe, likewise, at this time, if the leaves of the plants are grown so large and high as to press against the lights, it is adviseable to raise the frame at bottom about three or four inches, by placing a brick, &c. under each corner, making good all irregularities of the earth of the bed occasioned by this work, filling up also, at the same time, with earth, between the mould of the bed, and that at top of the lining, for the fibres to strike into, as formerly hinted; and if the leaves of the plants are very large and crowded, let some be cut out, so as to admit the air freely: likewise, when the summer is advanced to the middle of June, if the weather is warm and settled, the frame may be raised so high at bottom, as to admit of the end of the plants being trained from under, upon the top of the lining, being careful to cover them on nights with mats the first week after training them out, till hardened to the open air; and towards the end of that month, or beginning of July, may gradually expose the whole to the full air to take their chance for the remainder of the summer, though, if you would continue them in bearing as long as possible, it is proper to continue to defend them on nights, and all excessive wet weather, with the lights.

Thus far is principally the whole culture of Cucumbers in frames, according to real practice, from the sowing of the seed till the maturity of the fruit for eating; and, as the early culture is to many the most difficult task in gardening, and often attended with bad success, by not being generally understood, nor has been sufficiently explained by former authors, we have enlarged the more on this head.

But before we quit this article of the frame-culture, we would just add, as a necessary hint, that, in your proceedings in early work, never depend entirely upon your first sowing and planting, but continue sowing a little seed occasionally, both in the seed and nursery hot-

hot-bed, and in the fruiting bed, after ridging out, either in pots, or in the earth of the beds; so pricking some in pots, as directed before, and plunge them in the earth towards the back of the frame; and by having them of two or three different degrees of growth, they will be ready, in case the first plants should not thrive, or that they are cut off by any accident, as steaming, burning, cold, &c. and some will also be ready for succession crops in new hot-beds, for it is necessary to have at least two different crops in frames, one succeeding the other; and, in either case, it is always good culture to keep up a sufficient stock, if more than wanted the better, as you will have the pleasure of assisting a neighbour with a hole or two, for which there is always great request in the spring season.

The raising or planting Cucumbers in frames may be practised, occasionally, any time from Christmas, as before observed, until the middle of May; though after the middle of April the plants will succeed in hot-beds, under hand or bell-glasses, which is the common culture for the later summer crops, that come in to bearing in June and July, and for which crops you may save the expence of frames, except, however, you have spare frames and lights, when they will, even for these crops, be preferable to the hand-glasses.

The necessary quantity of framing to work for the supply of a family is; for the early crop, if for a small family, a two, or a three-light frame, may be sufficient for the fruiting-bed; but for a large family, three such frames, at least, will be requisite for the first crop, and full as many for the succeeding one.

Early Cucumbers for market is a valuable article, especially in London, as those in March will often fetch thirty shillings a dozen from the retailers, who frequently sell them again at double that price; and, in April, from ten to fifteen shillings is the common price per dozen; after which time they become plenty, and the price falls proportionably every week till August, when the natural ground crop comes in, and when a dozen sometimes will scarce fetch a penny.

Their Culture under Hand or Bell-Glasses.

When intended to raise Cucumbers in hot-beds, under hand or bell-glasses, the seed should be sown about the middle or latter end of March, and the plants will be ready

to ridge out about the middle or latter end of April, or first or second week in May, which periods are as soon as these plants will succeed under these kinds of glasses, and in which they will arrive at full bearing in June and July.

The long green prickly is the most eligible Cucumber for this crop; some of the green and white Turkey kinds may also be sown for variety, as also any of the other sorts; but let the first mentioned be preferred for the main crop.

The merit of hand or bell-glasses in the culture of Cucumbers is, that, for a general summer crop, it saves the expence of frames and lights, as a crop of Cucumbers, to come in for use part of May, all June and July, may be obtained by planting, at the above-mentioned time, in hot-beds, under these glasses, without the aid of frames; so that persons not accommodated with frames and lights, or do not chuse the expence, or that they are all employed in the early Cucumber or Melon beds, which cannot possibly succeed without their protection, may, for the summer crop, as above hinted, have recourse to the hand or bell-glasses, at the proper period, April and May, which is of much importance to those who raise large quantities, and particularly to the market-gardeners, some of which, in the Neat-house gardens near Chelsea, in the neighbourhood of London, work 2000 holes in a season, each hole covered with a hand or bell-glass; therefore these glasses, at the afore-mentioned time, being placed on moderate hot-beds, you may either sow seed under them, or put in plants, but the latter is greatly preferable, having them previously raised in a nursery hot-bed, hereafter directed, till in the rough leaf two or three inches broad, that, being ridged out, four plants under each glass, in the middle or latter end of April, or in May, they will fill the glasses with their vine, by the time the weather is warm enough, in the beginning of June, to admit of their being trained out from under them, for the vine must have scope to run, as they will not succeed if too much cramped within the compass of a hand or bell-glass; for which reason, it will not admit beginning to ridge out earlier than the middle of April, lest the plants grow too large for the glasses, before the weather is warm enough to train them out; however, in default of other conveniences, you may sow some seed in the end of March,

or beginning of April, under hand-glasses, not however, where they are finally to remain, especially if before the middle of the last-named month, but rather, if possible, in a sort of nursery hot-bed, made for one or more of these glasses, to raise the plants to the size before mentioned for ridging out at the proper time; but in default of plenty of hot dung, or plants, &c. may sow the seed at once in a final hot-bed, under these glasses, eight or ten seeds in each, any time from about the middle of April to the middle or latter end of May, thinning the plants to four in each hole; and even by this practice of raising them, they will be only two or three weeks later, and will have fruit a month sooner than such that are raised from seed sown in the natural ground the beginning of June, which rarely arrives to a bearing state before August.

But the most eligible method for raising plants for the hand or bell-glass crop is, in March aforesaid, or very early in April, either to sow the seed in the Cucumber or Melon hot-beds already at work under frames, or where there is no room, or there are no frames at work, make, about the middle, or toward the latter end of March, a hot-bed for a frame of one, two, or more lights, according to the quantity of plants required, observing nearly the same rules in making the bed and sowing the seed, as directed in the frame culture: likewise prick the plants, when in the seed-leaf, either in pots, or at two or three inches distance in the earth of the bed; but, for the greater convenience of ridging-out the plants with balls of earth about their roots, it is more advisable to prick most of them in pots, four in each, as observed of raising them for the frames; observe also nearly the same rules for giving air, covering up on nights, giving occasional waterings, keeping up the heat of the bed, and stopping the plants at the first joint, as there directed; and in about three, four, or five weeks, when the plants have rough leaves two or three inches or more broad, and beginning to shoot runners, they are of due size for ridging-out.

The most proper time for ridging out under these glasses is, from about the middle of April to the middle or latter end of May.

The hot-beds for this ridging out are to be of hot dung, prepared as exhibited in the framing; observing, that as the season for this work is April and May, the beds need not be quite so substantial as is necessary at a more early season, allowing, however, if in

April, dung enough, if possible, to make the bed three feet six wide, and two feet and half high; though, if not made till May, two feet height in dung may be sufficient, and, at either time, the length of course proportionable to the number of hand-glasses you design to work, allowing them to stand at three feet six inches distance, in one row along the top of each bed.

The ridges or beds are, according to the season, to be made either entirely on level ground, or in a trench fifteen or eighteen inches deep; observing, if you would ridge out in April, that, as the beds will require lining in three weeks, to revive the heat, to carry on the plants till the arrival of warm settled weather in June, it is therefore proper to make them entirely above-ground, to admit of lining the whole of each side quite to the bottom; but if you do not ridge out till May, no linings will be required; and as the ground will then be warm, dry, and free from standing water, it is proper to make the bed in a trench three feet wide, and near half that in depth; so that the bed being above half way in the ground, and the upper part to be covered on the sides and top with the earth of the trench, the whole will assume the appearance of a ridge of earth, and, by being thus moulded, and all cased over with earth, it will preserve the heat the longer.

On consideration, however, of ridging-out in April, conclude to make the ridge entirely on level ground; therefore stake it out three feet and half wide, and as long as convenient; then wheel in the dung, and work it up regularly straight and upright on each side to about two feet and half high; but if four feet wide, and the above height, it will support a more durable heat, and be of additional advantage, for the bed will settle a foot, and there are often many cold nights between this time and the end of May; observing, if more than one range is to be made, make them one before another, allowing a space of three or four feet between, which may afterwards be occasionally filled up with linings of hot dung and earth, which will prove very beneficial to the plants, finishing each bed, by shovelling up all the short dung at last, and lay it at top.

Having thus made the ridge or ridges, they, in three or four days, will have settled, and the heat arisen, then level any inequalities at top, making that part even and smooth, and proceed to mark out the distances for the plants,

plants, and mould the places for their reception; for, as there are no frames to confine the heat and steam, you may always venture to ridge out within the week; the bed being levelled at top, mark out exactly along the middle thereof the places for the glasses and plants at three feet six inches distance; and, if the bed is very substantial, that, previous to moulding it, you may, if convenient, as a precaution, the more certainly to preserve the earth from burning, plaister cow-dung an inch and half thick on the places where the plants are to stand, as hinted in the frame culture: having, however, marked the distances for the plants, lay on each of these places about a bushel of rich earth in a hillock twelve inches high, and broad enough for a hand-glass; at the same time cover the other parts of the bed, between, and on every side the hillocks, two or three inches thick, with the same sort of compost, and directly place a hand glass over each hill, shutting them down close to draw the heat up soon, and cover them on nights with mats, and, when the earth is warm, put in the plants.

The next day, or day after, the earth will be sufficiently warm for the reception of the plants; therefore, having previously watered the plants the day before, that the mould may cling in a ball about their roots; then removing the plants with a ball, and levelling the tops of the hillocks broad enough for each glass to stand, plant one pot of four plants in each hillock, as before directed for the frames, giving directly a little water, and put on the glasses, and, if they flag at the approach of sun, afford them a moderate shade the first two or three days; but if they are carefully transplanted, with balls to their roots, they will not want much shading, and the less the better.

Being now ridged out, care must be taken to admit fresh air to the plants in the warmest time of every mild day, by tilting one side of the glasses, from about half an inch, to one, two, or more high, according to the heat of the bed and warmth of the weather; but shut down the glasses in due time towards evening, or sooner, if the weather changes cold, keeping them close on nights, and all very cold bad weather; and cover every night, all over the glasses and ridge, with mats, until June; also occasionally in all hard rains.

Give also occasional moderate waterings, according to the rules exhibited in the frame culture.

In a week after ridging-out, when the great heat of the bed will be abated, then begin to

earth it by degrees all over, to the height of the hillocks, which will encourage and preserve a due heat about the fibres of the plants; and if previously a wreath of large straw-bands, made of any kind of long litter, is placed round the edge of the bed, just on the top of the dung, fixing them thereto six or eight inches high, with long sharp-pointed sticks thrust into the bed, it will support the sides of the earth, so as to admit of moulding the bed to its full width, and will preserve that part of the mould from being dried too fast by the sun and winds.

Towards the middle of May, or sooner, if the heat of the ridges abate, and the nights continue cold, a lining of hot dung to both sides of the bed will be of very great advantage; make this fifteen or eighteen inches wide, beating it firm on every part, raising it three inches higher than the dung of the bed, to allow for settling, and immediately earth it at top with rich earth to the thickness of that on the ridge; this lining will be most serviceable in a triple degree; the fresh dung will revive the heat of the bed, the earth at top affords additional scope for the fibres to strike into, and the bed, being augmented in width, gives an opportunity of training the vines regularly to their full extent.

As the days encrease in heat, and the plants in growth, admit air accordingly, by tilting the warm side of the glasses in proportion, to harden the ends of the runners gradually, to be trained out from under the glasses, when the weather is become warm and settled.

In the latter end of May, or beginning of June, the plants will have filled the glasses with their runners; they must then be trained out, by elevating the glasses on props: this, however, must not be done too hastily before the first or second week in June, if possible, to retain the plants till that time under the glasses, for we have often very cold nights till the end of May, and sometimes a week longer; therefore, in the first or second week in June, according to the settled temperature of the weather, and advanced growth of the plants, prepare to raise the glasses on every side three or four inches high, on bricks, pieces of wood, or notched sticks, and lead the runners out regularly at equal distances; fasten them down with hooked pegs, to secure them against the power of winds, observing to continue the covering of mats every night, and all very rainy or bad weather, for the first fortnight after they are thus trained out from under the glasses; continue the glasses.

glasses also over them till July, or, if continued all summer, it will preserve the head or main stem of the plants from injury of weather.

When the runners advance from under the glasses, if some dry reeds, clean wheaten straw, or small brushy or branchy sticks, are spread on the surface of a few holes, for the vines to run upon, it will preserve them clean, and the earth from drying too fast; and the fruit will be better preserved from spotting, which often is the case in wet summers, when they lie on the ground.

In hot dry weather, when the vines are advanced considerably, and in fruit, do not omit supplying them with water two or three times a week; though in July, when in full fruit, they, in very dry scorching weather, will need water every day, or even twice in a day, in the morning before eight, and in the evening after four o'clock, giving, at this time, a watering-pot full, at least, of water, to each hole, watering equally all over the bed to the very outside; and by thus preserving a due moisture in the earth, during the great heat of the season, the plants will shew fruit abundantly, and it will set and swell surprisingly fast to maturity.

As to the operation of setting or impregnating the fruit, as directed for the frames; this, if you are anxious about having some of this crop fit to cut as soon as possible, may be performed to those that first shew whilst under the glasses; but after the vine is trained out into the full air, there will be no great necessity for taking that trouble, for reasons already mentioned.

This crop will continue in bearing from about the end of May, or beginning of June, until the latter end of August, or till September.

But with respect to ridging-out these plants in May, as we formerly observed; the ridge, or hot-bed, at this time need not be more than three feet wide, and about two feet deep in dung, nor will it require lining; and therefore I should advise to make it mostly within the ground, in a deep trench, the earth of which will mould the bed; mark out, therefore, a trench, where the ground is perfectly rich and light, three feet wide, and in length at pleasure; dig out the earth twelve or fifteen inches deep, or, in dry ground, a foot and half, if the goodness of the soil will admit, laying the earth in a range close along each side, to be ready wherewith

to mould the ridge; and if more than one ridge is intended, make them parallel, and allow a space of four or five feet between.

The trench being ready, then wheel in the dung, and spread it regularly to the full width and depth of the trench, raising it, however, if in the beginning of the month, near two feet thick; but if about the middle, or after, eighteen inches depth in dung may be sufficient; observing, in either case, to work it as firm as possible with the fork, and directly mould it all over the top nine inches thick, and mark out the places for the glasses, by placing sticks exactly along the middle, at three feet and half distance, and then trim the rest of the earth of the trench equally up to each side of the bed, close to the earth at top, so as to cover every part of the dung, and form the whole into a broad bed five feet wide, assuming the appearance of a raised bed of common earth, trimming the edges straight by line; this done, put on the glasses, and, at night, cover the whole with mats, to draw up the heat, and next day, or day after, the earth will be warm; then put in the plants, as before directed, give water, and set on the glasses, covering them, and the bed in general, on nights, with mats; likewise, in excessive rains, night or day, at first planting, otherwise it might chill the bed, being of moderate substance, so as to occasion a total decline of its heat. As to their other culture, it differs not from those ridged out in April, only the bed is not designed to be lined; but in all other respects the same management is to be observed.

Along the edges of the bed may be planted rows of coss-lettuce, which will come off time enough for the plants to run.

Another method of ridging-out in this month (May) is, that, in cases of scarcity of hot dung, instead of forming one continued ridge of dung, in a trench, as above directed, it may be worked in holes, one hole for each glass; dig therefore holes two feet wide, and twelve or fifteen inches deep, and three feet and half from centre to centre; observing, if you design more than one range, allow six feet between each row of holes; then let a large barrow full, as much as a man can wheel, of good hot dung, be worked firmly into each hole; earth them directly nine inches deep, place on the glasses, and when the earth is warm, either put in seed, or rather plants, managing them as before directed; afterwards, at your convenience, dig and work up;

up the earth on each side the rows, so as to form every range of holes into a sort of bed, five or six feet wide, for the vines to run upon; and along the edges of which you may plant rows of coss-lettuce, as before observed.

By this method many of the London gardeners ridge out their main hand-glass crop, particularly those of the Neat-houses near Chelsea, where the ground is so rich, light, and warm, many of whom work several hundred glasses.

Their method is; the ground is generally planted with early cauliflowers the October before, under the hand glasses, in rows eight feet apart; in the space between is sowed radishes and spinach about Christmas, or a little before or after, for spring crops; these come off early in May; then they make the holes there for the Cucumber, and the glasses being then ready at hand, and unemployed for that season with the cauliflower, they are placed over the Cucumbers; the cauliflowers coming off in July, they, in each place, plant a trench of celery, or sometimes rows of endive or lettuce; and the Cucumbers having done their best by the third or fourth week in August, and those of the natural ground in perfection to succeed them, they are pulled up, and the ground dug, and directly sown with winter spinach; and in September or October, the celery, endive, or lettuce, planted where the early cauliflowers grew, being all cleared off for market, the ground is dug, and either planted with cauliflowers again, or with several rows of cabbage-coleworts, at a foot distance in the rows, which will be fit for market by Christmas; but these gardeners generally change the ground every year or two in different crops.

In ridging-out Cucumbers in holes, as above, if you place a few holes near a south wall, paling, or reed-hedge, you may, in June, train the vines of the plants up against those fences, both for the sake of variety, and to improve the size, beauty, quality, and flavour of the fruit; for they are generally larger, more fair and free from spots, more solid, firm, less seedy and watery, than those which lie on the ground.

By this practice you may particularly improve the long green, and white Turkey kinds, &c.

Or, if you place some branchy sticks, as for peas, about three or four feet high, the plants being of the cirrhose climbing kind, they, with a little conducting at first, will

assist themselves in ascending upon the sticks, by means of their *cirrh*i, or tendrils, though, when designed to train these plants off the ground, they succeed best when trained against some kind of fences, either of close, or of open work, and free to the full sun.

Raising them under Paper Frames.

In default of hand or bell-glasses, a few holes of Cucumbers, for private use, may be brought to bearing in June, under shelters of oiled paper, either pasted on ridged or arched frames, made of lath, or other open work, four feet wide, ten long, and three high; or on small open frames the size of hand glasses; or by pasting three or four sheets of strong paper together in a piece, each such piece to cover one hole of plants, previously oiling it, as is directed for PAPER FRAMES; so in the beginning, or towards the middle of May, ridging out some plants, or, for want thereof, seed, on hot-beds, as before directed; then place on your frames directly, or, if you use only the sheets pasted together, as in the latter method, first arch over each hole of plants with two or three pieces of hoops, &c. placed across one another, eight or ten inches high, and place the paper over each arch or hole of plants, laying bricks, boards, or some other substance, to prevent them from being disturbed by boisterous winds; but either of the other two methods would be better than this: however, let either of these shelters remain over the plants day and night, till the middle or latter end of June, admitting fresh air occasionally, covering every night during the cold weather with mats; also all times when it rains excessive hard the first three or four weeks after planting.

Under these temporary shelters, by aid of a moderate heat of dung, you may obtain Cucumbers a month or six weeks sooner than any can be raised from seed entirely in the natural ground.

Raising them in Hot-houses.

Cucumbers are often obtained in hot-houses any time in winter, and early in spring, with less trouble sometimes than in hot-beds under frames, not, however, always with success of such plentiful crops; but as pineapple stoves are now common in most parts of the kingdom, it is worth trial, and if but a few very early fruit is obtained, it will compensate for the trouble.

The seeds may here be sown any time from
October

October till March; though to have them as early as possible, it is proper to sow in October; and for the greater certainty of success, repeat it in November and December, and even every fortnight during winter; but let it be observed, that those sown about Christmas, or soon after, will be considerably the most prosperous and successful crops: let the seeds be sown half an inch deep in small pots of rich earth, that have been previously plunged in the bark-bed a day or two, to warm the mould, retaining the pots therein, and the plants will rise in a few days, which, when two or three days old, prick in pots, as in the frame and hand-glass culture, plunging them also in the bark-bed, giving now and then very moderate waterings; and as to air, they can have it only in common with the other plants of this department; observing, as the plants advance in growth, to stop them at the first joint, as hath been already directed; and when they are just ready to shoot runners, let them be transplanted with the entire ball of mould about their roots, into large pots or boxes, to remain to fruit, but rather into trough-fashioned boxes, about three feet long, a foot wide at top, nine inches at bottom, and ten inches deep, having them filled with the best rich light earth, and placed in the stove a day or two before; then plant two pots of plants in each trough, and give a little water: as to the proper situation in the stove for these boxes, &c. to remain, they may be tried in different parts; where there is room you may plunge one or more half way in the bark bed; others may be placed on top of the flues, elevating them upon bricks, or some other materials, so as there may be a vacancy of ten or twelve inches between the top of the flue and bottom of the boxes, both that the heat of the flues may have due vent, and that it may not dry the earth in the boxes too fast, and the boxes being so elevated, the plants will be nearer the top glasses, which is of much importance to these plants for receiving the greater benefit of the sun; and for which reason, if some boxes, or one long trough was erected near the top glasses, it would be of considerable advantage, which might readily be done by iron or wooden brackets, suspended from the cross-bars at top, and the proper place is along under the uppermost or back part of the top glasses, just over, or rather a little behind the back walk of the stove, that it may not shade the other plants, or

water drop therefrom upon them, and that they may be nearer the warmth of the flues, fixing them at about twelve or fifteen inches from the glasses; in which situation, in this department, I have always observed Cucumber plants, at an early season, to be more prosperous and fruitful than when more distant from the top lights; observing, however, that during the residence of the Cucumbers there, at an early season, the uppermost tier of the top glasses must not be drawn down, but admit air occasionally at the lowest tier, or front lights.

When the plants are thus finally planted out in either of the above methods, your care is requisite to supply them duly with moderate waterings twice a week, or oftener, if it shall seem necessary.

Likewise, when the vines or runners of the plants advance, fix up some neat laths for them to run upon, and to which they must be fastened occasionally as they advance in length.

When they shew fruit, practice the operation of setting them, as directed in the frame culture.

In this, the hot-house culture of these plants, different methods may be practised by way of experiment; as that of sowing the seed and pricking the plants in pots, and afterwards transplanting them with balls where they are to remain to fruit, as already directed; or only just raise the plants, as above, till two or three days old, and transplant them into the fruiting boxes; or sow the seed at once in the said boxes, and suffer the plants to remain to fruit; or some plants might be plunged in the tan between the pines, and their vines suffered to run among them.

Try also plants previously raised in pots in dung hot-beds, under frames, till in the second or third rough leaf; then transplant them with balls into the boxes in the stove.

Cucumber plants, raised in a common dung hot-bed in September or October, till in the second or third joint, and then transplanted with balls into the stove, will sometimes afford a few fruit in November and December.

Cuttings of Cucumbers, taken off five or six inches long from some healthful plants of the summer crops towards the end of September or beginning of October, planted in pots of rich light earth, and plunged in the bark-bed, will take root, and often break forth into runners, and produce fruit in November and December.

Cucumber.

Cucumber plants may be raised in the stoves to a proper size to plant out in hot-beds under frames, where they are to fruit for the early crop, which will save the trouble of making a dung hot bed for sowing the seed and nursing the plants: sow the seed about Christmas in pots, and prick the plants into others, as before directed, and when in the first joint, and begin to shoot runners, transplant them with balls into the fruiting frames.

Raising them in the natural Ground for Picklers, &c.

In the last week in May, and first and second in June, is the time to sow Cucumbers in the natural ground, for picklers, &c. before which time neither the seed nor plants will succeed in the natural earth, nor open air.

This crop succeeds the hand-glass Cucumbers, and comes into full bearing the beginning of August, and continues bearing plentifully until the middle of September, either for picklers, for eating, or for culinary purposes; but it is from this crop that the general supply for pickling is commonly gathered.

Observe, that although we mention the last week in May, or beginning of June, for sowing, it is, however, not every year that the weather is favourable enough to admit of performing this sowing in May; for it must not be done before the weather is become warm, dry, and settled, as, if you put in the seed while cold or very wet weather prevails, or when the ground is cold and wet, it will surely rot; or, if any plants come up, they will acquire a stunted dwindling growth, and come to nothing; and of late years it is commonly the first or second week in June before the season is temperate enough for sowing this crop: you must not, therefore, be too eager in sowing before that time, unless the season proves very fine and warm; but, at any rate, never put in a seed before the 24th of May, and then it ought to be only in a warm dry situation, unless, indeed, you have any spare hand-glasses, which you may place over the holes; but for some years past, the first and second week in June has, for the general part, proved the most successful season for sowing in the open natural ground.

The sowing is to be performed at once in the place where the plants are to remain to fruit.

Chuse, therefore, for this crop, a spot of

your richest ground, in any of the common quarters, open to the full sun, either a clear spot, or, where there is none, may be sown between crops standing distant in rows, and are soon to come off the ground; as, between rows of cauliflowers, early cabbages, between wide rows of early beans, or in the alleys between onion-beds, particularly those for culling, or in the alleys between beds of transplanted lettuces, or such like temporary crops, that come off by the time the Cucumbers begin to advance considerably; however, where there is ground vacant from crops, in a proper situation, it should be preferred, as the whole can be properly digged, and divided into proper beds.

The order and manner of sowing is, if a clear piece of ground, let the whole be neatly dug, and then divide it into beds five feet wide, having a foot-wide alley between bed and bed; then along the middle of each bed mark out the holes or places for the seed at three feet six inches distance; let the earth in each place or mark be finely broken, and then hollow it with the hand in a basin-like form, about fifteen inches diameter, and two or three deep; then, in the middle of each hole, drawing a little earth to one side, sow ten or twelve seeds half an inch apart, and cover them over half an inch deep with the earth.

But when you are necessitated to sow between other crops, as above hinted, you must be content, for the present, only to dig holes in each patch where the seed is to be sowed, observing the distance in the row as before, and allow, if possible, six feet between each range of holes, sowing the seed, as already directed, and when the crop comes off, the ground between the rows may be digged, and formed into beds, as before advised.

The crops sowed in the above methods, is according to the common practice of the most eminent kitchen gardeners, and designed principally for the vines or runners of the plants to be trained along the surface of the ground.

But as these plants are of the tribe of *cirrhose* climbers, nature having furnished them with *cirrh*i, or tendrils, seems to indicate that it never intended them to trail on the ground; therefore some may be raised in such order, as for their vines to climb upon sticks, &c. in the manner of peas; when this is intended, I should advise to sow them in drills, running north and south, five feet distance, first forming with a hoe or spade a sort of shallow flat trenches

trenches a foot wide, and one or two inches deep, the distance as above, and along the middle of each of these shallow trenches draw a small drill a finger's breadth deep, in which sow the seed, and cover it about half an inch with the mould; here, when the plants begin to run, place to each row some branchy spreading sticks a yard high, whereon to conduct their runners, and on which they will also naturally assist themselves in ascending by means of their tendrils, and will produce plenty of fruit, which, by being elevated from the earth, will be fair, firm, and free from spots.

Or, if some are sown on a sunny border close along under a wall, paling, reed-hedge, or any other fence, and to which train the plants, and here they will produce handsome fruit, clear, and free from spots, less watery and seedy than those that lie on the ground, and much better flavoured, and consequently preferable both for eating and pickling.

The above methods of sowing, for training the plants upon sticks, or against fences, is principally recommended for practice to a few in private gardens for family use, which would by no means be practicable in large grounds, where great quantities are raised for market.

The seed being, however, sowed in either of the above methods, I advise, if very dry and hot sunny weather, to sprinkle the holes every day or two with water; but let this be done very moderately, only just to preserve the earth in a middling degree moist; for, if the earth is rendered very wet, either by watering or excessive rains, the seeds are very apt to rot: preserve, therefore, only a very moderate moistness, and, if the weather is hot and dry, the seed will sprout in a few days; but if the season is very dry, and the sun scorching, the shade of a cabbage leaf to each hole, to prevent the earth from drying too suddenly, will prove very beneficial to the free germination of the seed, and the plants will rise in six or eight days; at which time you will do well to watch the sparrows, for these birds often devour the seedlings at a great rate, just as they issue from the ground.

But in sowing this crop in warm dry seasons, it is the practice of many of the London gardeners, that if the weather proves excessive hot and dry, so as to parch the earth considerably, they, previous to sowing, chit or spear the seed, by soaking it in water; that is, they put the seed in soft water, and place it within a hot-bed frame, about twenty-

four or thirty hours, or long enough for it to spear, i. e. germinate or sprout half a quarter of an inch long, which they call spearing the seed; they then sow it directly, giving water freely in dry weather, and the plants will often rise in two or three days.

Another method of treating this crop is, that in cold wet seasons, as it sometimes happens, even in June, I would advise, where practicable, to raise the plants on a slender hot-bed in patches; and when about a week or ten days old, just beginning to shew the rough leaf, transplant each patch of plants with a ball of earth into the natural ground, in the places where they are to fruit, a patch to each hole; this is an eligible practice in bad seasons, and practised by many of the London gardeners, who sometimes raise plants enough to furnish an acre or two of ground, and by that means have much better crops, and come sooner to fruit by a fortnight than when raised in the common way in a cold wet season, as above. The method is as follows.

In the last week in May, or first in June, make a hot-bed three or four feet wide, and fifteen or eighteen inches high, the length in proportion to the quantity of plants required; earth it directly about three inches deep, and sow the seed: the method of sowing is, to dot in the seed in clusters in small holes an inch and half apart, and half a one deep; that is, with the two first fingers and thumb, contracted at top, dot holes in the earth of the bed the above distance and depth; as you proceed, drop eight or ten seeds in each hole, and when the whole bed is thus sown, immediately cover in all the holes evenly with fine earth: or, instead of dotting in the seed, as above, may draw small drills south and north the bed, near an inch deep, and two asunder; sow the seeds in the drills in clusters, as before, and earth them over the same depth; but I would rather recommend dotting them in: then, in either method of sowing, let the bed be directly arched over with hoops or rods, in order for covering on nights, and all bad weather, with mats; if the weather, after sowing, should prove hot and dry, give moderate sprinklings of water, and the plants will be up in three or four days; and the seed being thus sown in clusters, the plants will rise also in bunches, which, when they shew the rough leaf, are then fit to transplant; previously water them some hours before, that the earth may cling to their roots;

then proceed to take them up with the point of a hollow or scooped trowel, each cluster or patch separate, and with a small ball, which will readily adhere about the fibres, placing the bunches of plants carefully in a flat basket, to be carried to the place of their destination, which should be previously digged and formed into holes, basin-fashion, as in the common method; break the earth fine, and plant one bunch of plants in each hole; close the earth well about them, and give a little water, but they will not require shading; for being removed young, and with balls, they will not feel their removal; so repeat the watering occasionally, and the more sun they now have the better, and they will grow surprisingly; observing, when they are fairly in the first rough leaf, they must be thinned to four of the best plants in each hole, as directed in the general culture following.

As to the general culture of this crop of Cucumbers, raised in either of the above methods, the principal articles to be observed are; that, if dry weather, after they are come up, let them be moderately watered every day or two, at least; and when they have been up a fortnight, or when their first rough leaf is advancing, it is proper to thin them to four or five plants in each hole, reserving the strongest plants at equal distances, and mould up their shanks, pressing it gently but closely about them, so as to spread the plants different ways, and give some water, to settle the earth where loosened by thinning out the superabundant plants: if there are deficiencies in any of the holes, make them up with the best of the plants thinned out. After this, continue your care of watering in dry weather; it will be necessary three or four times a week, and sometimes every day, and even twice a day, morning and evening, in July and August, when the weather is excessive hot and dry.

In the beginning of July, when the plants begin to run, let the holes be lightly hoed with a small hoe, to destroy weeds, and loosen the earth; drawing a little mould about the shanks of the plants, press it gently between with the back of the hand, to separate the plants as much as possible from each other, at equal distances, and in the direction you intend they shall run; let the whole surface be also lightly hoed, and if gently loosened two or three inches deep, as far as the plants will extend; it will greatly encourage them.

As the vines advance in length, it will be of much advantage to peg those down which you design to run upon the ground, to prevent their being disturbed by wind; and if some reeds or small sticks are spread for the vine to run upon, which might be readily effected to a few holes in private gardens, the plants will fasten themselves thereto by their clasps, and by keeping the fruit from the ground, preserves them from spotting.

Those which are intended to be trained to sticks or fences, should have that work begun when they are advanced near a foot long, and continue conducting the runners thereto occasionally as they advance in length.

Be sure, in dry weather, after the plants are considerably advanced, to water freely, as before hinted; and in July and August, when they come into fruit, and the weather hot and dry, to water every day.

These crops come into bearing the end of July, or beginning of August, and continue fruiting in great plenty till the middle or latter end of September; but after the middle of that month the fruit is often spotty, very humid or watery; therefore, when the fruit is required for pickling, begin gathering for that purpose in August, and continue it a month or six weeks, or as long as the fruit continue fine and unspotted.

For this purpose of pickling you should look over the plants three times a week, to gather all the fruit that are fit; when they are from about two to three inches long, and not thicker than your finger, they are of proper size for pickling; observing, if possible, to gather them when they are dry and clean, each with its stalk, and the sooner they are put into the pickle after gathering, the greener they will be, and more firm and crisp to eat, which are commendable properties in pickled Cucumbers.

The fruit for pickling sell in the London markets from five to ten shillings per thousand, though, in fine, favourable, and forward seasons, I have known them sold for half a crown or three shillings; it is amazing to see what prodigious quantities are brought to these markets in a morning; one gardener perhaps brings fifty or a hundred thousand at a time for his own share; they sell them most commonly wholesale to the oil-men, who pickle them to retail out in small quantities to chandlers-shops and families.

The necessary quantity of plants to produce picklers for family use, is from about ten to fifty

fifty or sixty holes, according to the demand of the family; every ten holes will afford near a thousand picklers in the course of the season, i. e. from about the beginning of August until the middle of September.

Much wet weather is very unfavourable to this crop of Cucumbers; it chills the earth and fibres of the plants, which being naturally tender, they in such seasons neither produce fair fruit, nor a plentiful crop, nor is it of free growth, and the plants continue but a short time in bearing before all the fruit of each gathering will be spotty, and very unfightly to the eye, watery, and ill-tasted.

But in dry warm summers, let them be duly supplied with water, and they will bear abundantly, and the fruit will be fair, arrive fast to perfection, and continue fine till the autumn rains, or long dewy nights, towards the middle of September, chills the earth and plants, when the produce will begin to be both scanty, deformed, and spotted.

Of having them late in Autumn and in Winter.

But if Cucumbers are required in perfection for the table as late in autumn as possible, it is proper to place some frames over a few holes of the best plants in August, and let them be shielded with the lights every night, and all cold wet weather; and thus, by preserving the plants from cold and excessive moisture, they will retain a healthful and moderately free growth till October or beginning of November, producing tolerably handsome fruit.

If the plants are growing on a dung-bed, formerly a hot-bed, I should also advise, towards the middle or end of September, to line it on each side with hot dung, to throw in a little heat, which would be of much advantage; but even if the plants are growing in the full ground, it might be done by digging a trench at the back and front two feet wide, cutting it a little under, so filling it with hot dung, treading it in firmly, and as it settles continue adding more.

Or, to have late Cucumbers, some might be sown in the natural ground, in a warm situation, the middle of July; place a frame over, and shelter them all along occasionally with the lights; they will come into bearing the end of August, and, with due shelter, will continue longer than those sown a month or two before.

Or, if some seeds are sown in the natural ground the end of July, or beginning of Au-

gust, and transplanted with balls into a slender hot-bed under frames, about the latter end of the last-named month, they will come into bearing towards the latter end of September; and with proper shelter, and occasionally lining the bed three or four weeks after making, they may be continued in bearing a few all October, and greatest part of November.

And, if some seed is sown in a slender hot-bed, or under glasses, the latter end of August, and transplanted into another of moderate structure in the middle of September, they will arrive to a bearing state in October, and, with care, will probably continue producing a few till December.

If some seed is sown in September, as above, and transplanted into a hot-bed of tolerable substance, under frames and glasses, in October, managing them nearly as the early plants, you may stand a chance of having them produce now and then a fruit till Christmas; and in this bed may also be sown some seed in October and November, &c. to try to extend a crop of plants still farther; there is, however, no great expectations to be formed from either of these crops, the declining season of the year being unfavourable to their growth; and is, therefore, only worth practising in some family gardens, by way of curiosity, where a fruit or two at an uncommon season may be greatly valued.

But by thus continuing to sow some seed occasionally, from early in spring till late in autumn, many have cut Cucumbers every month in the year.

It is, however, to be considered of all these autumn-raised crops of Cucumbers, that, by the nature of the season, they, if ever so well managed, can never succeed so well as the spring and summer crops; but as a few fruit in October and November, after the general season is past, may be easily obtained by the afore-mentioned rules, it will be esteemed a rarity, and in most families highly acceptable.

Saving the Seed.

To save Cucumber-seed, some fruit either of the frame or hand-glass crops should be left for that purpose; for those of the late crops, in the natural ground, seldom ripen their seed perfectly.

Therefore, about May, or June, or July at latest, mark two or three of the finest fruit in each hole, and these situated near the main stem, that there may be the greater chance

chance of having the plants from that seed shew fruit near home, as the gardeners term it, meaning their beginning to shew fruit at the first, second, or third joint, which is a principal merit in these plants, particularly the early crops.

But to insure still a greater chance of having early fruiting plants, I advise you to leave one or two of the earliest frame fruit, which appear at the above-mentioned joints of the plant, and this will be choice seed for your early framing, as the plants will seldom fail shewing fruit at the beginning of their first runners.

Having, however, marked the fruit for seed in either of the above crops, they must be permitted to remain upon the plants till June, July, or August, according to the forward or late growth of the fruit; observing, those which are produced and left for seed in March, April, or May, will be ripe in June and July; but those produced in May or June will not be ripe till the middle of August, for the seeds ought to be perfectly well ripened.

When they are fully ripe, cut them from the plants, and set them up on end against a sunny wall or hedge two or three weeks, or till their outer coat begins to decay; then cut them open, and turn out the seeds and pulp together into a tub or other vessel, to remain a week or two, stirring it up every day, that the pulp may rot and separate from the seeds; and then add some water, stirring the whole well about with a stick, the pulp will rise like scum to the top, and the seeds will settle to the bottom of the tub; so that by a repetition of two or three waters the pulp will be separated entirely from the seed, which should then be spread upon a mat in the open air a few days, until perfectly dry, when it should be put up in bags or boxes, and preserved in a dry room for sowing.

This seed will support its growing quality eight or ten years, but is in the greatest perfection in the third and fourth years, at which age they produce more fruitful plants than younger seed, which is apt to fly vigorously into vine, and shew fruit sparingly.

Second Head.

CUCUMIS MELO, the Melon, or Musk-Melon, (*Melo*).

The Melon, as we before observed, is, according to the Linnæan system, a species of *Cucumis*, and considerably the most valu-

able species of that genus, in respect to the excellence of its fruit, which, for deliciousness of flavour and taste, is next in estimation to the pine-apple, the flesh or pulp being both pleasant and grateful to the stomach, and its smell and taste indicate it of an aromatic quality.

Class, order, and characters, the same as the *Cucumis*.

Of the Melon, there is but one real species of the plant, but of the fruit there are innumerable varieties, with respect to figure, size, colour of the rind, and flesh or pulp.

The species is,

CUCUMIS *Melo*.

The Melon.] *Cucumis* with roots composed of numerous, very small, widely spreading fibres; long trailing stalks, divided into many branches, spreading on the ground, furnished with tendrils; roundish, angular, rough leaves; smallish, bell-shaped, yellow male and female flowers, the females succeeded by a large, oval, and sometimes roundish fruit, often channelled, or ribbed longitudinally, having a firm musk-scented flesh, and many oblong seeds included in a watery pulp.

This fruit, in different varieties, is of various sizes, from about four to ten or twelve inches in length and diameter, in most sorts ripening externally to a yellowish colour, and some ripen green, and others white, but have mostly a reddish flesh or pulp, except one variety, which is green both in rind and pulp, as hereafter described.

The varieties of most estimation at present in the English gardens are,

Common Musk-Melon—A large, oblong-oval, longitudinally-ribbed, and netted-wrought Melon, having a reddish tolerably rich flavoured flesh; and the plants being of the hardier kind, generally set a plentiful crop of fruit.—This is also one of the best sorts of Melon for mangoes, and for which purpose the London gardeners cultivate principally this variety for the supply of markets.

Romana Melon—A roundish, moderate-sized, ribbed, and netted Melon, somewhat compressed at both ends, and with a reddish firm flesh of a fine rich flavour, the plants good bearers, each often setting from about five or six to eight or ten fruit, and is one of the best sorts, both for an early and general crop.

Cantaleupe, or Armenian Warted Melon—A large, roundish, deeply-ribbed Melon, a little compressed at both ends, and the surface full.

full of warted protuberances, and with a reddish firm flesh of a most delicious rich flavour, of which there are some varieties—Large Black Carbuncled or Black-rock Cantaleupe Melon, being of a blackish green colour, having the surface covered with high, rugged, saxtile protuberances—Large White Carbuncled Cantaleupe Melon—Orange Cantaleupe Melon.—These varieties are the finest of the Melon kind, with respect to the richness of flavour of the fruit, and which by the Melon-eaters are preferred to all the other sorts; but the plants being rather more tender, do not set fruit so freely, nor in such plenty, they often not having more than from one to two or three fruit on a plant, and that in a three-light frame sometimes not more than five or six fruit, and frequently not so many; as the fruit, however, obtains the highest estimation, the several varieties of this sort are now generally valued for the principal crop in family gardens; observing, that, to preserve these varieties distinct, they should not be cultivated in the same frame with other sorts, nor with each other, for the commixture of farina would occasion a degeneracy; also by saving the seed long in the same garden, the fruit often gradually loses its saxtile or rock disposition, and the surface becomes quite plane, bearing great resemblance to the Romana Melon.

This variety derives the term Cantaleupe Melon, from Cantaleupe near Rome, the place where it was first cultivated in Europe, brought thence from Armenia.

Small Portugal Melon—A smallish round Melon, having a reddish flesh of a fine musky flavour, and the plants are plentiful bearers, each often setting from eight or ten to twenty fruit, which, however, is more by half than should be left to come to perfection.

Green-fleshed Melon—An oval, moderate-sized Melon, having an even, smooth, green rind, and the flesh or pulp ripening to a greenish colour, which is highly flavoured.

Large Green-rinded Melon—A large roundish-oval, green, smooth-rinded Melon, having a reddish flesh.

Black Galloway Melon—A roundish oval, middle-sized, slightly-ribbed, dark-green, smooth Melon, having a reddish, rich-flavoured flesh, and the plants excellent bearers, but the sort not at present very plentiful in England.

It was brought from Portugal many years since by a lord Galloway.

Netted or Wrought Melon—An oval, middle-

sized, scarcely ribbed Melon, having the surface closely wrought with raised net-work, and hath a reddish flesh.

White Spanish Melon—An oval, smallish, white, smooth-rinded Melon, having a reddish pulp.

Zatta Melon—A very small, roundish, warty-rinded Melon.

Observe, that although all the above kinds be only varieties of the same species, yet, by care in cultivating them separate, they may be continued all tolerably permanent.

There are many other intermediate varieties of less note, but a few of known good qualities is better than many different sorts, some of which probably not much better than gourds; and of the varieties here specified, the *Romana* and *Cantaleupe* kinds are considerably the most worthy of attention, as these two sorts ripen to a much higher degree of perfection; but the other varieties also ripen perfectly here, and often of a rich and good flavour, though at all times inferior to the two above-mentioned sorts, more particularly the true Cantaleupe kind; however, where there are great quantities wanted, and all proper conveniencies, I should advise, for the sake of variety, to cultivate some of each sort; but to give preference to the *Romana* and *Cantaleupe* for general crops.

The Melon plant is an herbaceous annual, and one of the most singular and wonderful of that tribe, if we consider its slender and prostrate growth, trailing upon the surface of the earth, and being but of six or eight months duration, yet produces fruit of such admirable figure, size, and richness of taste.

It is an exotic from the hot parts of the world, supposed principally of Persia, from which country, however, it was first introduced into the different parts of Europe; and consequently its culture in every part of Britain can be effected only by artificial heat, and constant shelter of glass, &c. till July, as at an early season they require a temperature of heat almost equal to that of our pine-apple stoves.

The principal season of ripe Melons in England, is June, July, and August; they, however, by different sowings and plantings, may be obtained from May till October; but they are always in the greatest perfection in the times before mentioned.

The flowers of the Melon are consequently *monoecious*, like the Cucumber, as being of the same genus and class, male and female apart on the same plant, the males standing immediately

immediately on the summit of its foot-stalk, without any appearance of germen or fruit under it, and the females discover the round germen or embrio fruit under its base, when not bigger than a pea; observing, that the male blossoms are by nature designed for fertilizing the female flower, as observed of the Cucumber, so must not be pulled off until a full crop of fruit is set.

Observations on their General Culture.

With regard to the propagation of the Melon, the plants being annual, are raised every year from seed, sowed at different times in spring, in hot-beds of dung or tanner's bark, under frames and glasses, &c. they requiring continual aid of artificial heat and shelter, from the time of sowing until June or July, for they will at no time succeed in the natural ground, at least rarely perfect fruit; and each crop requires two different hot-beds, that is, to be sowed in one, and the plants nursed therein till a month or six weeks old, that they begin to shoot runners, then transplanted into a second and final hot-bed, to remain to fruit.

The season for sowing is any time from the beginning of January until the middle of April, according to the conveniencies there may be for their culture, and time the fruit is required in perfection; for the early crops to be raised in January, February, and beginning of March, require very substantial hot-beds, under constant shelter of garden-frames and lights, until July; but the later crops, sown in the middle of March and in April, succeed with more moderate hot-beds, and may be ridged out in April and May under hand or bell glasses, or oiled paper frames, and the plants will set and ripen their fruit under these shelters; observing, that the early sowings in January sometimes produce ripe fruit in May, but come into full bearing in June; and those raised in February, and early in March, ripen fruit in June, July, and August; and sowings performed any time from about the middle of March till that of April, furnish ripe fruit principally in August and September, and sometimes in October.

Observe, therefore, that, like the Cucumbers, crops of Melons may be raised in three different ways; under frames and lights, under hand or bell glasses, and under oiled paper; each of which shall be exhibited under a separate head.

The materials principally necessary in their culture are,

Frames and glass lights for early, and hand-glasses, &c. and oiled paper lights, for late crops; and for each crop good mats for covering on nights; all as observed for the Cucumbers.

Horse stable dung, a plentiful supply both for making the hot-beds, and for occasional linings, which must be in quality, quantity, and preparation, as hinted for Cucumbers, and in the article HOT-BEDS.

But sometimes in the Melon culture bark hot-beds are employed, or of bark and dung together, which, where tanner's-bark can be easily procured, on account of its regular and durable heat, is a very proper material for hot-beds in the culture of Melons, either used alone, or mixed with hot dung, as explained in its proper place.

As to mould, the Melon, like the Cucumber, will prosper in any rich pliable kitchen-garden earth, prepared some months in a heap; but the favourite and most prosperous soil for the Melon is a fine mellow loam, taken from the surface of a pasture field or common, enriching it with about one-third of rotten neat's dung, or thoroughly rotten dung of old hot-beds, preparing the whole in a heap, and managed as directed under the article COMPOSTS; observing, that when it is to be used, not to sift or screen any, only break it well to pieces with the spade.

The situation, or place for making the hot-beds, should be dry, warm, full the to sun, and sheltered, as for Cucumbers; likewise observe, not to dig any trench for the early hot-beds, but make them entirely on the surface of the ground, for the reasons there assigned.

It is generally advised to cultivate Melons as far as possible distant from Cucumbers, lest, by an intercommunication of their *sarina*, it should cause a degeneracy; there is apparently some reason in this: however, when we consider that the two plants are real different species, I believe there is no great danger to be apprehended, as in the case of varieties.

The seed, and its kind, being material articles, you should be particularly careful to procure such only which have been saved from the very finest fruit of the respective approved varieties; this, if possible, should be two or three years old, for the reasons observed of the Cucumber seed; but when you are obliged to use new seeds, it is proper either to hang them in a paper, or phial, in a dry room

room near the fire, all winter, or in a phial, exposed in a dry window to the sun; or may carry them in your pockets three or four weeks, either of which expedients will dry up much of the watery parts, whereby the plants will be less luxuriant and more fruitful. We receive Melon seeds annually from France, Spain, Italy, and other hot countries; but I would caution against depending on these for a principal crop, for not being inured to this climate, the plants from such would be more tender and delicate in their culture, less fruitful, and the fruit often of much less value, than those of seeds saved at home; therefore, only a plant or two of these foreign seeds should be raised at first, just to prove the quality of the fruit.

From the time of sowing the seed to the maturity of the fruit, it is commonly near four months, and sometimes longer; for the plants seldom shew fruit till they have shot several runners, which, from the first appearance of the plants, will be at least six or eight weeks in effecting; from the appearance of the fruit till it is fairly set, a week or fortnight; and from its setting till fully ripe will be about forty days.

The proper quantity of hot-bed in the culture of Melons for private use is, that for the smallest family there cannot be less than one three-light frame for the early, and three hand or bell glasses, or three holes under oiled paper, for the late or succession crops, allowing two plants to each light of the frame, the same to each hand-glass, or hole under the paper lights; and supposing each plant, one with another, to produce about three fruit, so that in a three light frame, and in three holes under hand glasses, or oiled paper shelters, there will be but about from thirty to forty Melons; though of the smaller sorts of Melon there will sometimes be from six to ten, or twelve, or more, on a plant; but six or eight is as many as the plants are able to bring to perfection: however, for the supply of a middling family, two three light frames, and, at least, six hand or bell-glasses, &c. will be necessary to furnish a tolerable supply during the season; and for a large family, four three-light frames, at least, or twelve lights, will be requisite, and double that number of hand-glasses, or holes of plants under paper frames.

We now proceed to the different methods of culture; and first of their early culture in frames, observe as follows.

Their Early Culture in Frames by Dung Hot-beds.

The time of year to begin the culture of Melons in frames, is January, February, and beginning of March; but when designed to have Melons as early as possible, we commonly begin in January, though the beginning of February is a more successful time of sowing to have a good crop; if, however, you begin early in January, it is proper to sow also twice in February and March for succession crops; likewise to be ready in case of accidents to the early plants, or that they should not thrive, as is often the case at a very early season.

The seed may be sowed, and the plants raised, either in a hot-bed of early Cucumbers now at work, in the same manner in every respect as for them directed; or, where none is, make a hot-bed for a one-light frame on purpose, observing exactly the same rules with respect to dimensions, making, framing, and earthing the bed, sowing the seed, and other management, as directed for the early Cucumbers; likewise, when the plants have been come up three days, that their cotyledons are a little expanded, transplant or prick them into small pots for the convenience of removal, as there directed; but of these, i. e. Melons, put only two plants in each pot, plunging them in the bed, and manage them as above till fit to ridge out; for the Cucumbers and Melons, being nearly of equal temperature, the same degree of heat, air, &c. suits both in this part of their culture; it would therefore be superfluous to trouble the reader with a repetition, since the particulars are fully exhibited under the article of *The Early Culture of Cucumbers in Frames*.

In this nursery-bed they are to be continued a month or six weeks, till their first runners begin to advance; observing, as their shanks rise in height, to earth them up by degrees with fine mould, till the pots are full, for this will greatly encourage them, and they will come fast into the rough leaf, and begin to form joints and shoot runners.

Observe, when their two or three first rough leaves are fully expanded, and another forming in the centre, appearing like a bud, which part being also the end of an advancing shoot, it should just at this period of its growth be stopped, i. e. cut or pinched off close to the second or third leaf, as advised for the Cucumbers, to procure lateral shoots, called runners; for it is from these, or others issuing from them, that we are to expect the fruit;

fruit ; and when these first runners appear, the plants are ready for ridging out into the fruiting hot-bed.

The plants from the time of sowing, till arrived at the above size for ridging-out, take about five or six weeks growth.

The ridging-out, or fruiting hot-bed, should be prepared in due time to receive the plants when arrived to the proper age and size above mentioned ; observing, to prepare fresh hot dung a week or two in a heap, as for the Cucumbers, sufficient for one or more three-light frames ; let the bed be made entirely on the surface, for the opportunity of lining, carrying it up three feet and half, or four feet high, raising the back or north side three or four inches higher ; directly put on the frame and lights, to defend the bed from chilling rains, and to draw up the heat, tilting the glasses behind for the steam to pass away ; and in a week, or ten or fifteen days, according to the substance of the bed, its first great heat will abate ; then prepare to mould it, and put in the plants, observing the necessary precautions, as for the Cucumber beds.

The bed being ready, as above, then wheel in your prepared mould, and lay just under the middle of each light about a bushel of it in a heap, for the immediate reception of the plants, forming each heap into a sort of conical hillock about fifteen inches high ; and by thus having the hills of earth this height, is proper both that the plants may be near the glasses, which is of importance in early work, and to allow them a good depth of earth ; for they should generally have a greater depth of mould than Cucumbers, the plants being more impatient of moisture by watering, which is also prejudicial to the prosperity and flavour of the fruit, that, therefore, by allowing a good depth of earth, they will shift much longer without the aid of water : when the hillocks are thus formed, directly earth the other parts of the bed within the frame three inches thick, just to keep down the steam rising immediately from the dung ; then shut down the lights, and when the earth is warm put in the plants.

In a day or two the heat of the dung will have sufficiently warmed the hills of earth ; then bring the plants in their pots ; being two in each, plant one pot of plants, with the balls of earth about their roots, in the middle of each hill, as directed for the Cucumbers ; and if the mould should appear dry, give a little water towards the outside, being careful

not to wet the plants much at this time ; and as soon as planted shut down the lights, to draw up the heat about the roots of the plants, but tilt them again in due time, to pass off the steam.

The plants being now ridged out into the fruiting hot-bed, observe, that as the glasses are to be continued constantly on the frames till July, your daily care is to admit fresh air at all opportunities in calm weather, by tilting the lights behind from about half an inch to two, three, or four high, according to the temperature of the heat and steam of the bed, and that of the outward air, which must be also observed occasionally on nights at first ridging-out, if there is a great steam, for this must not be pent up, nor stagnated for want of air ; cover the glasses also every night with mats, one or two thick, as shall seem necessary, but never let them hang down all over the sides of the frame and bed, as often done, which would draw up a violent steam, and exclude the air too much from the plants, and draw them up weak and of a yellow colour ; give water also occasionally when the earth appears dry : observing, that in the performance of all of the above works in this bed, to follow strictly the same rules as exhibited in the ridging-out bed of early Cucumbers ; but to keep in mind, that Melons being rather impatient of moisture, must have it more seldom, and less in proportion, than for Cucumbers, especially near the main stem and principal roots ; for by much moisture these parts are apt to canker and rot, so should be watered mostly at some distance from these principal parts, and never to wet the vine much at an early season ; but when there is not less than twelve or fifteen inches depth of earth on the beds, they will not need water oftener than once a fortnight ; and sometimes, when the earth is of a loamy nature and depth as above, and pressed down close, that it may the better retain its natural moistness, the plants, after two or three waterings, till they have firmly established their roots, will often succeed without, or, at least, with very little more water ; and in which case they generally set their fruit freely, and it ripens to a rich and high flavour, for redundancy of moisture retards the setting of the fruit ; and although, after it is fairly set, occasional waterings will encrease its magnitude, yet much of it greatly debases its flavour and taste ; but on the other hand observe, that where the earth of the beds is of a light texture,

texture, or of but a moderate depth, the plants will all along require occasional waterings, especially in warm sunny weather; let it however be remembered, that when the plants exhibit their first shew of young fruit, no water, or as little as possible, should be given, until the fruit is set as big as large walnuts, when, agreeable to the nature and proportion of earth, and other rules as above mentioned, and as hereafter hinted, use your discretion accordingly in watering.

Examine with care for the first week after ridging out, that the earth of the hills and roots of the plants do not receive too much heat from the violence of the bed; and if there is danger, remove some of the earth around the lower part of each hill; and if any is burned at bottom, add directly some fresh in its stead, and in a few days or a week the burning quality will subside; then replace the removed mould again about the hillocks.

After danger of burning is past, cherish the heat as much as possible, by laying dry long litter around the sides of the bed, to defend it from chilling wet and cold piercing winds.

When the heat begins to decline considerably, be sure to revive it as soon as possible, by adding a substantial lining of hot dung to the sides of the bed at different times, as practised to the Cucumber beds, using the same precaution of earthing the top, &c. to prevent the steam of the linings entering under the bottom, or at any part of the frame; for the rancid steam coming directly from the dung would destroy the plants.

When the fibres of the plants begin to advance through the hills of earth, let some fresh mould be layed in the frame at different times to warm, and by degrees add each parcel around the hills, till the whole bed is gradually moulded nearly as high as the top of them; but rather let the top of each hill be about an inch higher, that the main stem and principal roots may be preserved moderately dry, otherwise, being watered, would soak to these principal parts, and cause them to rot, as being very impatient of copious moisture from watering, &c. therefore, according as the mould is occasionally added, observe the afore-mentioned precaution; also to press it down close, that by lying compact it may retain a due moisture in itself the longer, so as the plants will require to be but seldom watered.

As the runners of the plants advance, dis-

pose them with regularity, and when they are three joints long, if no young fruit appears, it is proper to perform a second stopping, by taking off the end of the extreme joint, to promote a more speedy supply of other lateral runners, which, together with others, naturally arising from them, will sufficiently spread the bed with vine; and it is from these lateral shoots we may generally expect soon to see plenty of young fruit.

At the first training the vines, as above, if some dry and clean reeds are thinly spread upon the surface of the bed for the vines to run upon, it will preserve all the runners and young fruit from the damp of the earth, as well as prevent the earth and upper fibres of the roots from being dried too fast by the sun; some, for the above purposes, cover the bed all over closely with plane tiles; but this I should think rather excludes the necessary benefit of sun and air, too much from the earth and roots of the plants.

When the young fruit begins to appear, it is of much importance to support a due temperature of heat in the beds, by occasional linings, &c. do not omit this, because the whole success of having the plants set a regular and a plentiful crop of fruit depends on a good bottom heat, both to warm the earth sufficiently about the fibres, as well as the internal air of the frame; for these fruit being so extremely tender whilst young, that without a proper heat they set very sparing and stragglingly, generally assuming a slow, stunted, and irregular habit of growth; maintain, therefore, the necessary degree of heat, and the fruit will set freely, and swell fast in magnitude.

At this period also of the first appearance of the fruit, I should advise to forbear watering, if possible, till the fruit is set as large as good walnuts, as we above observed; observing, that if the plants are growing in a tolerable depth of soil of a loamy nature, they will shift very well without any during that period, or longer, unless the earth should be very dry indeed, and then let them have it but sparingly; for if any considerable portion of water is given when the fruit is setting, the vine will acquire a glut of sap, and continue shooting with great luxuriance, which is contrary to the nature of these young fruit, as, being of such a delicate temperature in their infant state, and even during their minor growth, that the exuberant quantity of sap in the branches causes them to turn yellow, and drop off soon after they have blossomed, and

and sometimes after they have set as large as an egg, and more especially if there is not a due degree of warmth in the beds.

According as the young fruit appears, you will observe it accompanied by abundance of male blossoms; these must not be picked off, as too often practised, their *pulvis antherarum*, or powder of their antheræ, being absolutely necessary for fecundating the female flowers, and fertilizing the young fruit; it is therefore of importance, not only to retain these flowers, but that to assist nature, it is proper, in the early crops, to perform the operation of setting, i. e. of applying their antheræ to the stigmata of the female blossoms, as directed for the Cucumbers, using for this purpose such male flowers whose antheræ are duly ripened, and well furnished with *farina*, which you may readily know by previously applying the antheræ gently to the thumb nail, to which some of the *pollen*, if ripened, will adhere; so using one or two males to each female blossom, and it will be found to assist greatly in setting the early fruit.

Air, at this time of blossoming, will also be particularly beneficial in promoting the free setting of the fruit; do not omit therefore to admit it every mild day, according to the rules formerly mentioned.

After setting the fruit observe, that as they are most commonly produced on the lateral runners, issuing from the sides of the main vine, and that exuberancy of sap retards their setting, I would advise, if your plants are rather luxuriant, that, to restrain the sap from flowing too abundantly into the setting fruit, instead of stopping the end of the runner, as often done, rather turn it carefully curve-ways, so that the end may incline towards the main stem, whereby the sap will be directed from the bearing runners, and its course continued principally into the more luxuriant branches; and the sooner this is done the better, which, after the fruit is set, and a little advanced in growth, must be turned again into their former position. Many persons prune off the ends of the bearing runners a joint or two beyond the fruit, in order that the whole nourishment of that branch should be directed to it, to make it more certainly stand; but this has often the contrary effect, since stopping or shortening a branch promotes its drawing a greater quantity of sap, which, as we above observed, is contrary to setting these fruit; therefore, those branches on which the setting fruit are immediately situated, should

not be stopped until the fruit is fairly set, and full as big as a large walnut.

Neither is it proper to stop many of the runners, which would occasion their throwing out numerous shoots, and cause a great confusion of vine.

As the fruit sets, and has attained nearly the size just mentioned, the branches on which they grow, if they were turned towards the main stem, as above advised, should now be reconducted into their former directions, that the sap may now find a freer passage to nourish the fruit.

Likewise, as the fruit sets, lay a piece of clean dry tile under each, to preserve it the better from the moisture of the earth.

The quantity of fruit to be expected to set and arrive to perfection, is from about two or three, to eight or ten upon each plant; but this is according to the sorts, for the Cantelupe Melon sometimes does not set above two or three on a plant; on the other hand, the Romana will sometimes set and ripen eight or ten, and sometimes many more fruit will set than the plants are capable of nourishing; but, when this is the case, they should be thinned; and even of the smaller kinds leave only about six or eight of the most promising fruit upon each plant, and not more than five or six of the larger kinds, and never leave more than one fruit upon the same runner, and that which is nearest the main vine is generally the most eligible to leave, though it is best to fix upon that of the forwardest and handsomest growth.

After a tolerable crop of fruit is set, and they advanced in magnitude, if the earth of the bed is dry, take the first opportunity of a mild day to give a good watering, especially if the bed is kept to a proper heat, which, according to the nature of the earth, and its depth on the beds, may be afterwards either wholly discontinued, or less or more repeated, as you shall see occasion by the temperature of moistness, or dryness of the earth; observing, in giving water, let it be rather most towards the sides of the bed, so as still to preserve the main stem and principal root always moderately dry.

Continue also admitting air at all opportunities every day when the weather is fine, which is also very beneficial to the free growth of the young swelling fruit.

Still, likewise, continue to support a due temperature of heat in the bed by occasional linings with the usual care, even till

May;

May; for, by maintaining a bottom heat, the fruit will swell freely, continue a regular growth, and be in a little time surprisingly forwarded in magnitude. In applying the last lining in April, or beginning or middle of May, it is proper to earth it at top equal in depth to that of the bed, as observed of the Cucumber, and by raising the frame the fibres of the plants will strike into the mould, and receive very great benefit, as will be evident from the healthful appearance of the plants, and free growth of the fruit; but observing, this part should be defended from great rains with mats, that the extreme fibres may not receive and convey too much moisture to the vines and fruit, otherwise it would be more adviseable to confine the fibres wholly within the frame.

Shading the plants occasionally from the sun may be necessary in very hot days, when the sun is so powerful as to endanger scorching their leaves, &c. observing the same rules as for the early Cucumbers.

As the leaves of the plants grow large, and press against the glasses, continue to raise the frame at bottom three inches; and as, in doing this, the earth next the frame will be disturbed, directly therefore make good all inequalities; and, if the leaves are considerably crowded, it is proper to thin them a little in proportion, so as that the young fruit may receive the necessary benefit of the sun and air.

If, after a due quantity of fruit is fairly set, and advancing in growth, the vine is greatly crowded, it is proper to regulate them, by cutting off close all small runners, proceeding from the principal fruit-branches, and others, and any luxuriant shoots that support neither bearing runners nor fruit, and such other vine as your observation shall judge to be superfluous or unnecessary, cutting them off quite close, which will greatly encourage the free growth, and promote the size of the Melons.

In May and June, as the vines of the plants will be advanced to the sides of the frame, if you have a full crop of fruit fairly set, they may be pruned so as to confine them within due compass; or, if you would have as many fruit as possible to succeed each other, they may be suffered to run out from under the frame upon the top of the lining, to produce some late fruit to succeed those already set within the frame, raising the frame high enough at bottom for that purpose towards the middle of June; observing, when the vines

are thus trained out, to cover them every night, and all very wet weather, with mats; for the glasses must also still be continued on the frames till the weather is become quite settled and warm towards the end of this, or in next month (July), and then only taken off a few hours in the warmest time of the day, and always put on at night and all wet weather.

When the fruit is nearly full grown, no water, or at least very little should be given; for moisture will considerably retard its ripening, as well as rob it of the richness of its flavour. At this period of growth let each fruit be placed upon a brick, or some flat tiles, placed one upon another, to raise it a little above the leaves, to receive the greater benefit of the sun and air, whereby its flavour and relish will be considerably improved, being careful to turn it every three days, that every part may equally enjoy the benefit of the sun's influence; observing also, at this time, to admit a large portion of fresh air every mild day, by tilting the lights several inches behind, or in front, in very hot weather, which will also contribute very much to the rich flavour of the ripening fruit.

From the setting of the fruit to its maturity, it takes commonly about six or seven weeks, and sometimes more.

The maturity of the fruit is known sometimes by its cracking at the base, as if it would start or recede from the stalk; sometimes by its inclining to a yeilow colour; frequently by imparting a fragrant odour; and when the top of the fruit is soft, it is always a sure indication of ripeness; therefore, observing these appearances of maturity, let the fruit be cut at the proper time; for if suffered to remain on the vine a day or two longer, it will loose much of its flavour. Let it be cut in a morning before the sun shines hot to evaporate its rich juices, cutting each fruit with all its stalk, and lay it in a dry but cool airy place till it is wanted for table.

In the latter end of June, and in July, if the weather is dry and warm, the plants may be gradually inured to the full air, by shoving the glasses off a few hours in fine dry days; but let them not have much rain, lest it rot the main stem of the plants, and it would also debase the flavour of the fruit; therefore retain the glasses ready at the back of the frames, to draw on every night, and all very wet and boisterous weather.

Their Culture under Hand or Bell-glasses.

Principal crops of Melons, to succeed the forward crops in frames, are most commonly obtained by ridging out plants in hot-beds, under hand or bell-glasses, in April or May, for they will then, and not before, succeed by this mode of culture; therefore, that for the main crop to come in after Midsummer, you may save the expence of frames, as observed of the Cucumbers; or if the frames are all employed, or that you are not sufficiently provided with such conveniencies, you may always have a good crop of Melons under these kind of glasses, ripening in July, August, and September.

The culture of Melons under these hand or bell-glasses is effected by sowing the seed in March or April, in a nursery hot-bed, under frames and lights, and when the plants are about a month old transplant them into ridges or hot-beds, under the above glasses, to remain for fruiting; but, in default of frames, the plants might even be raised entirely under hand or bell-glasses, placed on a hot-bed, sowing them in April, and transplant them into a fresh hot-bed in May, under the same sort of glasses, or oiled paper lights; they will sometimes come in for a tolerable crop in August and September; however, the most eligible practice is, where possible, to sow and forward the plants in a hot-bed, under frames, pricking the young plants in pots, so continuing them in the frame hot-bed till large enough to ridge out, then transplant them with balls into the fruiting hot-bed.

The most proper period of time for sowing the above crops is, the third and fourth week in March; but, if possible, for the main crops, never be later than the first week in April.

And the time for ridging-out the plants under these glasses, is from about the eighteenth or twentieth of April until about the middle of May.

For, it must be remembered, that the plants for these hand-glass crops must never be raised nor ridged out before the above-mentioned times, otherwise they would advance too forward in growth, and fill the glasses before the nature of the season admitted of their being trained out, unless sheltered by paper frames, as they must not be confined within the small compass of these glasses, longer than the beginning or middle of June, that the weather becomes settled and warm; nor ought the principal

crops to be sowed nor ridged out later than the times above specified, because they would not be forward enough to ripen their fruit in perfection before the approach of cold weather in autumn.

The seed may be sown, and the plants raised large enough for ridging out, either in the hot-beds of forward Melons or Cucumbers now at work under frames, or in a small hot-bed made on purpose for a one-light box, &c. earthed a few inches deep, sowing the seed either in pots half an inch deep, or in the earth of the bed, drilling it in that depth, so managing the same as for the seedling Melons and Cucumbers for the frames; prick the plants also in pots, when a few days old two in each pot, as in the frame crops, giving them nearly the same culture, and having expanded their two first rough leaves, stop them at the first joint, as there directed; and when a month or five weeks old they will begin to shoot runners, and should then be ridged out into the fruiting hot-bed.

Therefore you must forecast to prepare the dung, and make the ridges or hot-beds in proper time, to be ready to receive the plants at the above period of growth.

The dimensions of the fruiting hot-bed should be four feet and half wide, and, if made in April, two feet and half, or a yard high; and even if made early in May, two feet and half depth of dung will be requisite; nor should it be less than two feet high, made in any time of that month; and the length in proportion to the number of glasses you intend working, allowing them at a yard and half distance from centre to centre, in one row along the top of the bed; observing, that if the plants are ready for ridging out in April, or beginning of May, I would make the bed entirely above ground, for the opportunity of lining the sides when the heat declines; or, at this season, if the ground be tolerably dry, so as there will not be much danger of water standing, the bed may be made in a trench, for the advantage of having it retain its heat the longer, making the trench four feet and half wide, and eighteen or twenty inches deep; but observing, that in three weeks after the bed is made, the trench must be widened a foot and half on each side, and to the full depth to admit of a lining of dung that width and depth to each side of the bed; for hot-beds made for these plants at either of the above-mentioned times, either on level ground or in a trench, will receive

receive considerable benefit by having a lining of hot dung added to each side in three or four weeks after making, which will not only throw in a fresh heat, but, by being earthed at top, gives an additional width for the roots and vines of the plants to extend; observe likewise, that if more than one range of hot-beds are intended, make them one before another in a parallel direction, allowing a space of four or five feet between, which, if afterwards entirely filled up as high as the ridge with hot dung and earth will be of great advantage to the plants.

The ridge or ridges being made, then, according to the rules and precautions exhibited in the hand-glass crop of Cucumbers, prepare to earth it with the proper compost for the reception of the plants, first marking out with sticks the places for the glasses, in a row along the top of the bed, at a yard and half distance; and then, on each place where the glasses are to stand, lay about a wheel-barrow full of mould in a hill fifteen inches high at least, and wide enough for a hand-glass, for this depth of earth is as necessary here as in the frame crops, covering the other parts of the bed between the hills only three inches deep at present, that the burning steam and heat may have due vent, yet to prevent it from evaporating too suddenly, but is afterwards to be gradually earthed almost as high as the top of each hillock: as soon as the bed is thus earthed set on the glasses, one upon each hill of earth, covering the whole with mats at night, to draw up the heat the sooner, and in a day or two the earth will be warm enough to receive the plants.

When the earth, therefore, under the glasses is properly warmed by the dung, then, having previously watered the pots of plants the day before, that the earth may adhere in a ball about their roots, proceed to plant one pot of two plants under each glass, removing the plants out of the pots with a ball, in the manner directed in the early Cucumber hot-beds; and levelling the tops of the hillocks broad enough for each glass to stand; make a wide hole in the middle, and plant the ball of plants, giving directly a moderate watering, and put on the glasses, which must remain constantly over the plants, and be covered every night for a month or two, and all bad weather, with mats.

They being now ridged out, observe, if their removal causes them to flag their leaves at the approach of the sun, it is necessary to in-

dulge them with a moderate shade the first three or four days, when sunny, or till they stand the sun fully without flagging.

Fresh air must also be occasionally admitted in the warmest time of every fine day, by tilting the warm side of the glasses an inch, or a little more or less, according to the heat of the bed and temperature of the weather, having particular attention to shut them down close in due time in the afternoon, or as soon as the weather changes cold, keeping them close on nights; also in all unfavourable weather in the day time, unless there is a very great steam, when, during its continuance, the glasses must not be kept too close; and, if the weather is then cold or windy, the place where they are tilted may be defended with a mat; observing, as the warm weather advances, and the plants make progress in growth, a larger portion of fresh air must be admitted, to harden the runners gradually, in order to be trained out from under the glasses in June.

Cover the glasses and the whole surface of the bed every night with large mats, which must be constantly practised until the beginning or middle of June, or longer, if cold weather renders it necessary.

Likewise, in all heavy or cold rains, at any time, night or day, from the time of ridging out to the maturity of the fruit, particular care should be taken to defend the whole ridge, by a good covering of mats, for much wet would ruin the crop.

Waterings in warm weather once a week or fortnight, in moderate quantities, may be necessary, according to the rules mentioned in the frame crops.

In a week or fortnight after ridging out, when the heat of the bed is become moderate, begin to earth the whole gradually almost as high as the top of the hills on which the plants stand, pressing it down from time to time, that it may retain its moisture the longer, so as the plants may not require much water, for the reasons explained in *the Frame Culture*, raising the whole nearly equal with the summits of the hillocks, preserving the middle of each rather highest, to prevent moisture from soaking to the main stem, &c. as formerly cautioned.

Lining the ridges will be necessary in about three weeks after they are made; this ought not to be omitted, especially to those made in April, or early in May; and having for this purpose a quantity of well prepared hot dung, add.

add it to each side of the bed, a foot and half wide at least, and full as high as the dung of the bed, and directly earth it at top to the thickness of that on the ridge; and thus, by the addition of the linings, that besides the advantage of renewing the heat, it widens the bed to about seven feet, and forms a fine scope for the fibres and vines of the plants; observing, if there are two or more ridges ranging parallel, that if the whole space between was afterwards gradually filled up with hot dung and mould, it would prove still more beneficial to the plants.

Having directed stopping the plants at the first joint to procure lateral runners, if these laterals are also stopped at the third joint they will more speedily furnish a farther supply for bearing, as observed of those in the frames.

About the end of May, or beginning of June, the first ridged-out plants will have nearly filled the glasses with their runners, at which time do not omit indulging them with a large portion of free air at all opportunities, by tilting the glasses every mild day two or three inches high, or in proportion to the temperament of the weather, so as to strengthen the runners, and harden them by degrees to the full air, which, in June, when so much advanced in growth that they can be no longer contained within the glasses, must be trained out; the glasses must then be raised three inches on every side, on props, as for the Cucumbers, and the runners trained out with regularity; but if some dry reeds are previously spread upon the surface of the bed, for the vine to run upon, it will preserve them and the young fruit from the damp of the earth; observing, the glasses are to remain constantly over each hole of plants, to protect the main stem and principal roots the better from wet and other inclement weather, but are now to remain day and night supported on the props, as above: continue also the nightly covering of mats for the first fortnight, at least, after the plants are trained from under the glasses, to protect the tender vines till inured to the full air.

Observe, likewise, that as Melons are rather impatient of copious moisture, it is advisable, after being thus trained out, to protect them with great care from excessive rains and cold, at all times, day or night, by proper covering; the most effectual means for this purpose is, to place oiled paper frames over the ridges, as soon as the vines are trained out, as directed in their culture under *Paper-frames*:

however, in default of these conveniencies, I would advise to arch the bed over with hoops or rods, &c. just to the height of the hand-glasses; so having good thick mats or canvas cloths always ready to draw over the arches, in time of heavy or cold rains, and blustering winds, will be found of very considerable advantage, since a few hours violent rain often injure the plants so greatly, that they never after recover, so as to produce handsome fruit, nor bring any tolerable crop to perfection.

But when the beds are covered with paper frames, these remaining constantly on the beds, effectually defend them at all times, and admit a due portion of light, &c. to the plants.

If, however, you use only mats or canvas, to cover occasionally in cold nights and bad weather, let these be always taken wholly off betimes every fine morning, or as soon in the day as the weather is favourable.

In June and July the plants will spread their runners all over the bed, and will shew fruit abundantly, at which period of shewing fruit very little water should be given, especially if there is a proper depth of earth on the beds, still observing the same rules for this, as directed in the *Frame Culture*; but in very hot dry weather, after the first tolerable shew of fruit is fairly set, and begin to advance in magnitude, a moderate watering once a week, or ten or twelve days, whilst the fruit are taking their growth, will encourage them, promote their size, and encrease the substance of their flesh, being careful to apply the water mostly towards the sides of the bed to the extreme fibres, so as to preserve the main stem and principal roots from receiving too much wet, and be sure never once to over-water the beds, which might prove of very bad consequence; but for the greater convenience of watering at this period, a deep drill may be drawn around the outsides of the bed, and the necessary supply of water poured into these drills, whereby the fibres will receive its benefit without wetting the leaves, branches, or fruit; but when the fruit is nearly full grown, give as little water as possible.

With respect to useless and superfluous or unnecessary branches or runners, if there is any, it is eligible culture to clear them off occasionally, to prevent confusion of vine, and for the prosperity of the fruit, executing it according to the rules laid down for those of the frame plants.

Observe also the same of superfluous fruit, leaving

leaving only such a due quantity of the most promising and best-situated in each hole, as the plants can be expected to bring to perfection.

During the growth of the fruit, observe, that if the ridges are not covered with oiled paper, but only with the hand-glasses, &c. and the weather should prove rather unfavourable or wetish, and that many of the fruit are situated on the advanced vine without-side of the glasses, it is adviseable either to move the fruit gently under their own respective glasses; or rather, where there are any spare glasses, bring these and place over the fruit, contriving each glass to cover as many as may be convenient; for it is necessary thus to protect these fruit from injury of weather, supporting each glass two or three inches high on props; and this shelter of the glasses will greatly improve the size and flavour of the fruit: but in unfavourable seasons oiled paper frames are the most effectual, because, being placed all over the ridge, they defend the plants also, as well as the fruit, both from cold and wet; or, in cold wet seasons, if there are any spare garden-frames and lights, these might be placed over the ridges, as soon as they are at liberty in June, July, or August, so to defend the plants and fruit the remainder of the summer, by shoving on the lights in all unfavourable weather, day or night.

When the fruit is increased somewhat considerably in growth, it is proper to turn them every three or four days, that they may swell equally, and each side have an equal benefit of the sun.

Their ripening is determinable by the appearances of maturity, mentioned in the culture of the early crop, observing also the same rules as there advised in cutting them for table.

Raising them under Paper Frames.

Melons are also fruited in great perfection under oiled paper frames, by placing them over those ridges of plants which are ridged out in April and May, for they will not succeed in earlier crops, but for the crops just mentioned, they are considerably the most eligible shelters to place over the ridges in the middle or latter end of May, or beginning of June, after the plants have filled the hand-glasses, these being then previously removed entirely away, and the paper frames placed upon the bed; for these frames being made

of due width and proper length to cover the whole ridge, and the paper being well oiled with linseed-oil, to render it proof against wet, and more pellucid or transparent to admit the rays of light and heat in a proper degree; that they are continued constantly upon the ridges, whereby the plants are at all times protected from all inclement weather, either wet, wind, cold, or heat, as, although the paper admits the rays of light, &c. yet it, at the same time, affords the most agreeable shade from the scorching sun.

These frames are formed either like the roof of a house, or archways, like the till of a waggon, four or five feet wide, ten long, and a yard high, framed of thin slips of wood and lath, or broad hoops, &c. but those made ridge-fashion with two sloping sides, in the manner of the ridge of a house, are rather the most eligible form, because on one side, may be made two pannels, to open with hinges towards each end, and each pannel about two feet wide, being convenient for giving air, and other necessary work: in either of the above forms the frames are constructed in an open manner, having the ribs or spars, a foot or fifteen inches asunder, or at such distances as to admit of pasting the sheets of paper commodiously; but previous to pasting on the paper, draw lines of packthread, &c. across corner ways from rail to rail of the frame, drawing other lines intersecting or crossing the first, these being necessary for supporting the paper the more effectually against the power of wet and wind; then having some strong printing paper, let it be a little damped, that it may not sink in hollows after it is fixed on the frame; therefore, as soon as it is damped, paste it on the frame; two large sheets will generally range from bottom to top, pasting it securely to the rafters and rails, and so as the middle of each sheet rests upon the intersections of the packthread lines; and when the paper and pasting is thoroughly dry, brush the outside all over lightly with boiled linseed-oil, then suffer the frame to stand in a dry shed till the whole is perfectly well dried before it is used. See PAPER FRAMES.

But for want of regular made frames, a quantity of hoops or rods might be placed across the ridges of plants arch-ways, sticking both ends into the earth, about a foot asunder, and two high, so drawing lines of packthread along from hoop to hoop, both to steady the arches, and help to support the paper;

paper; then paste a quantity of strong paper in large pieces about three or four sheets in width, and in length proportionable to that of the ridges they are to cover; then oil them with linseed oil, and, when thoroughly dry, spread them over the hoop-arches, and secure them by lines drawn from end to end; and that for the admission of air, and doing other necessary work, one side of the paper is readily turned up at bottom as far as convenient.

In respect to the mode of using either of these paper shelters, the plants are previously to be raised in hot-beds, under frames and lights, exactly at the time and manner, as directed for the hand-glass crops, and to be ridged out also at the same times and manner there mentioned; observing, that, in default of hand-glasses, these paper frames may be used as soon as the plants are ridged out; but in this case the ridging out should not be performed till May: but the most successful way is, when there are hand-glasses sufficient, to place these glasses over the plants at first ridging out, as directed in the hand-glass culture, managing them in the same way in every respect, till the plants have filled the glasses with their runners; then remove the glasses away, and place over the paper frames.

When these shelters are placed over the plants, free air must be admitted in proportion to the temperature of the season, either by opening the pannels less or more, according to the warmth of each day, or by tilting one side of the frames at bottom, &c. for the article of fresh air must not be omitted at all opportunities, particularly when the plants shew fruit, the air being not only necessary to strengthen the plants, but also to assist in the impregnation of the fruit, for the reasons explained in the early Cucumber work; and towards the end of June, when the season is warm, the frames may be raised at bottom about four inches.

It is also necessary to defend the plants over the above shelters with mats every night till towards the middle of June; likewise, occasionally, in all hard rains, day or night.

These paper shelters never last but one season, that is the paper; but as to the frames, they, with care, will continue useful several years, so must be fresh papered every spring, in proper time to be ready to place over the beds.

Raising them in Bark Hot-beds.

Having before advanced hints respecting the

merit of tanner's bark hot-beds in the culture of Melons, observe, we propose them principally as fruiting beds; that is, previously raising the plants in dung hot-beds, as already directed, and then transplanting into the bark-beds.

With respect to the merit of these sort of hot-beds for this purpose, it must be considered, that as the Melon plants are generally between three and four months from their first appearance till they produce ripe fruit, and they all the time require the constant aid of artificial heat, which, though they are fruited in great perfection in that of dung, i. e. dung hot beds, yet those of tanner's bark being considerably of more durable and regular heat, the plants by that aid may still be fruited to greater advantage, and with less trouble, because, if made entirely of new tan, no lining, or but very little, will be necessary, nor is there such danger to be apprehended from steaming or violent heat, as in dung hot-beds; but it must be remembered, that the purchase of the tan renders these kind of hot-beds more expensive than dung, though, if both these materials are obliged to be purchased, and the tan can be obtained within a moderate distance, there is but an inconsiderable difference in the expence; for you cannot have a good cart-load of hot dung brought home for less than three shillings, and in some places five or six, or more, and you may have sixty bushels of tan, about as much as three horses can draw, for three half crowns.

But, in case of scarcity of new tan for the above purpose, the waste or cast-off bark of the stoves, mixed with a quantity of new, might be used, provided, however, the old tan is not become quite earthy; so mixing one half old to one of new, which will form a moderately strong and durable heat, and will answer for beds made not earlier than the middle of February, or beginning of March.

Or, for the latter crops, beds might be formed entirely of cast-off bark, provided, as above observed, it is not become very earthy, and its fermenting property not quite exhausted; which, if not, when fresh worked up, and formed again into a bed, will renew its heat, though in a moderate degree, therefore should not be used for beds earlier than March and April, and which, if made in a pit formed of post and planking, so as to admit of a substantial lining of hot dung

to each side in six weeks or two months after making, would be an additional advantage to the plants.

Observe, that either the above mentioned bark-beds for the culture of Melons, must be made in some kind of pit, or frame, to confine the bark, which otherwise could not be formed into a bed, either in a bark-pit covered with glass lights, as exhibited in the article BARK-PIT; or, in default of such a pit, one might be formed of post and planking, of width and length for one or more large three-light frames, and three feet and a half deep, to contain that substance of bark, and may either be sunk half way in the ground, or not so much, according as the soil is dry or wet; but it would be most convenient to have it not sunk more than a foot, for the advantage of adding a lining of hot dung to the sides, if there should be occasion; I would, therefore observe, that a planked pit, for the culture of Melons, may be rather preferable to brick or stone, because if you shall find it necessary to line the beds, by applying hot dung against the outside of the planking, its heat will readily penetrate sufficiently to recruit the declining heat of the bed; for as the Melons are to be planted in the full bed, and not in pots, as practised to pine-apple plants, there is no stirring up the bark to revive the heat as in stoves, and a lining may probably be necessary to those beds, where cast-off bark is used, or perhaps sometimes one lining to those beds made of new tan, may be of advantage, just when the fruit is setting and taking their first growth; on these considerations contrive the pit so as to admit of lining the sides almost or quite to the bottom.

The time of year to begin the culture of Melons in these sort of hot-beds, is the same as mentioned in dung hot-beds, and the plants should be raised in a nursery-bed as there directed; and when of the proper age and size, as there observed, transplant them into the bark-beds to remain to fruit.

These fruiting-beds should be made a fortnight or three weeks before-hand, to acquire a proper heat in due time for the reception of the plants from the nursery hot bed, at their proper period of growth. Let the beds be made the full width and length of the pit allotted for them, and three feet at least deep; but if cast-off bark is used, three and a half depth in bark will be requisite. As soon as made, cover the bed with the proper frames

and glasses, to defend it from rains; and in about a fortnight it will be arrived to a proper temperature of heat; then earth it at top, as directed for the dung-beds, and the earth being warm, set two plants with their ball of earth entire, just under the middle of each light, give a little water, and manage them according to the former directions.

But if the bed is to be made mostly of cast-off bark, as it will be somewhat of a mouldering texture, and of but moderate heat, instead of earthing it as above observed, you may try the success of planting intirely in the bark, without any earth at all. Let the bed be of the above mentioned dimensions, and covered with the frames and lights, and in about three weeks it will be warm enough either to receive seed, or plants, first making holes in the middle of the bed, one immediately under the middle of each light, six or eight inches deep, and twelve or fifteen broad, fill them with rotten or finely pounded bark, forming each a little hollow, basin-like, in which either sow seed, and when the plants are a week or two old, thin them to two of the best in each hole, and there let them remain to fruit: or, to make the most of the bed, put in plants raised to a proper age, as in the dung hot-bed culture.

The plants being transplanted into either of the above bark hot-beds, observe the lights are to be kept constantly on, being careful to give the plants a proper share of warm air at all opportunities, as the weather permits, according to the former rules.

It must be remarked, that the plants will not require much water in these hot-beds, as bark continues to support a fine moist heat, of a very agreeable nature to the growth of most sorts of plants, so that the Melons will be found to succeed with a very moderate supply of water, and the less the better, both for the continuance of the heat of the beds, as well as for the advantage of the plants and fruit.

Should you find the heat of the beds considerably declined when the fruit is setting, or taking its first growth, a good lining of hot dung against the outsides of the pit will be very beneficial.

Saving the Seed.

As to saving Melon seed, we need only farther observe here, that it should be saved only from the very finest fruit of the respective varieties, and such that has a firm and highly

highly flavoured flesh; this should be particularly observed when the fruit is served at table, and the right seed properly reserved in its own pulp, and sent to the gardener; which, after lying in the pulp a few days, may be washed out, and all the heavy or good seed which sink in the water are to be preserved, dried, and put up for saving.

It will retain its germinative property ten or twelve years, but when from about three to five years old, is in its best perfection for use, for reasons already given.

CUCURBITA, the Gourd and Pom-pion, and also the *Citrullus* or Water Melon.

The plants are herbaceous annuals, mostly of trailing growth, extending from about five or ten, to forty or fifty feet in length, adorned with luxuriant simple foliage, and large monopetalous bell-shaped flowers, succeeded by enormous fruit, and are cultivated in our gardens, some by way of curiosity or variety, and some for the sake of their fruit, particularly the Water-Melon. See CUCURBITA CITRULLUS.

Class and order, *Monoecia Syngenesia*.

Characters.] CALIX, male and female flowers apart, having a monophyllous bell-shaped cup, terminated at the brim by five bristles. COROLLA, is monopetalous, bell-shaped, five-parted, and adheres to the calix. STAMINA, in the males, three connivent filaments, and linear reptant antheræ. PISTILLUM, a large germen under the female corolla, a conical, trifid style, and a large trifid stigma. PERICARPIUM, a large fleshy fruit of three membranaceous cells, and numerous compressed obtuse seeds, in a double series.

We shall first exhibit the Gourd and Pom-pion tribe under one head, and the *Citrullus*, or Water-Melon, in another. See CUCURBITA CITRULLUS.

Of the Gourd and Pom-pion kinds there are about five species, each of which admitting of several varieties in the form and size of their fruit; some assuming a long figure, obtaining from about two to five or six feet in length, and one or two round; others assume a round form, and as large as a half peck, or even a peck, or almost a half bushel measure, and other various forms and magnitudes down to the size of an orange; and the plants grow so rapidly, that rising from seed in spring, extend from about five or ten, to forty or fifty feet each way by August and September, at which times they perfect their

fruit, and in October and November following they totally perish; so that they are of but little more than six months duration. They are exotics of America, and other distant countries, but are hardy enough to grow here in the full ground, from May till October.

The species are,

¹CUCURBITA *Lagenaria*.

Bottle Gourd.] Cucurbita with trailing, thick downy stalks, branching into many spreading runners, extending along the ground fifteen or twenty feet in length, large, roundish, heart-shaped, indented, woolly leaves, glandulous at the base, and large white flowers, succeeded by long incurvated whitish yellow fruit, obtaining from about two to five or six feet in length, and about nine to eighteen or twenty-four inches round, having a ligneous durable shell, that having the pulp scooped out, is used for holding water, &c. hence the name *Lagenaria* or Bottle-Gourd.

Varieties of this are] Common long-fruited Bottle-Gourd—Long protuberant bellied Bottle-Gourd—Long sickle-shaped Bottle-Gourd—Long taper Bottle-Gourd—Long turbinated Bottle-Gourd.—All these varieties if forwarded in spring in hot-beds, and planted out in May into the natural ground, or rather upon holes of hot dung under hand glasses, to be sheltered during the cold weather; the fruit will obtain a large growth, and ripen perfectly. Some of which have acquired such a prodigious magnitude, as when scooped, the shell has contained twenty-two gallons of liquid; and in America, where they grow in great abundance, the shells are converted into many useful domestic utensils. The fruit, while quite young and tender, is also very commonly used in both Indies as culinary dishes, both to eat alone, and as sauce to flesh meat.

²CUCURBITA *Pepo*.

Pepo or Pom-pion, commonly called Pumpkin.] Cucurbita with trailing, strong, rough stalks, branching into numerous runners, spreading along the ground, from about ten to forty or fifty feet each way, garnished with large, roundish, lobated, rough leaves, and yellow flowers, succeeded by large, round, smooth fruit, of different forms and sizes in the varieties, some as big as a peck, or almost a half bushel measure, others considerably less, and some not bigger than an orange, ripening to a yellow, and sometimes a whitish colour, &c.

Varieties

Varieties of this are] Common large round-fruited yellow Pompion—Oval yellow Pompion—Oblong yellow Pompion—Whitish fruited Pompion—Marbled Pompion—Small round Pompion—Orange shaped Pompion—Pear shaped Pompion—Turbinated Pompion—Spherical, or semi-globular Pompion—Egg shaped Pompion—Striped roundish Pompion—Striped egg shaped Pompion—Striped turbinated Pompion—Striped pear-shaped Pompion.

This species and varieties are the most hardy, as well as considerably the most extensive in their growth, as a single plant, if properly encouraged, is supposed will overspread ten or fifteen rods of ground, and produce a great number of fruit; which, when young, is generally a mixture between a deep blue and pale white, but change as they encrease in volume. The plants are cultivated in England principally for curiosity, the fruit being rarely used; though in America, Asia, and Africa, these, as well as the Gourd, make great part of the food of the poorer people during the hot months; and, if gathered when not much bigger than a hen or goose egg, boiled and properly seasoned with butter, vinegar, &c. they eat tolerably palatable by way of sauce to butcher's meat; they are also used in soups; but here in England they are seldom used till grown to maturity, when they make a hole on one side, and divest the pulp of all the seeds, then mix it with sliced apples, milk, sugar, some grated nutmeg, &c. and thus make a kind of pudding, prepared in the shell, and bake it in an oven, which is commonly called pumpkin pye, and for which purpose the plants are cultivated by the country people in many parts of England, who plant them upon old dung-hills, or compost heaps, or such like places; for the seed, if not sown till May, will grow in the open ground; however, to have them in more early perfection, it is best to forward them in a hot-bed in April, and plant them out in the middle of May. See their *Culture*.

³CUCURBITA *Verrucosa*.

Warted Gourd] Cucurbita with trailing stalks, very branchy and spreading, running upon the ground ten or fifteen feet each way, large lobated leaves, and yellow flowers, succeeded by roundish, knobby-warted, white fruit, of different forms in the varieties; and all of moderate size.

Varieties are.] Roundish Warted Gourd—Oblong Warted Gourd—Flat Warted Gourd—Bottle-shaped Warted Gourd—Orange-

shaped Warted Gourd—Lemon Warted Gourd.

These varieties are also all used, while growing, as culinary, in many parts of America.

CUCURBITA *Melopepo*.

Melopepo, or Erect Gourd, or Squash.] Cucurbita with an erect strong stalk several feet high, rarely sending forth side runners, but becoming bushy upward, adorned with large lobated leaves, and the flowers succeeded by depressed knotty fruit, both of white and yellow colours, and of different forms in the varieties, but chiefly of a moderate growth.

Varieties are] Common broad flat Squash—Buckler-shaped Squash—Conical Squash—Citron-shaped Squash—Flat-sided Squash—Turbinated Squash—White-striped Squash—Yellow-striped Squash—All of which varieties grew with erect stalks; observing, however, that by saving the seed several years in the same ground, they are apt to vary, and assume a trailing growth, and put forth runners like the other species. The fruit when nearly half-grown, being boiled, is by some people esteemed very delicate; but the Americans generally pluck it for use soon after the falling off the flower, or when the fruit is the size of a walnut, or at most not bigger than a hen's egg.

CUCURBITA *Lignosus*.

Ligneous-shelled Gourd, often called Calabash.]

Cucurbita, with trailing stalks, branching into runners, extending many feet each way, large, lobated, rough leaves, and yellow flowers, succeeded by roundish moderate sized smooth fruit, of different forms in the varieties, and the shells become hard and woody.

Varieties of this are.] Roundish bottle shaped ligneous Gourd, being almost the size and shape of quart bottles—Pear shaped fruit—Orange-shaped yellow fruit.

Among the varieties of the last four species, there are some whose fruit are of the size, shape, and colour of oranges, lemons, and pears, which appear extremely curious when growing. These are commonly denominated—Smooth yellow Orange Gourd—Rock or carbuncled Orange Gourd—Stone-coloured Orange Gourd—Lemon Gourd—Rock Lemon Gourd—Yellow pear-shaped striped Gourd—Pear-shaped white-striped Gourd, &c.

But it must be observed, that the varieties of all the species of Cucurbita are amazingly variable in their fruit; that without particular care in cultivating them separate, they seldom

continue the same longer than two or three years; for those of each species vary less or more from seed, both in figure, size, and colour.

The plants in general have strong, thick, succulent stalks; the leaves very large, elevated on long foot-stalks, arising alternate from the joints of the stalks and branches; and the flowers are male and female apart on the same plant, proceeding from the axillas of the leaves, and the germen of the female flowers becomes the fruit. See the *Characters*.

All these species of Gourds and Pompions, &c. and respective varieties, obtain estimation principally as plants of curiosity, for the singularity of their growth and fruit, and are often admitted in curious gardens, both as plants of variety and ornament; and as such, if properly disposed, will exhibit a singular appearance, raising them in a moderate hot-bed in April as hereafter directed, and transplanted into different parts towards the middle or latter end of May, allowing them an open sunny situation; so that some may be disposed in open vacant spaces contiguous to lawns and spacious walks, training some along upon the surface of the earth, according to their natural growth, others may be trained about tall stout stakes fixed securely in the ground, and some may be conducted over bushes, or up the stems of shrubs and trees, and their course directed among the extreme branches. They have likewise a fine effect when trained upon arbours of lattice work, or railing, which they will soon overspread; and they also form a fine variety trained against a wall, paling, or any kind of fence; in all of which methods of training they will bear plentifully, but the fruit is the most conspicuous and ornamental when the plants are trained upon some kind of support, which is more particularly necessary to be practised in all those sorts denominated Gourds.

As the plants in general delight in a fat soil, they, when planted on old rotten dung-hills, generally make amazing progress, but more particularly the pompion kinds, where they will spread wonderfully, and produce abundance of fruit in its fullest perfection.

But the Bottle-Gourd, Warted-Gourd, Melopepo or Squash, and the Ligneous Gourd or Calabash, are commonly the most fruitful when trained upon some support, and the fruit obtains the largest size, and more especially the Bottle-Gourd.

As the fruit of these plants are but of little estimation in England for culinary uses, our gardens furnishing many other esculent plants, roots, and fruits, of a more palatable flavour; a few plants of each sort should, therefore, only be cultivated, because they require so much room to spread.

Their Propagation, Culture, &c.

All the species of Gourd and Pompions, and their respective varieties, are raised from seed sowed annually in April and beginning of May, either by aid of artificial heat, or without; but the plants forwarded in a hot-bed till about a month old, come into fruit a month or six weeks earlier, and will ripen sooner in proportion.

Therefore, the seed may either be sown in a moderate hot-bed in April, half an inch deep; and when the plants have three or four leaves, transplant them in May or early in June into the open ground, or upon holes of hot dung, under hand-glasses, &c. which will forward the plants considerably.

Or for want of hot-beds, the seed may be sown in the full ground in the first or second week in May, but not sooner. The *Cucurbita Pepo*, or Pompion, in particular, succeeds rather better than any of the sorts by this method; the third, fourth, and fifth species will also sometimes succeed tolerably in fine dry seasons; but the first species, *Cucurbita Lagenaria*, rarely ever comes forward enough to produce any tolerable sized fruit, unless forwarded at first by artificial warmth, and indeed all the other sorts of Gourd arrive much sooner to perfection, if brought forward at first in a hot-bed. However, in default of such conveniences, the seeds may be sown at the above mentioned times in the natural ground, where it is designed the plants shall remain to fruit, chusing rich ground in a sunny exposure, which should be well dug and formed into shallow holes, basin-like, as for the pickling cucumbers, at considerable distances, sowing three or four seeds, half an inch deep in each hole; but, if you have any hot dung to spare, it would be of much advantage, that in the places where you intend sowing the seed, to dig holes two feet wide, and fifteen inches deep, fill them with the hot dung, and earth it over six or eight inches deep, so forming the earth hollow, put in the seed as above; then, in either method of sowing, if there are any spare hand-glasses, it would also be of much service

service to place one over each hole occasionally in cold nights and bad weather, or for want of these, may cover on nights with large garden pots, &c. whereby the plants will come up sooner, and continue a surer growth than if fully exposed, observing to leave only one of the best plants in each hole, giving plenty of water in dry warm weather, and they will spread themselves considerably in June and July, and produce ripe fruit in August and September.

But, as the principal merit of all these sort of plants consists in their fruit, both for use and ornament, therefore, to have them in fruit as early as possible in summer, I should advise, where convenient, to sow and forward the plants in a hot-bed; that is, sow the seed in April in any of the cucumber or melon hot-beds, under glasses, &c. or, if sown separate in a moderate hot-bed under a small frame, or hand or bell-glasses, or oiled paper lights, they may be more readily hardened by degrees to the full air; and when the plants raised in either method are come up a few days, and have expanded their seed-leaves, they should be taken up and pricked down, either in the earth of the bed, about four inches distant, or rather in small pots, one plant in each, so plunging them in the bed; being careful, if in a bed by themselves, to admit a large portion of free air every mild day, to strengthen and harden them gradually, preparatory to their transplantation into the full ground, which is to be effected in May or early in June, when the plants have three, four, or five leaves, previously digging the ground, and forming shallow holes a foot wide, in the allotted places, and transplant the plants with a ball of earth about their roots, one plant in each hole, giving directly some water; and, to the tender sorts, the occasional shelter of a hand-glass, &c. on nights during the cold weather, will prove beneficial to the plants; let them, however, at any rate, have occasional shade the first week from the noon-day sun.

As, however, the first species, *Cucurbita Lagenaria*, is rather more tender than the other sorts, it would be highly proper in transplanting them, as above, where they are finally to remain, to indulge them still with a farther aid of artificial heat, and occasional shelter of glasses, otherwise they rarely come forward enough to produce fruit of any considerable size; therefore, in the allotted places dig holes two feet wide, and one and a half

deep, filling each hole with hot dung, and earth them six or eight inches deep, put in the plants, and cover them with hand-glasses till their runners advance from under them, managing them nearly as directed for the hand glass crop of cucumbers.

I would likewise observe, that as the Wart-ed-Gourds, &c. are also rather of more tender quality than the Pumpions, it is therefore also adviseable, where there is hot dung and hand-glasses to spare, to treat them in their final transplantation as directed above for the *Cucurbita Lagenaria*, by which practice you will obtain them in fruit much earlier in the summer.

All the sorts of these plants require a plentiful supply of water in dry weather, especially after they have begun to run. Let them, therefore, be duly supplied in dry seasons, and they will extend to a greater distance, and produce a great quantity of fruit.

When these fruit are designed to be used as culinary, for boiling, they should be gathered when quite young, while the outside tegument, or rind, is perfectly tender, they will then boil exceedingly soft, and have an agreeable flavour.

To save seed of these species, it must be taken from the ripe fruit in autumn; the finest and the most perfect ripened fruit of August and September should be chosen, and the seeds divested of the pulp, as observed of the cucumbers and melons.

Second Head.

CUCURBITA-CITRULLUS, the Citrul, or Water-Melon, (*Citrullus*.)

The *Citrullus* is now retained as a species of *Cucurbita*, according to the Linnæan arrangement, which by Tournefort, Miller, and other former botanists, was considered as a distinct genus, under the title of *Anguria*; but its characters being proved the same as the *Cucurbita*, or Gourd, it is properly a species of that genus.

Class, order, and character, the same as the *Cucurbita*.

There is but one species, viz.

CUCURBITA Citrullus.

Citrul, or Water-Melon.] *Cucurbita*, with trailing slender stalks, branching into many runners, extending six or eight feet every way, ornamented with large leaves divided into many parts; and yellow male and female flowers apart, the females succeeded by large round smooth fruit, replete with a watery cooling

cooling juice; hence denominated Water-Melon.

Varieties of this are] Large round red-fleshed Water-Melon—Large round white-fleshed Water-Melon—Large oblong Water-Melon—Small round Water-Melon, &c.

The large varieties of this fruit obtains a monstrous volume, frequently growing as large as half peck and peck measures; but these very large kinds rarely ripen in any degree of perfection in England; the most proper sorts, therefore, for English culture, are the small round kinds, which will ripen freely, and acquire a rich flavour, and of which there are both red and white fleshed kinds.

The plants are tender herbaceous annuals from the hot parts of the world, and nearly of the temperature of the *Cucumis Melo*, or Musk-Melon, and, like them requiring the aid of artificial heat and shelter, to bring the fruit to perfection in this country.

Their season of ripening in England is August and September.

These fruits by their cooling and diuretic quality are so very beneficial in hot climates, that they are greatly cultivated in Portugal, Spain, and the Levant; also in Persia and Egypt, and other parts of Asia and Africa, and the warm parts of America; in all of which countries they grow freely in the open ground, and ripen in the greatest perfection.

In England, however, notwithstanding our aids of artificial heat and shelter, this fruit, on account of its watery quality, and sometimes for want of proper culture, according to its nature, is often ripened but indifferently, which is the cause of its not being in general esteem. But by aid of substantial hot-beds, under constant shelter of frames and glasses, and the beds supported in a constant good heat, the fruit may be ripened in full perfection; which, if effected in due time in autumn, whilst the warm weather continues to give it flavour, it is very delicious eating, and is accounted exceeding wholesome.

Propagation and Culture.

The propagation and culture of all the varieties of *Citrullus* is nearly the same; as for the musk-melon, they are raised annually from seed sown in hot-beds, under frames and glasses in February or beginning of March, as for the musk-melons, and when the plants have come up a few days, prick them in pots (thirty-twos) two plants in each, plunging

them in the bed, observing to stop the plants also at the first joint; and when they begin to shoot runners, transplant them into a large hot-bed, also under frames and lights, where they are to remain to fruit.

As these plants are nearly of the same temperature, and nature of growth as the cucumber and musk-melon, the same degree of hot-beds, method of sowing, raising, and nursing the plants, is here to be observed; and their whole management, in respect to giving air, covering the glasses on nights, giving water, and supporting the heat by linings, &c. is also exactly the same. The ridging out the plants into the fruiting hot-beds is also the same as the musk-melon, observing to make the hot-beds substantial, for one or more of the largest three-light frames; for, as the plants spread considerably, should have as much room as possible; earth the bed twelve or fifteen inches thick in hillocks; but as one hole of plants is sufficient for each, a three-light frame, therefore, lay only one hillock of earth just under the middlemost light, earthing the other parts only about three inches thick at present, so when the earth is warm, put in one pot of two plants in each hill of earth; though one plant, if it thrives, will sufficiently fill the frame, for they spread at a great rate, and unless they have full scope, they will make little progress in fruiting.

When they are thus ridged out, observe that as the glasses must be continued constantly on the frames, do not omit giving air at all opportunities, agreeable to the rules exhibited in the cucumber and melon same culture; likewise cover the glasses every night with mats as for them directed; give also frequent moderate waterings, and earth the bed gradually to the depth of the hillock on which the plants stand, and conduct the vine and runners in proper directions, so as to fill all the places within the frame. The heat of the bed must also be supported with great attention, by proper linings of hot dung; observe this all along, to forward the plants as much as possible, and it is particularly necessary, when the plants begin to shew fruit, and whilst it is taking its first growth, until almost as big as a man's double-fist, for without a constant bottom heat till that period, it will be impossible to bring this kind of Melon forward enough to ripen in good perfection in England; therefore, let it be a rule to maintain a constant heat in the bed, as above,

above, and continue the constant shelter of the glasses, tilting them all fine days, to allow a proportionable share of air; and in scorching sunny weather, a slight shade of a mat, or a little loose hay, for two or three hours in the middle of the day will be necessary, together with a moderate portion of water once a week or fortnight; and with this culture, the fruit will readily attain perfection in any part of Britain, and before it is late in autumn; for unless they ripen in August and September, they will be devoid of flavour.

The aid of bark hot-beds would be very beneficial in the culture of this species, as we formerly observed in the musk-melon culture.

It must be remarked, that these plants can never be fruited in any degree of perfection under hand or bell-glasses, &c. as practicable for the latter crops of musk-melons.

With respect to the tokens of ripeness of these fruits, it must be remarked, that they seldom impart that very fragrant smell peculiar to musk-melons, nor, like them, do they often crack or recede from the footstalks; but they sometimes change a little yellowish, and the top becomes soft or pliable to the touch, and by smelling close to that part, they sometimes also discover their maturity by the emission of a little fragrance.

The saving seed of this species is, as observed of the Musk-Melons, to be effected always from the finest and most perfectly ripened fruit, treating it in the same manner.

CULINARY Plants. Plants or herbs that are used in the kitchen for boiling, stewing, or any other culinary purpose in cookery.

CUPRESSUS, the Cypress Tree.

This genera consists of hardy evergreen and deciduous trees, of beautiful pyramidal growth, and are proper both as timber trees, and for ornamental plantations, being very picturesque in their general habit, extending their branches regularly all around from top to bottom of the stem, closely decorated with small narrow thick leaves, and amentaceous male, and conous female flowers, succeeded by round scaly fruit, called cones. See **CONUS**.

Class and order, *Monocelia Monadelphia*.

Characters.] **CALIX**, male and female flowers apart on the same plant; the males an oval katkin, and the females a roundish cone, each of several scales, and each scale serving as a calix to one fructification. **COROLLA**,

no petals; **STAMINA**, no filaments, but four antheræ at the bottom of each scale. **PISTILLUM**, a scarcely visible germen, and very short style. **PERICARPIUM** none, the seed being involved only by the tough scales of the calix, forming a roundish cone.

There are about three distinct species of these trees common to the British gardens, two evergreens and one deciduous; and one of the former admits of three beautiful varieties, differing in stature and habit of growth.

The species are,

CUPRESSUS Sempervirens.

[*Evergreen Common Cypress.*] **Cupressus**, with an upright strait stem, closely branching all around almost from the bottom upwards, into numerous quadrangular branches; obtaining, in the different varieties, from about fifteen or twenty, to forty or fifty feet stature, and very closely garnished with very small, narrow, erect evergreen leaves in imbricatum, and flowers and fruit from the sides of the branches.

Varieties of this are,

Evergreen common upright Cypress—arising from about fifteen to twenty feet high, and with all its branches assuming an upright direction, often growing in a close pyramidal form.

Evergreen horizontal spreading Cypress—arising thirty or forty feet high, and with all the branches spreading widely in a horizontal direction.

Evergreen small-fruited Portugal Cypress, often called Cedar of Goa—obtaining near twenty feet stature, having all its branches spreading irregularly in a somewhat horizontal position, frequently bending downwards, and the leaves ending in spines.

All these varieties of *Cupressus Sempervirens* are inhabitants of the Levant, and grow in great abundance in Spain and Portugal, also in the island Crete, or Candia, where there are vast plantations of them, and are used as their most common timber, more particularly the horizontal kind, as being the largest grower, the timber of which is supposed to be of many hundred years duration in any kind of buildings, for it is said to resist the worm, moth, and all putrefaction. The trees in general are also beautiful, in their growing state, and so hardy that they prosper here in almost any soil, but are observed to be particularly thriving in any gravelly or sandy ground, and may be employed to great advantage in ornamental plantations for the embellishing gardens

dens and parks. The first of these varieties was long the most common in England, and on account of its erect close pyramidal growth, was formerly trained into regular figures, by shearing it annually in summer.

²CUPRESSUS *Thyoides*.

Thyoides, or *Evergreen arbor-vitæ-leaved American Cyprus*, sometimes called *White Cedar*.] Cupressus, with an upright stem, branching out regularly into numerous ancipal, or two edged branches, and arises twenty or thirty feet high, ornamented with flat evergreen leaves, imbricated like arbor vitæ, and small blue cones the size of juniper-berries.

CUPRESSUS *Disticha*.

Distichous-leaved American Deciduous Cypress.] Cupressus, with an erect trunk, attaining a large bulk, branching wide and regular, and grows fifty or sixty feet high, fully garnished with small spreading deciduous leaves, arranged distichous, or along two sides of the branches. And, considered as a deciduous tree, makes a most beautiful appearance in summer.

The flowers of all these trees arise principally from the sides of the branches, but they make but little appearance, and the fruit is universally smallish, close, round cones, which, on large trees, sometimes ripen in England, though not always furnished with good seeds, so they are commonly procured from abroad for sowing.

All these trees being beautiful in their general growth, and very ornamental in their small, but closely placed foliage, are most proper to be employed in all ornamental plantations, and have a fine appearance either thinly grouped with other trees, on the sides of spacious lawns, or to border grand plantations; likewise to assist in forming detached clumps, or to be stationed here and there as single objects, or in small groups by themselves, of from two to five of different sorts, in extensive lawns, parks, and other grass ground; they are also choice furniture to be employed in assemblage in forming rural avenues, and grand rural walks, and the evergreen kinds, by their pyramidal form, are peculiarly adapted for embellishing the grounds contiguous to ornamental garden buildings, temples, and other sacred structures, in any part of pleasure grounds; and single trees placed in large breaks or opens, in the excursions of spacious serpentine walks are very ornamental.

As some of the sorts acquire a considerable

stature and bulk, and arrive to timber, they may also be introduced among forest trees, in the most conspicuous parts of estates, to the emolument of the owner, as well as to improve the beauty and elegance of his plantations.

The season for planting, or transplanting these trees is the same as for other hardy evergreens, and those of the deciduous tribe. See EVERGREEN and DECIDUOUS TREES.

In their culture it is advisable to suffer them all to retain their natural growth, in which they will exhibit the more picturesque appearance.

Propagation of all the sorts.

They are all raised abundantly by seeds; they will also sometimes grow by cuttings of the young shoots, but the seedlings make the handsomest plants.

The seeds are procured in their cones from the seeds-men, and by exposing them to a moderate heat, they readily open and discharge the seeds freely. The season for sowing them is any time in March, and they grow freely on a bed, or border of common light earth, especially the first and third species. Let the ground be then dug, well broken, and raked smooth, then drawing an inch of earth evenly from off the surface into the alley, sow the seeds moderately thick, and directly sift the earth over them, half an inch deep. The seed being thus sown, observe, that, if in April and May the weather proves warm and dry, a very moderate watering will be now and then necessary, and the plants will rise in six or eight weeks; observing then, and during summer, to keep them clear from weeds, and in dry weather give them gentle waterings twice a week. In winter indulge them with occasional shelter of mats in time of hard frost. Thus continue your care till the second spring after they come up, when they will be two years old; then in March or April transplant them from the seed-bed into a sheltered situation, in nursery rows two feet asunder: and in three or four years they will be fit for the shrubbery, &c.

But if the seeds of these trees were sown in pots, tubs, or boxes, and plunged in a moderate hot-bed, under occasional shelter of mats, the plants will come up near a month sooner than those in the full ground; and they may be pricked out the following spring into the nursery.

As

As the *Cupressus Thyoides*, however, is sometimes a year after sowing before the plants come up, it may therefore be proper to sow the seeds in boxes, pots, or tubs, for the conveniency of removing them to the shade, to have only the morning sun during summer, and to a sheltered sunny situation in winter; and if the plants should not appear the first year, it would be of great advantage, in spring following, to plunge them in a hot-bed, as above observed; it will greatly forward the plants, so as to be fit to transplant the spring following.

Propagation by Cuttings.

This may be tried upon all the sorts, tho' as to the evergreen kinds, it is often two years before they are properly rooted. Chuse the young shoots, plant them in October, in a sheltered situation, and give plenty of water the following summer. But the plants raised from cuttings will not obtain more than half the stature of those raised from seeds.

CUTTINGS. In gardening, Cuttings are a part of the branches of plants and trees, cut off and planted for the purpose of propagation.

Vast numbers of trees and plants may be increased by Cuttings; for, as a branch, or even the smallest twig of one, may be considered as a part similar to the whole plant, and that when separated, or cut from its parent, is devoid of a root, yet, being planted in earth, it in process of vegetation forms one, as well as advances with a stem furnished with branches, and exhibits leaves, flowers, and fruit, exactly the same as the mother-plant, without the least variation.

Some sorts of plants are also propagated by Cuttings of their leaves, as in some sorts of *agave* and *aloe*.

Numbers of trees grow so readily by cuttings, that it is the only expeditious method for raising them; as for example, the willow, poplar, and alder, which will grow either by small Cuttings, of six inches or a foot long, or by large truncheons, a yard or more in length, and as thick as a man's wrist. And of the willow, Cuttings of the large branches, two or three yards long, and two or three inches thick, planted in moist places, will readily grow.

But the proper parts of most other trees, shrubs, and herbaceous plants for cuttings, are principally the young shoots of one, or at most two years growth, though most trees

and other plants succeed best by the one year's Cuttings, and planted in the autumn or spring after they are produced; and some sorts of hard wooded plants succeed best by planting the same year's shoots in summer, as is observed under their respective articles.

The proper lengths to take off the shoots, as Cuttings, are various, from about three or four to twelve, fifteen, or eighteen inches long, according to the nature of the plant, length, size, and strength of the shoots, of the respective sorts; all of which is explained in the culture of all the different kinds that are propagated by this method, each under its respective genus.

In choosing the Cuttings, always prefer shoots of the most robust growth, according to their nature, to the long, rambling, weakly shoots: prefer also those that are freest from side shoots; and in taking off the Cuttings, that, if they are of the smaller, ligneous, shrubby plants, such as the wall-flower, southernwood, sage, and the like, they may be slipped off with the hand from the side of the branch, though these are more properly slips than Cuttings. See **SLIPS**. And many of the smaller sorts of shrubs, both deciduous and evergreens, may be taken off in the same manner; but those of the strong-shooting shrubs and trees, and all succulent plants, should always be cut off, either from the side of a branch, or from the end of one, or the end of a former year's shoot, as is convenient. In taking off cuttings, it is often recommended to cut them with an inch or two of the former year's wood adhering to their bottom, particularly the vine, laurel, and several others, which may be practised where convenient; but most shoots that will grow by cuttings, succeed equally well without any of the old wood.

In preparing Cuttings previous to planting, trim off all side shoots; and all those which have weak, tender, crooked, or straggling tops, as often occur in many of the deciduous tribe, should be topped, or shortened down to the firm straight wood; though those that have straight robust tops, according to their nature, may remain entire, particularly the evergreen kinds, and never top any Cuttings of succulent plants.

Many sorts of trees and shrubs that propagate by Cuttings, make very long one year's shoots, often long enough to admit of dividing into several lengths for cuttings of ten or fifteen inches each, as in the vine, honeysuckle, jasmine, passion-flower, with many other decidu-

deciduous climbers, and other trees; but I would observe, that the bottom part of these shoots that are firm and well ripened, cut off from about eight or ten to fifteen inches long, are the most eligible for Cuttings; though the upper parts, if they have ripened to a tolerably firm texture, may, in cases of scarcity, be also used in lengths as above, rejecting the weak straggling part toward the upper end; but the lowermost Cuttings generally make the best plants.

All Cuttings of trees, shrubs, and plants, that are not succulent, should be planted as soon as possible after cut from the parent plant. But as to succulent Cuttings, they being mostly very replete with moisture, that when separated from the parent, the moisture continues to issue abundantly, often for several days at the cut part made in separation, therefore, until that part is dried and crusted over, it is not proper to plant them, otherwise the moisture flowing out, would cause them to rot in the earth.

With respect to the mode of planting, most Cuttings of trees, shrubs, and all other plants, not succulents, should be planted nearly two parts in three in the ground; but succulents should be only just put as far into the earth as to make them stand, and is sufficient to root; for if planted too low they are apt to rot, nor will they emit roots freely.

Some sorts of Cuttings grow freely in the common open ground; others require a shady situation, and some to be potted for occasional shelter; and others require the aid of a hot-bed, to promote their rooting, all of which is also fully exhibited accordingly, as the respective plants require, each under its proper genera.

Most sorts of Cuttings will be sufficiently rooted in one year, and some in one or two months, especially those sorts planted in hot-beds, and even sometimes in the full ground, when planted in the young wood in summer.

As to the season for planting cuttings, spring and autumn is the time for most sorts of trees and shrubs; and for herbaceous plants, such in particular as grow by Cuttings of their flower-stalks, as the scarlet lychnis, lychnidea, &c. and such as grow by young shoots from the bottom, as the carnation and pink, and those ligneous-herbaceous plants that grow by young shoots from the sides of the branches, as sage, rue, rosemary, wall-flower, often succeed best in sum-

mer, as soon as their shoots are of due size, in May or June, as is directed for each sort in its proper place; but most succulents in particular succeed best by planting their Cuttings in summer, from about the middle of May till August, and they will be well rooted before winter.

All varieties of particular species of all sorts of trees that grow by Cuttings, may, by that method of propagation, be continued distinct, the same as by grafting, budding, and laying; for the plant raised from a Cutting will be exactly the same as the parent, and can never vary like seedling varieties. See VARIETIES.

As there are numerous sorts of trees and shrubs, both deciduous and evergreen, as well as many succulent and herbaceous plants, which grow by Cuttings, they will be particularly mentioned in their respective places in their proper genus, and the particular method of managing each kind, in respect to their propagation by Cuttings, fully explained.

CYCLAMEN, Sow-bread, but commonly called *Cyclamen*.

This genus consists of many low, herbaceous, flowery perennials, of the tuberous-rooted tribe, consisting of a large, roundish, fleshy root, crowned by numerous, angular, and heart-shaped, spotted, marbled leaves, and many fleshy foot-stalks, six inches high, surmounted by monopetalous, five-parted, reflexed flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is roundish, five-parted, and permanent. **COROLLA** is monopetalous, with a globular tube, the limb or upper part large, and divided into five spear-shaped reflexed segments. **STAMINA**, five filaments and straight acute antheræ. **PISTILLUM**, a roundish germen, filiforme style, and acute stigma. **PERICARPIUM**, a globular unilocular berry, opening in five parts at top, and many oval angular seeds.

Modern botanists allow of but two species, one of which however admits of many beautiful varieties, and is the sort principally known in our gardens.

The species is,

CYCLAMEN *Europæum*.

European Cyclamen.] **Cyclamen**, with a large orbicular or compressed fleshy root, crowned by many angular and heart-shaped leaves, elevated about six inches on their own foot-stalks; and between them many fleshy

fleshy flower-stalks, of six or eight inches stature, terminated by reflexed flowers of different colours in the varieties, appearing in autumn, winter, and spring, succeeded by ripe seeds in June, July, and August.

Of this species are many varieties, all of the same habit of growth, size, and mode of flowering, only differing in the colours of the flowers, and time of appearing, and may be divided into three classes, the autumn, winter, and spring flowering, viz.

Cyclamen Autumnale, or Autumnal Flowering.

Common ivy-leaved autumnal white-flowered Cyclamen—ivy-leaved, autumnal, purple-flowered Cyclamen; both of these varieties having angular heart-shaped leaves, and which are generally marked with black in the middle, and the plants are very hardy—Round, heart-leaved, autumnal, purple Cyclamen; having large orbicular leaves, heart formed at the base, purplish underneath, and purple flowers with crimson bottoms, and the plants are rather impatient of severe frost, requiring either to be placed close under a warm wall, or in pots, to move to occasional shelter in winter. Of these varieties the two first are the hardiest and the most common in the English gardens; all of them flowering in August, September, and October; the leaves rising about the same time, and continue until May, then wither, and the seed bud lying close to the ground all winter, ripens in June.

Cyclamen Hyemale, or Winter Flowering.

Orbicular, plane-leaved, Winter Cyclamen, with bright purple flowers—Angular-leaved, flesh-coloured, Winter Cyclamen—white-flowered Winter Cyclamen.—All of which varieties flower towards Christmas, continuing six weeks; and the leaves appearing at the same time, continue till summer, then decay, and the seeds ripen in July; the plants being rather a little tender, should be planted on a warm border, and sheltered from frost, or some may be potted, to move to occasional shelter.

Cyclamen Vernal, or Spring Flowering.

Heart-leaved white Spring Cyclamen, having the upper side of the leaves veined and marbled with white, and white flowers with bright-purple bottoms—Angular, heart-leaved, purple, Spring Cyclamen, having the leaves veined and marbled with white, and purple flowers with crimson bottoms—With marbled leaves and red flowers—Marbled

leaves and entire white sweet-scented flowers—With yellow flowers, but rare;—all of which varieties flower in March, April, and May, being furnished with leaves at the same time, which continue till the beginning of June, then decay, and the seeds ripen in August. This class of varieties are more tender than the two former; they, however, will often succeed planted close under a warm wall, but it is also proper to have some in pots, to move to shelter of a green-house in winter.

The roots of all these plants are large, compressed, fleshy lumps, emitting fibres at their base. The flowers and leaves of all the varieties arise immediately from the root, on their own proper foot-stalks, about from four to six or seven inches high, one flower generally crowns each stalk, each divided into five segments, reflexed backwards; and when the flowers fade, their stalks shrink spirally to the ground and envelope the seed-bud, and sit close to the earth among the leaves, increasing to a large, round, baccaceous fruit; or seed-vessel, ripening, as before observed, in June, July, or August.

All the varieties, though of humble stature, are very ornamental, both in their variegated large foliage, and their beautiful flowers, some of which are very fragrant; especially of the vernal kind, which are also commonly the most beautiful; but all the sorts merit admission in every curious collection.

The two first autumnal varieties may be planted in any of the common borders; but all the other sorts should either be stationed close under a warm wall, and sheltered with mats, &c. in hard frost, or potted and placed in a frame or green-house for the winter. They should all have a dry light soil, otherwise the root is apt to rot by wet.

As the leaves of all the sorts decay in May and June, that is the only proper period for removing the plants either for increase by dividing the root, or to plant them into fresh prepared earth, or to transplant them from one place to another, &c. but as the roots do not lose their fibres, they should not be often removed.

Propagation, &c.

All the sorts are propagated by seeds, and the particular varieties by dividing their roots.

By seeds.—They grow freely in common earth, but it will be three, and sometimes four or five years before some of the seedlings

will produce flowers; there is, however, this consolation, that the flowers will be large and fine, and often some new varieties. Let the seeds therefore be sowed soon after they are ripe, at least, in August or September, in boxes, tubs, or large wide pots of rich light earth, and cover it half an inch deep; so place them to have only the morning sun till October, then placed in a warm sunny exposure, and at the approach of bad weather remove them under a hot-bed frame, to have occasional shelter of the lights, but expose them fully every mild day. By this care some of hardiest sorts will probably appear towards Christmas, or before, but all of them in spring, observing in warm dry weather to give moderate waterings till their green leaves decay in summer; at which time place them to have only the morning sun, as before, till October; then sift half an inch of fresh earth over the surface, continuing to defend them from frost in winter; and in summer following, when their leaves fade, transplant them where they are to remain, some in the full ground, and some of the tender kinds in pots, and in a year or two after some of them will begin to flower.

By dividing the roots—They make but small progress of increase by the root; however, the root may be divided by cutting it into two or three pieces, which must be done in summer, planting them again directly, and they will each flower at its respective season.

CYDONIA, the Quince Tree. See PYRUS.

CYNARA, Artichoke and Cardoon.

Of this genus are two eminent species for the kitchen garden, the Artichoke and Cardoon, both hardy herbaceous plants; the former perennial, and the latter rather biennial, in England.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] CALIX, compound flower, having a ventricose general calix, composed of numerous broad scales. COROLLA, numerous, tubular, hermaphrodite florets, each five-parted at top. STAMINA, five capillary filaments, and cylindrical antheræ indented in five parts. PISTILLUM, an oval germen to each floret, slender style, and oblong emarginated stigma. PERICARPIUM, none.—SEMEN, a four-cornered seed, crowned with down, succeeds each floret.

Of the garden Artichoke there is but one real species, and of the Cardoon the

same; but of the Artichoke there are two celebrated varieties.

The species of Artichoke is,

'CYNARA Scolymus.

The Garden Artichoke, formerly Scolymus.] Cynara, with large thick perennial roots, crowned by a considerable cluster of large pennatifid erect leaves, two or three feet long, and in the midst upright stalks a yard high, surmounted by a large, round, scaly head, being composed of numerous, oval, calycinal scales, enclosing the florets, sitting on a broad, fleshy receptacle, which, as well as the fleshy base of the scales, is the only eatable parts of the plant.

Varieties of this are,

Conical-headed green French Artichoke—having the folioles of the leaves commonly terminated by small spines, a tall stalk, the head somewhat conical, and of a light green colour, and with the scales pointed at top, opening and turning outward.

Globular-headed red Dutch Artichoke—having leaves without spines, a strong stalk, the head large, globular, a little compressed at top, and of a reddish-green colour, broad obtuse scales emarginated at top, growing close, and turn inward.

Of these two varieties the globular-headed kind is deservedly in most esteem, being considerably larger than the conical-headed Artichoke; and its eatable parts, both of the bottom and scales, are considerably more thick and fleshy, as well as more agreeably flavoured, and should therefore be principally cultivated both for family and market.

Both the varieties are perennial in root; but the leaves and fruit-stem die to the ground in winter, and their roots remaining, send up new leaves, and a supply of Artichokes every summer, for ten or twenty years, if required. The conical green-headed sort is rather the hardiest to resist the power of severe frost.

The flowers and seed of all the plants of this genus are produced in the centre of the head, the scales of which are the proper calix of the flower, which consists of numerous small bluish florets, succeeded by downy seeds, sitting naked on the receptacle.

The Culture; and first of their Propagation, and Method of planting.

Both the varieties of Artichoke are propagated always by slips or suckers, arising annually from the stool or root of the old plants

in spring, which are to be taken from good plants of any present plantation, in March or beginning of April, and planted in the open quarter of the kitchen-garden, in rows five feet asunder, all as hereafter directed, and they will produce Artichokes the same year in autumn, the same plants enduring many years, and produce a fresh crop annually in summer.

It however should be remarked, that although Artichokes are of many years duration, yet, their annual produce of fruit will, after the third or fourth year, be every season smaller, and less fleshy in the eatable parts; so that a fresh plantation should be made every three or four years: but, in order to obtain a longer succession of heads during each season, I should advise to make a fresh plantation annually, whereby you will have a regular supply of fruit several months, i. e. from June till November; for the old plants of one or more year's standing produce their heads in June and July, and are mostly over by August; at which time, the young plantation of the same year takes place, producing fine large heads, continuing to come in gradually till November: therefore, by planting a few every spring, that besides the long succession of fruit, you have always a crop ready to succeed the old ones, when you shall think proper to eradicate them; which, when intended, may be done in autumn, after they have yielded their summer crop; at which time, observing, that if you shall have occasion for many young plants as soon as possible in spring, some of the best of these old stools may, in October or November, be trenched in close together, in some dry warm place, under a hedge, or any fence open to the full sun, raising the earth up about the young shoots; and in winter, when hard frosts prevail, cover with long dung litter, and thereby you will have a chance of obtaining good plants for a new plantation, if the severity of the winter should destroy or much injure those in the open quarter; and even at any rate, they will furnish young plants sooner by a fortnight or a month, than the standing crops in an open exposure, especially if the winter has proved severe; so after having slipped off the best young shoots for planting, eradicate the old roots entirely.

The slips, suckers, or young plants, either of any standing plantation, or of the old roots above-mentioned, are generally to be taken off for planting in March, and sometimes in

very backward seasons, or after hard winters, it will be the beginning or middle of April, before they are large enough for that purpose, which should be from about eight or ten inches to a foot long. For the method of slipping or taking them off for planting, see the method *Of their Spring Dressing*.

With respect to situation and soil for these plants, they should have a free exposure; the more distant from spreading trees the better, which would draw them up weak; and as to soil, they prosper in any common soil of a kitchen-garden, capable of producing tolerable crops of other esculent plants, though they are the most prosperous in a somewhat moist soil; but, if possible, avoid planting them in wet ground, as in such the plants would be in danger of rotting, or subject to great injury in winter; and having fixed on the ground, lay thereon a considerable coat of rotten dung, spreading it equally over every part; then trench the ground one good spade deep, besides the top paring or shovelling, and each trench two spades wide, as you proceed, bury the dung equally in the bottom of the trenches.

The ground being thus prepared, then get the plants, such as above-mentioned, and prepare them for planting; observing to make choice of such of the shoots or suckers only that are best furnished with some fibres to their root; taking these one by one, cut off the hard knobbed part at bottom, rejecting such that are very tough and stringy, and trim the outer leaves down about one third or near half way, so as the central ones have full liberty to expand. Being thus trimmed, let them be directly planted by line and dibble, in rows five feet asunder, and the plants two feet distance in each row, putting each plant three or four inches deep in the ground, closing the earth well about the root and body of the plant as you proceed in planting; and immediately let every one be watered, for this will settle the mold close about them, fix every one firmly in its place, and promote their early rooting; observing, if the weather at this time proves dry, to repeat the waterings every three days, for a week or a fortnight, till they have taken fresh root, and begin to grow.

After this, they require no further culture during summer than to be kept clean from weeds, which is readily done by hoeing with a large hoe between the plants in dry weather.—And in the beginning of
winter

winter the ground must be ridged up along each row, to defend the plants from frost.

In making plantations of Artichokes, that if it is necessary to make the most of every piece of ground, as is consequently the case with the market gardeners, you may sow between the rows a crop of round-leaved spinach, with some short-topped radish, and a sprinkling of coss lettuce, mixing the seeds together, and sow them by broad-cast; then tread in the seed and rake the ground, for the Artichokes will soon get the start out of the way of these small crops, and when they come off in June, may plant a row of cabbage or favoys along the middle of each space between the Artichoke ranges, to come in for autumn service.

But the kitchen-gardeners in the neighbourhood of London frequently plant their Artichokes at such distance between the rows, as to have spinach, radishes, cauliflowers, pickling-cucumbers, and cabbage or favoys, all from the same spot. To do this, they allow ten feet between the rows of Artichokes, sowing the ground, as above, with spinach, radishes, &c. in spring; and at the same time plant in each space two rows of cauliflowers, at four feet distance, and two and a half apart in each row; and then, in the first week of June, when the ground is cleared from the radishes and spinach, they sow cucumbers for pickling between the cauliflower rows, and in June or July plant, in the intervals between the rows of Artichokes and cauliflowers, a row of cabbage or favoys; the cauliflowers coming off in July or early in August, there will be full scope for the remaining crops; and the cabbage and favoys coming in for autumn use, will be all gathered by the middle or end of November, time enough for landing up the Artichokes.

Their Culture when in Fruit.

The plants of the new plantation will begin to shew their fruit or heads the beginning of August, and will be in the fullest perfection from about the middle of that month to the latter end of September; and sometimes they continue fruiting gradually until November; but next year the same crop will come into fruit in June and July, and be mostly all over in August; so that, as already noticed, if you would continue a succession annually from June to November, always plant a few every spring, to come into fruit to succeed those of older plants.

But with respect to the care of the plants when in fruit, observe, that, besides the principal or top fruit, several collateral small heads often arise from the sides of the main stem, which side-shoots, or suckers, being displaced, the whole nourishment is consequently directed to the principal head; therefore if you prefer one large handsome head to three or four small ones, the above culture should be constantly practised, from time to time, before the side heads exceed the size of a hen's egg.

These small side-heads or suckers are by many greatly esteemed, being cooked in various ways, and served up to table; and the London gardeners having great demand for them, they gather them as they are produced, and tie them in bunches for market.

But some persons, not anxious about having very large heads, suffer the above-mentioned side-shoots to remain, rather preferring three or four middling ones, from the same stem, in successive order, than only one large fruit.

The maturity of the Artichoke heads, is, when arrived to their full magnitude, discoverable by the scales diverging from each other considerably, but before the centre or crown opens, to shew an effort for flowering.

When the heads are to be gathered, you should cut them with six or eight inches of the stalk at least; but if for market, almost three times that length.

But as the heads are gathered, the whole stalk should always be broken down close to the ground, being absolutely necessary to the welfare of the plants, by encouraging their stools to produce some new shoots more freely before winter.

In Covent-Garden and the other London markets, Artichokes are sold commonly from about two to three shillings per dozen, and sometimes at a little more or less, according to the kinds and size; but the globe kind is always the most saleable.

Their Winter Dressing, and landing up, to protect them from Frost.

The winter culture of Artichokes is principally to land or earth up the rows, to guard the crown of the root and young shoots from severe frost, which is done by digging the ground, and forming the earth into a ridge along each row over the roots, without which precaution, the inclemency of the winter

winter often proves destructive to those plants.

This work should be done towards the latter end of November, or beginning or middle of December, according as the weather continues more or less mild.

In the first place, cut down all the large leaves near the ground, preserving only those of the small young shoots; and this may be done any time in November; then at the time above-mentioned, proceed to dig the ground between the rows, and work it up close to the plants, in a sort of ridge, along each row. But the most regular way is, that if the plants are in close rows for a full crop, i. e. in rows five feet asunder, range a line exactly along the middle of each space between the rows, then with the spade chop the ground along according to the line; and thus you form beds five feet broad, one row of plants ranging along the middle of each bed; then dig the ground bed and bed a moderate spade deep, gradually working the earth from each side towards the middle in a ridge along the row of plants, as above observed, so as each row stand exactly in the middle of every such ridge of earth; rearing the earth close about the plants, but not quite over their tops; and this will greatly shield the crown of the root and young shoots from the effects of hard frosts.

But when the rows of Artichokes are ten feet distant, as in many of the kitchen-gardens, for the sake of obtaining other crops between, you may then either ridge up the plants, in five-foot wide beds, as above directed, or trench all the ground in the common way, in ridges two or three feet wide, ranging the way of the rows, and digging them one spade deep; and as you advance to each row of plants, land them up, by forming a good ridge along the row, that each row stand in the middle of a ridge of earth, as in the other method.

Some persons, however, instead of landing up the plants in either of the above methods, only draw a little earth, with a hoe or spade, up close about the plants, and at the approach of severe frost, add a covering of long dung litter, or some such like light material; and some never land, nor draw any earth about them at all, only mulch the plants in December, or towards Christmas, or sooner, if hard frosts set in, laying some shortish dry mulch about each hole of plants, bringing it close around about the shoots, and let it remain all

winter, till danger is past; either of which methods is indeed often sufficient in our ordinary winters; but as there is no knowing what weather will happen, so it is not always to be depended on; and there is nothing so effectual for the benefit of the plants, as ridging up the earth about them, as before directed.

Remember, however, that if the frost in winter should prove extremely severe, it is also adviseable to lay over each ridge a covering of any kind of long dry litter, which, together with the ridge of earth, will effectually secure the plants.

Likewise observe, that if hard frosts set in before you have time to land the plants, do not fail, in that case, to lay a thick covering of dry litter over them.

All coverings that have been occasionally used during hard frost, should be removed in February, or at least as soon as the weather breaks; and in March or beginning of April the ridges of earth should be levelled down, and the plants have their spring dressing as follows.

Their Spring Dressing, by levelling down the Ridges, and displacing the superabundant Shoots.

In March or beginning of April, according to the forwardness of the season, that the plants have made some tolerable shoots, the ridges of earth landed over them in winter for their protection, should be levelled down, and all superabundant and ill placed shoots cleared away, leaving only two or three of the most promising suckers upon each stool.

Taking opportunity of dry weather for this work, dig or level down the ridges of earth length-ways, row and row, stirring all the ground between and close about the plants; and as you proceed, remove the earth from about the crown of the root and young shoots, as low as the part of the stock from whence they arise; then, if there are several shoots, fix upon two or three of the straightest, most promising, and best situated on each root, toward the lower part of the stool, at some distance from each other; let all the rest be cleared away, by slipping them off close to the root, and directly draw in the earth again about the remaining shoots, closing the earth well around them, and press it gently between, to preserve them as far distant from each other as their situation will admit, and trim off any broken or dangling leaves; and in this manner

manner treat every stock, as you advance in digging or laying down the ridges, observing to level the ground in a neat manner; and if you chuse, the spaces between the rows may be sown with spinach, &c. or any light crop, as observed at the time of making the plantation.

But I would remark of this spring dressing, that if in March you find the stocks shoot weakly, occasioned by hard frost or much wet, it will be proper, only for the present, to open and loosen the earth, and level down the ridges a little, to encourage the roots; and in three or four weeks after, when they have made tolerable shoots, may slip them as above, and dig and level the ground properly.

The young shoots which are slipped off in the above spring dressing, are, as before observed, the proper plants wherewith to make new plantations; a proper quantity of the best should therefore be reserved, making choice of such that are straight, from about eight or nine inches to a foot long, and whose bottoms cut free and crisp, rejecting such that are very tough and woody at the base.

The sooner they are planted after being separated from the old plants the better; but if the ground should not be ready, lay them till then, by the roots in a trench, placing them upright, for if placed slanting they, by assuming an upright growth, would become crooked.

If these plants are to be purchased, the true globe sort is sold at eight or ten shillings a hundred, and sometimes a guinea, or more, after a hard winter.

When they are to be conveyed to any considerable distance, they should be packed dry, in small bundles of eight or ten, wrapping dry hay about them, and tying each bundle with a hay band, and pack the several bundles in hampers or large garden-mats; when they arrive, place the roots in water a few hours previous to planting.

Of manuring the Plants.

Such plantations of Artichokes which are permitted to remain several years in the same place ought to have the ground manured every other year, with some thoroughly rotten dung, applying it in November, at the time of landing up the plants, and dig it in one good spade deep.

By this practice a plantation of Artichokes will continue in good condition, and bear tolerable heads for several years; though as

they grow old, the heads will be smaller in proportion.

Second Species of Cynara, the Cardoon.

The Cardoon, in its general habit, greatly resembles the Artichoke plant, but is of larger and more regular growth; the leaves more upright, taller, broader, and more deep and regularly divided; and the stalks of the leaves, blanched, are the only eatable parts of the plant.

There is but one species, viz.

CYNARA *Cardunculus*.

Cardunculus or *Cardoon*.] Cynara, with thick, fleshy, fibrey roots, crowned by a considerable cluster of large, erect, deeply-pinnatifid leaves, four or five feet high, having all the lobes pinnatifid and thick prickly foot-stalks; and amidst them, upright tall stems, terminated by scaly, Artichoke like heads, furnishing flowers and seed. It is a hardy plant, and prospers in the open quarters of the kitchen-garden.

This plant is often biennial in England, arising from seed in spring, obtains perfection in autumn and winter, shoots up stems in spring after, flowers in July, ripens seed in September, and the whole often dies the winter following in this country; but it rarely produces good seed here, so it is commonly procured by the seedsmen from France, Spain, and Portugal. The plant is large, regular, and of noble appearance in its general growth.

The stalks of the leaves being thick, crisp, and palatable, are the eatable parts, first blanching them like celery about a yard or more long, to render them white, tender, and agreeably flavoured, which otherwise would be rank and bitter; they are in perfection in autumn and winter, and are used for fallads, soups, stewing, and other culinary purposes.

It is but of little estimation at present in England, nor is it much cultivated now by the market gardeners; it requiring so much room to grow, and there being but little demand for them, they often do not pay for the culture, though they sell for five shillings or three half crowns a bunch, and only three plants in each.

A few of them, however, for variety, merit a place in every considerable kitchen-garden, both for use and market.

The

The plants being of considerable growth, require to grow in rows five feet asunder, and four distant in the rows.

Propagation and Culture.

It is propagated by seed sowed annually in the full ground in March, either in a bed for transplantation, or at once in the place where you design the plants shall stand to come to perfection. Most authors direct the former method, though some of them, seemingly, neither saw nor practised any, nor perhaps ever saw the plants; we, however, have practised both ways, and have experienced, that hoeing in the seeds where the plants are to remain, is the most successful culture, and is the method I have also lately observed practised in some of the most eminent kitchen-gardens in the vicinity of London; for the plants being rather of rampant growth, and very flaggy on removal in dry or hot weather, they do not succeed so well by that method, as when they always remain in the same place, in which they grow faster, stronger, and sooner arrive at a proper state of growth for blanching.

But we shall exhibit the practical directions for both methods of culture.

First by transplantation.—Sow the seed in March, or beginning of April, by broad-cast, in a bed of rich earth, tread it in, and rake the ground, and when the plants are three inches high, thin them to four or five inches distance, that they may not draw each other weak; and in June they will be fit to transplant: in the beginning or middle of June, therefore, prepare an open space of ground that has been dunged in the preceding winter or spring; and there draw lines five feet distance, and put in the plants by dibble, at four feet distance in the lines, either on level ground, or hole them, in wide basin like holes, eighteen inches over, and six or eight deep, making the sides sloping, so loosening the bottom well, and set one good plant upright in each hole; give water directly, which repeat, if dry weather, every evening or morning till they have taken root; after this, all they require is hoeing the ground occasionally to kill weeds, until the end of September or October, when the plants will be arrived nearly at full growth, so as the leaves of the different plants will almost meet, and those of each plant are then to be tied together, and landed up to blanch them, as hereafter directed.

By sowing where they are to remain.—Let

the ground be marked out in lines five feet distance, as in the transplanting method, then along each line form basin-shaped holes, eighteen inches wide, and about three deep, the holes four feet from centre to centre; in each hole drill in three seeds, ranging the way of the row, covering them half an inch deep; give occasional waterings in very dry weather; and when the plants are come up three or four inches high, thin them to one of the strongest in each hole; at the same time clear away weeds, and stir the earth with a hoe about each remaining plant; and thus they will grow more freely and stronger than those which are transplanted, and sooner arrive to full size, with large stalks, in fine order for general blanching.

These plants are cultivated in wide rows, on account of their large growth, as well as for the convenience of having a sufficient portion of earth to land them to a due height, i. e. two or three feet at least; but in rich ground they often grow four feet high, and it is necessary to land them up, for blanching, almost their full length.

All the culture necessary for these plants during their growth till fit for blanching is, to keep them clean from weeds, by hoeing the ground.

As these plants stand at considerable distances from each other, you may have some small temporary crops between the rows the first three months, such as spinach, lettuce, endive, cabbage, savoy, or broccoli plants, for transplanting, &c. observing to keep the holes of Cardoons perfectly clear from every thing.

Method of landing them for blanching.

In the latter end of September, or in October, the Cardoons will be grown very large, and their foot-stalks have acquired a thick substance, you must then tie up the leaves of each plant, to admit of landing them up closely all around, for blanching, which will be six or eight weeks in effecting, and the plants will come in for use in November and December, and continue all winter.

But if the plants are required for use as soon as possible in autumn, the blanching may be begun in August, so as to have the plants for use towards the latter end of September and October; but by tying up, and landing the plants before they are full grown, they never acquire a due substance in the stalk, and the excellence of a Cardoon is, to have the

the stalks (the eatable part) broad and thick.

The method is, first, having hoed and cleared the ground from weeds, then, having procured some hay-bands an inch and a half thick, proceed with these materials, on a dry day, to tie up the leaves of each plant moderately close, and regularly together, winding the hay-band closely around the plant almost to its top; this done dig the earth, and as you proceed, bank it up close round each plant nearly as high as the tying or bandage, smoothing it with the back of the spade, both to fix it properly, and that it may readily shoot off the wet; observing, if the plants should advance more in height, to continue the tying of hay-bands higher in proportion; for it is necessary to have them tied up nearly their full height, both to blanch them more effectually, and secure them from injury of wet and frost.

To obtain a more regular succession, the landing may be performed only to about one third of the plants at a time, allowing the distance of a fortnight between each time of landing.

In six or seven weeks the plants are sometimes tolerably blanched, but in two months or ten weeks, they are generally in excellent order.

They may be continued all winter, with the care of covering the tops of the plants with long litter during hard frosts.

To save Cardoon seeds.—Cultivate a few plants in a sheltered sunny place; let them stand unblanched, protecting them from frost with light litter; they will shoot up in spring following, flower in July, and if a fine warm dry autumn, they will ripen seed towards Michaelmas.

CYNOGLOSSUM, Hound's Tongue.

It furnishes hardy herbaceous biennials, perennials, and annuals, for medical use, and as flowering plants for ornament in gardens.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is oblong, five-parted, and permanent. COROLLA is monopetalous, funnel-shaped, five-parted at the brim, and the chaps closed. STAMINA, five filaments, and roundish antheræ. PISTILLUM, four germen, permanent style, and indented stigma. PERICARPIUM none, but four ovilli, having four seeds.

The material species are,

¹CYNOGLOSSUM *Officinale*.

Officinal, or Common biennial Hound's Tongue]

Cynoglossum, with large, thick, blackish roots, crowned by large, oval, spear-shaped, hoary leaves, and amidst them, upright firm stalks two feet high, adorned with narrow close-fitting leaves, and terminated by reddish flowers, in June and July.

Varieties.] White flowering Hound's Tongue—Evergreen Hound's Tongue.

This species and varieties may be considered both as biennials and perennials, because in moist soils they often die soon after they have perfected seeds; but in dry gravelly soils, the roots are often of several years duration.

It grows wild under hedges, and is chiefly valued for its root in medicine.

²CYNOGLOSSUM *Omphalodes*.

Omphalodes, or perennial, creeping, Venus Navel Wort.] *Cynoglossum*, with slender trailing stalks, creeping and rooting at every joint, heart-shaped smooth leaves, on long foot stalks; and from the axillas of the stalks, bright blue flowers in loose panicles, appearing in March, April, and May.

³CYNOGLOSSUM *Linifolium*.

Flax leaved Annual Hound's Tongue, or Common Venus Navel-Wort.] *Cynoglossum*, with upright, slender, branchy stalks, six or eight inches high, garnished with long, very narrow, smooth, greyish leaves; and all the branches terminated by loose panicles of small white flowers, in June and July.

⁴CYNOGLOSSUM *Lusitanica*.

Portugal Annual Hound's Tongue, or Taller Venus Navel-Wort.] *Cynoglossum*, with upright branchy stalks ten or fifteen inches high, garnished with spear shaped rough leaves, and all the branches terminated by loose spikes of white flowers, in June and July.

The flowers of all these plants are singly, of one funnel-shaped petal, are small but pretty numerous, which in the first, third, and fourth sorts, are succeeded by plenty of seeds.

Of these four species, the second, third, and fourth sorts, are those that merit culture as flowering plants, and are pretty ornaments for the fronts of borders, &c. the two latter of which have been long inhabitants of our gardens, in the collection of hardy annuals.

They are all hardy, and prosper in the open borders.

Propagation.

The first species may be raised by sowing the seed in any soil in autumn or spring, and

and they will rise plentifully in March or April.

The second species propagates itself abundantly by its rooting stalks, cuttings of which may be taken off with roots, in spring, summer, or autumn, and planted where they are to remain.

The two annual sorts are always raised from seed in spring, sown in patches in the borders where they are to flower, sowing several seeds in each patch a quarter of an inch deep; and when the plants come up, occasional water and weeding is all they require, and by two or three different sowings, they will flower from June till the end of summer.

CYPRIPEDIUM, Ladies Slipper.

It consists of two species of hardy herbaceous perennials for ornament, growing erect about a foot high, garnished with large oval leaves, and crowned by large, quadripetalous, nectarious flowers.

Class and order, *Gynandria Diandria*.

Characters.] CALIX is a spathe. COROLLA, four or five long, spear-shaped, expanded, erect petals, and in the midst a large, swollen, roundish, hollow nectarium. STAMINA, two short gynandrous filaments, and erect antheræ. PISTILLUM, a long contorted germen, short style, and obsolete stigma. PERICARPIUM, an oval, trigonous, three-furrowed, unilocular capsule, and numerous seeds.

The species are,

¹CYPRIPEDIUM *Calceolus*.

Calceolus Maria, or Common Ladies Slipper.] Cyripedium, with thick, fleshy, fibrous, creeping roots, sending up, in spring, several upright robust stalks a foot high, adorned with large, oval, spear-shaped, ribbed, close-fitting leaves, placed alternate, and surmounted by a spathe, protruding a large flower, expanding its four petals cruciforme, having in the centre a large hollow nectarium; the whole very elegant, and of different colours in the varieties.

Varieties are] Common Ladies Slipper, with deep-purple flowers—Pale-purple flowers—Golden flowers—Red flowers—Large yellow flowers—With variable flowers.

This species and respective varieties are perennial in root, but the stalks and leaves rise annually in spring, and decay in autumn, and all the sorts flower in June; are extremely ornamental, and their structure singularly curious, particularly in their large roundish nectarium, which is feigned to re-

semble a slipper; hence the plants derived the name.

It grows wild in some shady woods in Britain, but it nevertheless highly merits culture in every eminent garden, both as a plant of curiosity and ornament.

²CYPRIPEDIUM *Bulbosum*.

Bulbous Ladies Slipper.] Cyripedium, with a roundish bulbous root, crowned by radical roundish leaves; and between them erect low stalks, terminated each by one large flower, having an oblong nectarium.

Both the species, &c. are perennial in root, but annual in stalk and leaves.

The flowers of all the sorts appear the end of May or in June, all of them composed of four or five large expanded petals, and a very conspicuous nectarium in the centre; succeeded by ripe seeds in August, and they soon after decay to the roots.

They are very hardy, and delight in a somewhat moist undunged soil, open only to the morning sun. They succeed either in the full ground or in pots.

Propagation, &c.

The first sort and varieties, having knotty, fibrey, creeping roots, may be propagated by dividing or taking off joints in autumn, as soon as the stalks decay.

The bulbous sort is also increased by the roots when the stalks decay.

Both the species may also be raised from seed, sown in autumn in a shady border, and the plants will flower the second or third year; especially if suffered to stand where they were sowed.

These plants should not be often removed, which would retard their flowering.

CYTISUS, Tree Trefoil.

This genera furnishes some elegant flowering shrubs and evergreens, of hardy growth, for the pleasure ground, adorned with oval leaves by threes, and long spikes of yellow papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX is bell-shaped, short, and divided into two lips, the upper one bifid, and the under one three-parted. COROLLA is papilionaceous; the standard oval, rising, and reflexed on the sides; the wings obtuse, and the length of the standard, and the keel bellied and acute. STAMINA, ten diadelphous filaments, and simple antheræ. PISTILLUM, an oblong germen, simple style, and obtuse stigma. PERICARPIUM, an oblong,

oblong blunt pod, narrow at the base, and kidney-shaped seeds.

There are about five species of *Cytisus* in the English gardens, three of them deciduous shrubs, and one or two evergreens.

The species of our gardens are,

¹*CYTISUS Laburnum*.

The Laburnum, or Large Deciduous Cytisus.] *Cytisus*, with a large upright tree-stem, branching into a full-spreading head, twenty or thirty feet high, having smooth greenish branches, oblong-oval entire leaves, by threes, on long slender foot-stalks; and from the sides of all the branches, numerous yellow flowers collected in long spikes, hanging loosely downward, appearing in May.

Varieties of this are] Common broad-leaved Laburnum—Narrow-leaved, long spiked Laburnum, having very long pendulous spikes of flowers—Short-spiked Laburnum, having short, roundish, thick spikes of flowers—Variegated-leaved Laburnum. The first two of which varieties are tolerably permanent from seed, but the other two must be continued by cuttings.

All these varieties are deciduous, but their leaves appear early in summer, which, together with their numerous, long, pendant spikes hanging from every part of the branches, appear very ornamental, and are well adapted to place on the borders of woods, wildernesses, and large shrubbery plantations, on the boundaries of lawns, parks, &c.—And, although they are generally considered only as ornamental shrubs, if encouraged by training them to a stem at first, and suffered to stand, they will form moderate-size timber-trees: they grow naturally on the Alps, the mountains of Dauphiné, and in the Highlands of Scotland; and the timber being very hard, and taking a fine polish, is frequently used for making chairs, tables, bedsteads, and other furniture, which are said to equal the finest mahogany in beauty.

The trees are so very hardy, that they will prosper any where, and are of very quick growth.

²*UYTISUS Sessilifolius*.

Sessil-leaved Deciduous Cytisus, often called Cytisus Secundus Clusii.] *Cytisus*, with a low shrubby stem, branching into numerous, erect, brownish branches, forming a bushy head five or six feet high, garnished with small oval leaves by threes, some on very short foot-stalks, others sitting close, and bright yellow flowers in short erect spikes at

the ends of the branches, appearing in June.

³*CYTISUS Nigricans*.

Black Cytisus.] *Cytisus*, with a short shrubby stem, dividing low into many erect slender branches, forming a bushy head four or five feet high, oblong-oval, dark-green, trifoliate leaves, and yellow flowers, terminating all the branches in upright spikes, appearing in July.

⁴*CYTISUS Hirsutus*.

Hairy Evergreen Neapolitan Cytisus.] *Cytisus*, with an upright, shrubby, grey stem, sending out many erect, greenish, hairy branches, forming a fine head six or eight feet high, closely garnished with small, oval, hairy folioles by threes, on short foot-stalks, and yellow flowers from the sides of the branches in short pendulous spikes, having trifid hairy cups, appearing in June.

This species being rather impatient of very severe frost, should have a dry soil, and sheltered situation in the shrubbery.

⁵*CYTISUS Austriacus*.

Austrian, or Tartarian Evergreen Cytisus.] *Cytisus*, with a shrubby stem, dividing low into many greenish branches, forming a bushy head three or four feet high, closely garnished with oblong-oval, smooth, whitish-green leaves, and bright yellow flowers, in close umbellate heads at the ends of the branches, having a cluster of leaves under each head; appearing in May.

Variety.] Austrian, — Siberian *Cytisus*, with smaller leaves, naked flower-stalks, and smaller flowers.

These five species have universally trifoliate leaves, i. e. three folioles on each foot-stalk.

The flowers of all the sorts are papilionaceous, or butterfly-shaped, consisting of the standard, two wings, and the keel; all of them flower abundantly in this country, and are succeeded by oblong pods, containing plenty of ripe seed in autumn.

All these shrubs have great merit in ornamental plantations, either to assist in forming clumps or continued shrubberies; their numerous trifoliate leaves being finely adapted for effecting variety in assemblage, and during their bloom, they appear covered with flowers.

The large sorts, such as the several varieties of *Laburnum*, should be stationed rather backward in clumps, and other shrubbery works; and the other four species should occupy

cupy places more towards the front, and in the most conspicuous departments.

They should all be suffered to retain their natural growth, except only cutting off any very irregular shoot or branch.

All the sorts are hardy, and will prosper in any common soil and exposure; though, as the *Cytisus Hirsutus* is sometimes affected by severe frost, it should have a dry soil, and somewhat sheltered situation.

Propagation.

All the sorts are raised plentifully by seed, and some sorts by cuttings.

By seed.—The seed grows freely in the full ground, and should be sown in March, in four-foot beds, either drilling it in, half an inch deep, or sow it on the surface, and cover it that depth with earth; they will come up in six or seven weeks; keep them weeded during summer, and in winter it may not

be amiss to protect the *Cytisus Nigricans* and *Cytisus Hirsutus*, by occasional shelter of mats, during severe frost; and in spring following, the seedlings in general, if they stand very close, may be transplanted into the nursery, in rows two feet distance, the Laburnums and the others a foot; allowing them more room as they advance in growth; and here they may remain two, three, or four years, till large enough for the shrubbery.

By cuttings.—Most of the deciduous sorts will also succeed this way, and October and November is the best time for planting them. Chuse young shoots eight, ten, or twelve inches long, plant them in rows a foot apart, and five or six inches in the lines; and they will be rooted in one year.

All the culture these plants require in the nursery, is to keep them clear from weeds, and to dig the ground annually between the rows.

D.

DAPHNE, Spurge Laurel, and Mezereon.

This genus consists of low ornamental shrubs, of the evergreen and deciduous tribe, adorned with spear-shaped leaves, and small, but numerous, monopetalous, four-parted flowers.

Class and order, *Ostendria Monogynia*.

Characters.] **CALIX**, none. **COROLLA** is monopetalous, funnel-shaped, and divided into four oval spreading segments. **STAMINA**, eight short filaments inserted into the tube, and erect bilocular antheræ. **PISTILLUM**, an oval germen, short style, and a capitated depressed stigma. **PERICARPIUM**, a roundish unilocular berry and one seed.

There are seven or eight species, but not more than two common to the English gardens, and which are the most beautiful and the only sorts that demand particular attention in horticulture.

The first is an evergreen, and the second is deciduous, viz.

¹**DAPHNE Laureola**.

Laureole, or Spurge Laurel.] **Daphne**, with

many greyish-coloured stalks from the root, branching irregularly three or four feet high, closely garnished with thick, spear-shaped, smooth, shining, evergreen leaves, sitting close to the branches; and from the upper parts, numerous, small, yellowish-green flowers in clusters, succeeded by oval berries, ripening to a black colour; flowers in January and February, and the seeds ripen in June.

Variety.] Variegated-leaved Laureola.

²**DAPHNE Mezereon**.

The Mezereon.] **Daphne**, with a short, strong, woody stem, branching out low into many erect branches, forming a regular bushy head, four or five feet high, garnished with small, spear-shaped, deciduous leaves about two inches long, and the upper parts of all the branches and young shoots closely adorned with numerous flowers, by threes, coming out early before the leaves, of different colours in the varieties, and succeeded by many roundish berries, in some yellow, others red.

Varieties.

Varieties.] Mezereon with white flowers and yellow berries—Purple flowers and red berries—Pale-red flowers and red berries—Crimson flowers and red berries—With variegated leaves, striped with yellow.

The flowers of both these species and respective varieties consist each of one four-parted petal, very small, but numerous, and those of the Mezereon are the most conspicuous and beautiful; all the sorts flower early, and are succeeded by many berries, each furnishing one seed; ripe in June and July.

Both the species are very hardy, and prosper in any situation and soil of a garden.

The first species, *Daphne Laureola*, is an inhabitant of our woods, and being a hardy and delightful little evergreen is peculiarly adapted for wilderness and wood-works in gardens, as it will flourish under larger shrubs and the drip of trees; is also proper for any other shrubbery departments, no weather hurts it, and remains always green.

The *Mezereon* and varieties are all deciduous, but flower remarkably beautiful in February and March before the appearance of leaves, every shoot being covered with flowers, are extremely ornamental at that early season, as well as very diffuse in a most agreeable fragrance; and when they fade, the leaves advance, and the berries continue their growth, ripening in June and July; which have also a pretty effect in forming variety, but are generally soon devoured by the birds.

The several varieties are proper ornamental furniture for gardens of any extent, and should occupy the most conspicuous parts of shrubbery-works contiguous to lawns, principal walks, and places near the habitation.

Every part of those shrubs are of a remarkably hot quality, particularly the root, which is used in medicine; for which purpose some gardeners near London, cultivate many of the *Mezereons* to stand several years to acquire large roots, then dig them up occasionally, cut off the root, and sell them for three or four shillings per pound to the druggists and physic-herb-shops.

Propagation.

Both species are raised with facility from seeds, i. e. the berries which the shrubs furnish in great plenty, if secured from birds, by netting them, as soon as they begin to ripen.

The seeds grow freely in the common ground, and the best time for sowing them is in

autumn, soon after they are ripe; and there will be a chance of their coming up the spring following, otherwise, when not sowed till spring, they often remain a whole year before they germinate. Having procured the berries, dig a bed of light earth, and rake it fine; then, either draw an inch of earth off the surface, and sow the seed, and cover them over with earth, or draw flat drills that depth and six inches distance, sow the berries therein, earth them over as above, and smooth the surface.

The plants will appear in April or May; keep them weeded all summer, and in autumn or spring following, if they should stand very close in the seed-bed, the largest may be transplanted; otherwise they may remain until the second autumn till October, then plant out the whole in the nursery, in rows eighteen inches distance, to remain till two or three feet high, and are then fit for the shrubbery.

DATURA, Thorn-Apple, formerly *Stramonium*.

This genus furnishes some herbaceous, large, erect, flowery annuals for the pleasure-ground, rising three or four feet high, branchy, and adorned with very large, oval, and heart-shaped leaves, and considerable funnel-shaped flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is monophyllous, oblong, tubular, ventricose, five angled, and indented in five parts. **COROLLA** is monopetalous, funnel shaped, having a long cylindrical tube, a pentangular spreading limb, rising at the angles into acute points. **STAMINA**, five awl-shaped filaments, and oblong compressed antheræ. **PISTILLUM**, an oval germen, erect style, and thick obtuse stigma. **PERICARPIUM**, an oval, bilocular, quadri-valvular capsule, and numerous kidney-shaped seeds.

There are about four species in the British gardens, all of them annual, and of erect strong growth, rising each with a single luxuriant stem, dividing into many spreading branches.

The species are,

DATURA Stramonium.

Stramonium, or Common Thorn-Apple.] **Datura**, with an erect, strong, round, hollow, green stalk, branching luxuriantly a yard high, having the branches widely extended on every side; large, oval, irregularly-angulated, smooth, dark-green leaves; and from the

the divisions of the branches large white flowers singly, succeeded by large, oval, prickly capsules, growing erect, commonly called Thorn-Apples.

This is often found wild upon dunghills, but is often cultivated in gardens for variety; where, if the seeds are suffered to scatter, numbers of young plants will rise naturally for several years after.

²*Datura Tatula.*

Tatula, or Great Purple Stramonium.] *Datura*, with an erect, large, purple stalk, branching four or five feet high, and widely on every side, large, heart-shaped, angulated, indented, smooth leaves; and, from the axillas of the branches, long purple flowers singly, succeeded by oval, spinous, erect capsules.

Variety.] With white flowers.

³*Datura Metel.*

Metella Nut, or White African Thorn-Apple.] *Datura*, with an erect large stalk, branching two or three feet high, large heart-shaped, almost entire, downy leaves, and, from the axillas of the branches, long, widely-expanded, pure white flowers singly, succeeded by spinous drooping capsules.

Variety.] With double flowers.

⁴*Datura Fastuosa.*

Egyptian Purple Thorn-Apple.] *Datura*, with an erect, purple, shining, smooth stalk, branching three or four feet high, large, sinuated, smooth leaves, and, from the axillas of the branches, large widely-expanded flowers, purple without, and pure white within, succeeded by globular drooping capsules, set with many blunt tubercles.

Varieties.] *Egyptian Thorn-Apple* with single flowers—semi-double flowers—and with double flowers.

The flowers of all these annuals are universally of one large funnel-shaped petal, having a long tube and spreading pentagonal limb, succeeded by large roundish capsules the size of middling apples, which being closely set with sharp spines, derived the name Thorn-Apple.

They all flower in June, July, and August, and are succeeded by capsules in autumn, furnishing abundance of seeds.

The first and second species are hardy, and easily raised in the natural ground.

But the third and fourth sorts are tender, and require to be raised in a hot-bed, and from which, either transplanted into pots, or in the borders of the pleasure-ground,

The species in general are considered as plants of ornament, though the first sort often becomes a troublesome annual weed; but this and the second merit a place in large borders for variety; and the third and fourth species, and respective varieties, being extremely beautiful in their flowers, demand admittance in the collection of curious annuals. See ANNUAL PLANTS.

Propagation, &c.

The hardy sorts may be sown in autumn or spring, in the borders and other compartments of the pleasure-ground where you design they shall flower; sowing them in patches four or five seeds in each, half an inch deep; and when the plants come up, thin them to one of the strongest in each patch.

But the third and fourth sorts must be sown in March, in a hot-bed, under frames and glasses, in common with other tender annuals, such as balsamines, egg-plants, marvel of Peru, &c. See ANNUAL PLANTS. When they come up, admit air daily by tilting the lights; and in April, when the plants are two or three inches high, prick some singly in pots, and plunge them also in a hot-bed, as directed for amaranthus, cock's comb, &c. to forward them, and draw them up tall; others may be pricked in the earth of the hot-bed, six inches distance; and in June, the whole should be moved into the open air, placing those in pots to adorn fore-cours, and the rest may be taken up with balls, and planted in the compartments of the pleasure-garden.

DAUCUS, the Carrot.

This genus furnishes several herbaceous species, but of which only one claims esteem for general gardening, which is a biennial esculent, most valuable for its large eatable root, and which is the *Daucus Carota*, or Common Carrot; the others having but little merit, either for use or ornament, are rarely cultivated.

Class and order, *Pentandria Digynia.*

Characters.] *CALIX*, an umbellate flower, composed of many smaller umbels, the general umbel having a many-leaved involucre, which for the partial umbels is more simple and short. *COROLLA*, a radiated, difform, general umbel, having numerous florets, each composed of five, heart-shaped, inflexed petals. *STAMINA*, five filaments, and simple antheræ. *PISTILLUM*, a small germen under each floret, two reflexed styles, and

and obtuse stigma. PERICARPIUM, none. SEMEN, a small, two-parted, hairy fruit, each having two seeds.

The species denominated Carrot is,

DAUCUS *Carota*.

Carota, or Carrot.] Daucus, with a large, long, taper, perpendicular root, fifteen or eighteen inches long, crowned by many long, erect, finely-divided leaves, and when it shoots for seed, an upright stalk, branching out three or four feet high, having all the branches terminated by large white umbels, in May and June, succeeded by hairy seeds in August.

Of this species there are several varieties, in respect to the colour of the root, though there is only one sort in general esteem.

Varieties are] *Carota* with an orange-coloured root, commonly called *Orange Carrot*—With a red root—With a purple root—With a yellow root—With a white root—all of them wholesome for eating.

They are all biennial, rising from seed one year, and obtain perfection; and the next they shoot up into stalk, produce flowers and seed, and the root soon after dies.

Of these varieties, the first sort, *Orange Carrot*, is that which is most proper for general culture; it grows longer, larger, and commonly of more handsome growth than the others; as, when cultivated in a light, loose, deep soil, they often grow fifteen or eighteen inches long in the eatable part; and from two to three or four inches diameter at top, diminishing gradually in size to the lower end; but as one method of culture suits the whole, a few of the others may also be raised by those who are fond of variety, as they are all easily raised in any quantity from seed annually, sown at almost any time of the year, though the spring is the proper period for sowing the general crops.

The principal season of Carrots is from June until Christmas; but by different sowings, as hereafter mentioned, they may easily be obtained throughout the year.

Propagation and Seasons for sowing.

All the varieties are propagated by seed annually in spring; or, to obtain a greater succession, may be sowed at three or four different times of the year; observing, however, that the principal sowing season is, from about the middle of February to the latter end of March, being the only proper period for sowing the main or general crop, which will

furnish a supply of Carrots from June till March following.

However, when young Carrots are required as early as possible, and a succession of such to be continued during summer and autumn, &c. four different sowings should be performed in the following order:

The first or early sowing to be about Christmas, or in the beginning, middle, or any time of January, in mild dry weather, on a warm rich border, or in any rich, dry, sheltered situation; they will come in for use early in May.—But as these early crops are not always so successful as those of the February or March sowings, no considerable space of ground should be sowed, only a little to come in a few weeks before the general crop.

The second sowing, or main crop, may be performed towards the latter end of February, or first or second week in March, but not later than the end of that month; though sowings in April or May will succeed, but then the Carrots will scarcely acquire half the size of those sown in February and March; therefore mark this for the main crop, as from which sowings we may obtain good Carrots from June till March following, that is, it will furnish fine young Carrots in June and July, but will be of a handsome large size in August, and by the end of September or October, they will be arrived to full perfection, which in November should be taken out of the ground, and preserved in sand for winter and spring use, because, if left longer in the ground after being arrived at full growth, they would canker, and rot away in winter.

The third sowing, effected about the middle of July, will furnish a supply of young Carrots in the latter end of September, October, November, &c.

And, a fourth sowing is performed about the middle or latter end of August, to stand the winter for an early spring crop; for the plants coming up in September, continue a slow growth all winter, till retarded by frost; and then, if sheltered in very severe frosts by a light covering of dry long litter, just to preserve their tops or leaves entire, will be of much advantage, and you will obtain young Carrots in March and April, or till those of the early spring-sowing come in: these autumn sown Carrots, however, are apt to be tough and sticky, but as they come at an early season, when young Carrots are a rarity, they are, therefore, nevertheless always acceptable both for

for family-use and in market, and with which the London gardeners supply the markets plentifully from March until May, or till the arrival of the early spring-sown crops.

Early Carrots may also be obtained by aid of artificial heat. See their *Culture in Hot-beds*.

Of the proper Soil for them, and its Preparation.

The soil most proper for Carrots is that which is light, loose, and of some considerable depth; and if inclinable to a sandy nature, in a moderate degree, it will be an advantage; it is therefore necessary always to chuse a spot of the lightest and deepest soil in the garden, and such as hath been heretofore enriched with proper manure, observing, if it has been dunged the preceding year, it is more eligible than dunging it the same season, as fresh dunged land is apt to promote worm-eaten, or a sort of canker in the roots of the Carrots; but where the ground is so poor, that you conceive dunging is necessary, use that which is thoroughly rotted, and spread it evenly over the surface of the ground, to be trenched in regularly.

As to situation, an open exposure free to the sun and air, as distant from spreading trees as possible, should be chosen, especially for the main crops, which should always be in the large open quarters.

The necessary space of ground to sow for family service is, for the main crops, from about two or three to fifteen or twenty rod, according to the size of the family.

The ground should be trenched one full spade deep at least; but, where the depth of proper staple will admit, it is advisable to trench it two moderate spades depth; for as Carrots often strike two feet perpendicularly into the ground, they consequently require a considerable depth of loose soil, whereby the swelling part of the root will be long, straight, and of large size; observing likewise, that it is advisable for the ground to be trenched up in rough ridges in winter some months before the sowing season, that it may be well meliorated by the weather, which will be of singular advantage, and is particularly necessary for the early and general crops; and at sowing time, it is soon levelled down for the reception of the seed: it is also of much importance in trenching the ground to take but thin spits, and break all large clods, so as the parts may be well separated or divided, that

the roots may have full liberty to perform their perpendicular growth; for when obstructed in that by the too compactness or lumpiness of the earth, they grow short, branch or divide into forks, and become very irregular.

Having therefore ridged the ground, as above, in winter, then, at the sowing-season, take advantage of dry fine weather to level it down for sowing, stir every part, and preserve a level surface; and, as soon as the ground is thus prepared, if the surface is not wet, but will readily rake without clogging, directly sow the seed, at least the same day, while the earth is fresh stirred, and before rain falls to wet the surface and render it cloggy, or is too much dried by the sun and wind; and the following is the method of sowing.

Method of sowing the Seed.

Always, if possible, procure new seed of the former year's sowing, for that which is more than one year old never grows freely; the necessary quantity is, at the rate of about a pound and a half to an acre; so that for the largest family garden, a quarter of a pound is sufficient, and is seldom more than a shilling or eighteen pence per pound.

It must be sowed by broad-cast, or scattered as equally as possible all over the surface of the ground, and raked in.

A calm dry day must be chosen for sowing this seed, otherwise being of very light substance, the wind would blow it away; but previous to sowing it, as besides its being of the above light nature, it adheres closely together by its rough hairy borders, it is proper to mix therewith some sand or fine dry mold, rubbing the whole between the hands, both to separate the seeds, and cause the sand to adhere a little, to render them more weighty; by this means you will be able to sow it regularly, which otherwise would be apt to fall in heaps; then having prepared the ground, as before directed, sow the seed on the surface, moderately thin, and directly rake it in; or the ground may previously be formed into five feet wide beds, having spade-wide alleys between, which may be necessary in moist or heavy soils, or when it is designed to thin out the Carrots by degrees for use, so may stand in the alleys to sow, and rake in the seed, also to thin out the young Carrots occasionally, without treading on the beds to bind the earth too close. But where the

ground is light, loose, and dry, the seed may be sown all over the piece; then tread the ground over evenly with the feet almost close together, taking short steps, being necessary both to bury the seed more equally, and settle the ground evenly in every part, that when you stand to rake it, the feet will not sink in holes, in which the seed would be unavoidably drawn in raking; therefore, as soon as the seed is sown, and trodden in as above, rake the ground over evenly with a large wide-teethed rake, either a wooden or iron one; raking once in a place is sufficient, and as you go on trim off all large stones, and the work is done.

The seed being thus sown, it, if good, will soon germinate, and the plants will appear in fifteen or twenty days, and sometimes in a little less, or longer time, according to the season of sowing, nature of the soil, and temperature of the weather. When they are two or three inches high, they must be thinned to several inches distance, and cleared from weeds, agreeable to the following directions.

Culture of the Plants.

When the young plants are come up about two or three inches high, they should be thinned to about six, eight, or ten inches distance, according to the size you intend they shall grow, and at the same time must be well cleared from weeds.

This work may either be performed by hoe or hand; but hoeing is not only more expeditious, as by loosening the surface of the earth about the young plants, it will prove a very essential service in promoting their progress of growth. A small hoe two or three inches wide should be used; and dry weather should be chosen for performing the work, that the superabundant plants and weeds, as they are hoed down may die, for if done in moist weather, many would strike root as they lie, and grow again. In the course of the work, be careful to thin the plants regularly to five or six inches distance at least, which may be sufficient, if the Carrots are designed to be used while young, and thinned out by degrees for use; but if intended to have them stand to grow to full size, hoe them at once to eight or ten inches distance, singling out the most promising to stand, and leave no where two or more together; observing to cut up all weeds, and stir every part of the ground between all the standing plants.

In a fortnight, or three or four weeks after, as you shall see occasion, run over them again with a hoe, to cut up any straggling superfluous plants that escaped you in the first hoeing, cutting up also all weeds, and the plants will soon after cover the ground, and require no farther culture.

In a month, or five or six weeks after the first hoeing, you may expect young Carrots fit to draw, which, if much wanted, may begin drawing when they are the size of your little finger; beginning with those which were left close on purpose for thinning, and thin them out for the table as they are wanted, in a regular manner, so as the remainder may have room to arrive at full growth.

But when it is designed to begin drawing Carrots for table when quite young, it is advisable, exclusive of the main crop, to sow a piece purposely for drawing; and when fit to hoe, thin them only four or five inches distance, and in May or June, when of due size for the table, by a gradual thinning out the largest for use, the others will gain more and more room daily; and thus a piece of Carrots may be continued in occasional drawing till the main crop is arrived nearly at full growth in August and September, and which may be taken up clear as they come to hand.

Therefore, to have the principal crop of Carrots as fine as possible, they, when fit for hoeing, should be hoed to the full distance at first, of eight or ten inches, as before observed, and suffer them to stand until August or September, before you begin drawing, when they will be long, large, and of handsome growth, and in October or beginning of November will be done growing, and should be then taken up and laid in sand for winter, as hereafter directed; which, where there is convenience to lay them, is the only method by which Carrots can be preserved in due excellence during that season.

Carrots designed for market should, during summer and autumn, whilst they remain in the ground and have leaves, be washed, bound in bunches by their said leaves, spreading the roots or Carrots themselves fan-fashion, twelve or eighteen, according to their size, in each bunch, which in the London markets sell from about eighteen pence to three or four shillings per dozen of bunches, according to the early or late period of the year, and size of the Carrots.

But

But in winter, as being devoid of tops, they are commonly brought loose in maunds or other large baskets, and sold by the basket, or, if large, by the score of roots.

Preserving them in Sand during Winter.

To preserve Carrots in good perfection through the winter, the full-grown crops should be taken out of the ground in November, when they have done growing, and the leaves begin to turn yellow and decay; and lay them in sand in a dry place out of the wet, and the reach of frost.

This is necessary for these reasons, first, that if permitted to remain in the ground in winter, they would be attacked by vermin, and become cankered and rotten, and in moist fat soils will often waste away to nothing: likewise, if they remained in the ground in winter, hard frosts prevent you digging them up when wanted; but by taking the roots out of the ground in autumn, they may be preserved perfectly sound till March or April following, and will be ready for use in all weathers.

They should be taken up in dry weather, with a three-tined fork, and spread regularly on the ground for a few hours to dry; then cut their leaves off close, and clear off all adhering earth, and carry them into a dry shed or other room, where they may be sheltered from wet and frost; there lay them in dry sand, first laying some sand, then a layer of Carrots, then more sand, and so proceed alternately, several layers one upon another, and as wide and long as convenient, in proportion to the quantity of roots to be thus preserved; covering the whole half a foot thick with straw.

By the above practice Carrots may be preserved in fine condition till April, both for family use and market.

Vast quantities of Carrots, preserved as above, are brought to London every winter from Sandwich in Kent; the grounds adjacent being of a sandy nature, is famous for producing the largest Carrots in England, some of which I have seen of a prodigious bulk; they are generally brought up by water, and deposited in the warehouses in Thames-street and Tooley-street, and places adjacent near London bridge, and there sold by the bushel, the price commonly a shilling or eighteen pence.

It is worth while to purchase some of these for seeds.

Raising them early in Hot-beds.

Young Carrots may be obtained at an early season by aid of hot-beds; therefore if you omitted an autumnal sowing in the full ground, for early spring service, or that those are damaged in winter, recourse may be had in January or early in February to a sowing on a hot-bed, either under frames or occasional shelter of mats.

Make the hot bed of hot dung, four feet wide, as long as convenient, and two feet high, and directly frame it, and put on the mold eight or ten inches deep, or for want of frames, may arch it with hoops to be covered with mats, first earthing the bed the above depth with light rich mold, and fix boards or a wreath of large straw-bands round upon the edge of the bed on the top of the dung to keep up the outside earth, or it might be banked up closely on each side and end with moist soil, as practised for asparagus hot-beds: then having levelled and smoothed the earth for the reception of the seed, sow it evenly on the surface, and beat it lightly down with the back of the spade, and then sift some fine mold over it a quarter of an inch thick: this done, arch the bed over with hoops, and every night and all severe weather cover it with mats, or, if you use a frame and glasses, the plants must be allowed the full air every mild day, by shoving off the lights; for the plants must not be kept close, otherwise they would draw up weak and never swell at root, so must only be covered principally on nights, and very severe or cold cutting weather.

When the plants are come up, and have two or three leaves an inch high, thin them by hand to three inches distance, which will be room enough, as they will be mostly drawn off for use while quite young.

They may be greatly forwarded in growth, by lining the bed on each side with hot dung, in a fortnight or three weeks after it is first made, and so repeat it once or twice more, according as the heat declines.

By this practice of raising Carrots in hot-beds, a few may be obtained for variety, a month at least sooner than any in the natural ground.

Raising them in Fields.

Field culture of Carrots is sometimes practised for feeding cattle, and sometimes in large quantities for the supply of markets, and

either of which differs but little in culture from that in gardens, only the ground is generally prepared by ploughing and harrowing, instead of digging and raking, and the proper time for sowing is March.

The ground should be naturally light, loose, of tolerable depth, and in good heart, as observed in the garden culture, and such that have been in tillage before; and if it has been dunged the preceding year, it will be a particular advantage; otherwise if the land is poor, some thoroughly rotten dung may be spread over the surface, and ploughed in. The ground should be ploughed fifteen or eighteen inches deep, if the depth of good staple will admit, which is effected by double ploughing, i. e. ploughing twice in the same furrow; and two different ploughings at least is necessary, but if three, it will be much the better, that is, the first should be in the beginning of winter, turning it up in high ridges; the second is proper in January or beginning of February, across ways the first; and the third and final ploughing should be in March, and should then be well harrowed to break the clods, and smooth the surface for the reception of the seed: this is to be sown in the broad-cast way, allowing a pound and half to an acre, mixing some sand or dry mold with the seeds, to enable you to scatter them more regularly, as in the garden culture. As soon as they are sown, harrow them in with a light harrow, and afterwards, when the surface is dry, roll the ground with a wooden horse roller to smooth the surface, whereby the seed will be more effectually covered, and the plants will rise more evenly.

When the Carrots are come up about three inches high, they must be hoed in dry weather, to thin them and destroy weeds; having a five or six-inch hoe, cut out the plants to eight or ten inches distance, stirring all the ground, and cut up all weeds; and in three or four weeks after, if weeds make their appearance, run over them again with the hoe, and they will require no further culture.

They will be grown to a large size in August and September, and be then fit for use; but if they are designed chiefly for winter eating, they should stand till November, then dug up, and laid in sand, to preserve them, as directed for the garden crops.

Saving the Seed.

To save Carrot seed, you may either leave some of the main crop in the ground in au-

tumn, at a foot distance, for that purpose; or, in spring, plant out a quantity of the finest of those which were taken up in autumn, and preserved all winter in sand.

But those which have been taken up and preserved in sand are preferable, especially for one thing; the roots being out of the ground, you can readily see and judge of their goodness, so as to select only some of the hand-somest for planting, making choice of such whose tops are not cut too close to spoil the shoot for the flower-stalk; they should be planted in February, in rows two feet distance and one foot apart in the lines, planting them perpendicularly and wholly into the ground about half an inch over their crown; they will readily take root, and shoot up flower-stalks, and require no other culture than hoeing occasionally to destroy weeds.

They will shoot up into stalk in April and May, be in full flower in June, and ripen seeds in August, which should then be cut in dry weather, and spread in the sun and air a few days till thoroughly dry, then thresh it out, and put it up in bags.

This seed will sometimes retain its growing property two or three years; however, never depend on any but one year old seed for any principal crop, nor should the seedsmen serve their customers with any that is older, as I am sure it would prove a great disappointment.

DELPHINIUM, Dolphin-flower, commonly called Larkspur.

The plants are hardy, herbaceous, flowery annuals and perennials, of upright growth, from about a foot and a half to four feet high, garnished with finely-divided leaves, and terminated by long spikes of pentapetalous flowers.

Class and order, *Polyandria Trigynia*.

Characters.] **CALIX**, none. **COROLLA**, five irregular petals, the upper one extended at the base into a tubular obtuse tail, and a bifid nectarium in the centre. **STAMINA**, many filaments, and small erect antheræ. **PISTILLUM**, three oval germina, three styles, and reflexed stigmas. **PERICARPIUM**, three united unilocular capsules, and many angular seeds.

There are about four species of *Delphinium* common to the English gardens, all of them considered as flowery plants, two of which are annual, and the rest perennial, viz.

DELPHINIUM Ajacis.

Ajacis, or Unbranched Annual Larkspur.] *Delphinium*, with an upright, simple, unbranching stalk, two or three feet high, garnished

nished with finely-divided leaves, and terminated by an erect long spike of flowers, having monophyllous nectariums, and of different colours in the varieties.

Varieties are] Unbranched Annual Larkspur, with single and double blue flowers—Single and double purple flowers—Single and double red flowers—Single and double white flowers—Single and double silver-coloured flowers—Single and double violet-coloured flowers—Single and double ash-coloured flowers—Single and double striped flowers.

All these varieties of *Delphinium Ajacis*, or Unbranched Larkspur, rise with a simple stem, scarce emitting any side branches; and each stalk is terminated by a very long, erect, flowery spike, composed of numerous closely-placed flowers, which exhibit a very ornamental appearance in June, July, and August, succeeded by plenty of ripe seed in September.

²*DELPHINIUM Ambiguum.*

Branched Annual Larkspur.] *Delphinium*, with an upright very branchy stalk three feet high, long finely-divided leaves, and all the branches terminated by long ascending spikes of flowers, having monophyllous nectariums, and of different colours in the varieties.

Varieties.] Nearly the same in colour as the Unbranched Larkspur, and of which are singles and doubles.

All the varieties of this species send out many branches horizontally, which turn upward toward the extremity, the flowers large, but rather thinly placed in the spikes; they all, however, form a very ornamental variety in the borders, &c. in July and August, succeeded by plenty of seeds in autumn.

³*DELPHINIUM Elatum.*

Tall Perennial Bee Larkspur.] *Delphinium*, with several upright stalks four or five feet high, adorned with hairy leaves, cut into many broad expanded segments, and all the stalks terminated by long erect spikes of blue flowers, having diphyllous nectariums, with bifid lips, bearded at the top.

⁴*DELPHINIUM Grandiflorum.*

Dwarf, Grandiflorous, Perennial, Bee Larkspur.] *Delphinium*, with upright branchy stalks a foot and a half high, smooth leaves, composed of many narrow segments, ending in several points, and towards the upper part of the stalks large azure-coloured flowers singly, having diphyllous nectariums, with entire lips, appearing in July, succeeded by seed in autumn.

Of these four species the two first and varieties are universally annual, but the third and fourth are perennial in root and annual in stalk, which rise in spring, and decay in autumn.

The names Larkspur and Bee Larkspur are derived from the resemblance of the tail of the corolla to the spur of a lark's foot; and from the nectarium of the perennial sorts to a bee.

The flowers of all the sorts are composed of five unequal petals, one at top, two sideways, and two at bottom, and a central nectarium; they are moderately large, numerous, and mostly collected into erect spikes, and are very conspicuous and ornamental.

All the sorts are very ornamental furniture for the borders and other compartments of the pleasure-ground, and are so hardy that they prosper in any common soil and exposure, and all the sorts are raised abundantly from seed in the full ground, as directed below.

Propagation and Culture.

The two annual sorts and varieties are raised from seed sowed annually in autumn, i. e. September or October, or early in spring, in patches in the places where the plants are to flower, for they do not succeed by transplantation; observing, that those of the autumn sowing grow stronger, flower earlier, and the flowers are generally larger and more durable than the spring-sown plants. It is also however proper to sow some in spring, in February or March, to continue a longer succession of bloom. The method of sowing them is, dig with a trowel small patches about nine inches diameter in different parts of the borders, towards the middle, or also in the fronts of the shrubbery clumps, and in each such patch sow eight, ten, or twelve seeds a quarter of an inch deep; and when the plants are an inch or two high, thin those of the unbranched sorts to about six or eight in each patch, and of the branched kinds, to three or four in each place, which is all the culture they require, and in which order of cultivation they will make a fine appearance.

But when intended to have a grand shew of them in beds by themselves, they are commonly sowed in drills, forming the drills lengthways the beds a foot asunder, and half an inch deep, so scatter the seeds thinly along the drills, and rake the earth over them evenly; but the unbranched kinds are the best adapted for this mode of culture.

Or they may be sowed broadcast on the surface of the bed, and raked in, and when the

the plants are an inch or two high, thin them by hand or hoe, to three or four inches distance, but the branched kinds to treble that distance.

To preserve the varieties of these two annual species from degeneration, all those of bad colours, and that are very single, should be pulled out as soon as they shew bloom enough to discover their properties; for their farina would impregnate the fine sorts, and cause a degeneracy.

The perennial sorts.—These are also raised plentifully from seeds sown in autumn or spring, in a bed or border of common earth for transplantation. Sow them on the surface, and rake them in, and when the plants come up, hand-weed them occasionally, and thin them to three or four inches distance, to remain till October or November; then plant them out where they are to remain to flower: their roots will endure many years, increase in size, and the larger they are, the greater number of flower-stalks they produce, so as to exhibit a large shew of bloom.

DENTARIA, Toothwort, or Tooth Violet (*Dentaria*.)

This genus furnishes three hardy, herbaceous, flowery perennials, producing annual stalks twelve or eighteen inches high, adorned with many-lobed leaves and spikes of quadripetalous cruciform flowers.

Class and order, *Tetradynamia Siliquosa*.

Characters.] CALIX, four oblong, oval, deciduous leaves. COROLLA, four cruciform petals. STAMINA, four long and two short filaments, and erect heart-shaped antheræ. PISTILLUM, an oblong germen, thick style, and blunt stigma. PERICARPIUM, a long, taper, bivalvular, bilocular, pod, and many roundish seeds.

The species are,

¹DENTARIA *Pentaphyllos*.

Five-lobed Dentaria.] *Dentaria*, with upright strong stalks a foot and a half high, garnished with five-lobed digitate leaves, and terminated by loose spikes of blush-coloured flowers.

²DENTARIA *Enneaphyllos*.

Nine-lobed Dentaria.] *Dentaria*, with upright stalks a foot high, garnished with ternate trifoliate leaves, being composed of nine lobes by threes, and the stalks crowned by branches of purplish flowers.

³DENTARIA *Bulbifera*.

Bulbiferous Seven-lobed Dentaria.] *Dentaria*, with slender stalks a foot high, the lower

leaves pinnated and seven-lobed, the upper ones simple, and the stalks bearing bulbs at their sides, and the top crowned by clusters of purple flowers.

The flowers of all these three species are composed of four cruciform obtuse petals, and are collected into spikes or clusters at top of the stalks, appearing in summer, and are succeeded by plenty of seed.

The plants are all of the flowery tribe, perennial, hardy, and delight most in shade; they are therefore proper furniture for the borders of shady walks, and such like departments.

They are propagated by seed, and by parting the roots.—Sow the seed in autumn soon after it is ripe, or early in spring, in a shady border of light earth, and when the plants are three inches high, may be planted where they are to remain, and they will flower the year following. By parting the roots, it may be done in October or November, or early in spring.

The bulbs produced on the sides of the stalks of the *Dentaria bulbifera*, taken off and planted, readily become plants.

DIANTHUS, Clove Gilliflower, Carnation, Pink, Sweet William, &c.

This genus furnishes a grand collection of herbaceous, beautiful, flowery perennials and biennials, of hardy growth, for the pleasure-ground, all of them fibrous-rooted, crowned with leaves all the year, sending up flower-stalks annually from one to three feet high, adorned at top with very conspicuous, pentapetalous, solitary, and aggregate flowers.

Class and order, *Decandria Digynia*.

Characters.] CALIX is long, cylindrical, indented into five parts at top, scaly at the base, and persistent. COROLLA is in its single state, pentapetalous, with long narrow claws the length of the calix, but the limbs broad, plane, and their edges crenated. STAMINA, ten long filaments, and oval, oblong, compressed antheræ. PISTILLUM, an oval germen, two styles, and recurved acuminate stigmas. PERICARPIUM, a cylindric unilocular capsule, four-parted at top, and many compressed, roundish, angulated seeds.

There are many species of *Dianthus*, but not more than four that have any considerable merit as garden-flowers, each of which furnishing some beautiful varieties.

For distinction sake we shall treat of them under three different heads; first, the Gilliflower or Carnation kinds,—second, all the Pink

Pink kind,—and third, all the Sweet William tribe; all under the generical title of *Dianthus*.

First Head. The Gilliflower or Carnation kinds.

There is but one species of Gilliflower or Carnation, but which admit of a profusion of most elegant varieties, all very ornamental flowery plants, for the embellishment of the pleasure-garden, flowering beautifully in July and August, succeeded by abundance of seed in autumn.

The species is,

DIANTHUS Caryophyllus.

Caryophyllus, or Clove Gilliflower, including all the varieties of Carnation.] *Dianthus*, with many short trailing shoots from the root, garnished with long, very narrow, evergreen leaves, and amidst them upright slender flower-stalks, from one to three feet high, emitting many side-shoots, all of which, and the main stalk, terminated by large solitary flowers, having short oval scales to the calix, and crenated petals.

The varieties of this are very extensive, and unlimited in the diversity of the flowers.

Principal varieties are,

Common Clove Gilliflower—having a large, dark, red, sweet-scented flower, smelling fragrantly like cloves; hence it derived the name, and of which there are—Single Clove Gilliflower—Double Clove Gilliflower.

Carnation, sometimes called Coronation (Coronarius)—having a reddish single and double flower—Variegated red and white single and double flower—Variegated red, purple, and white single and double flowers—Variegated red, scarlet, purple, and white single and double flower—Variegated red, or purple above, and white underneath, single and double flowers;—and innumerable other intermediate varieties.

But these varieties (Variegated Carnations) are by the florists divided into four principal classes, according to their different modes of variegation, viz.

Flake Carnations—having only two principal colours, disposed in broad flakes or stripes quite through the petals.

Bizarre Carnations—having three or four different colours, red, purple, scarlet, &c. in different shades, variously disposed in irregular spots and stripes.

Piquette Carnations—having always a white ground, pounced or finely spotted with red, scarlet, purple, or other colours.

Painted Lady Carnation—having the petals a bright red, or purple above, and entirely white underneath.

Each of the above four principal classes, though tolerably permanent, admit separately of innumerable varieties, formed, both in respect to the lustre of the different colours, &c. as well as the different modes or dispositions of the stripes, spots, and other diversities, in being more or less striped with larger or smaller stripes, or with different colours in the same stripe, or all of one colour, the same is also observable in the spotted or pounced flowers, by the spots being either more frequent, or thinly scattered, or large or small, and such like variegations; and by which the florists form new varieties, acquired by raising some every year from seed; for from the seed of the varieties of each respective class indefinite numbers of new ones are annually gained, varying in some particular circumstances as above, from any that have before appeared, so greatly do they vary from seed. But it must be remarked, that out of a great number so obtained from seed, there may, probably, be but few that possess the requisite properties by which florists distinguish a fine Carnation. However, all good new varieties, of the above four principal classes, obtained among professed florists, are generally dignified with the name of some great personage, or that of the person who first raised them, or that of the place where they were raised; so that including the different parts of the kingdom, there may be many hundred different varieties, known in different places by different titles, as above, that it will be impossible to enumerate them here; observing, however, that all of them belong principally to one or other of the above classes; and that being first of all obtained accidentally from seed, they are afterwards propagated, and continued only by layers, &c. for so the seed of any particular sort, it is a hundred to one if any prove exactly like the parent; but by layers, every one retains all the properties of the mother plant. See their *Propagation*.

The flowers of this species and respective varieties, are, in their characteristic or single state, composed of five petals, but in the double flowers the petals are numerous, and continued quite to the centre; the doubles are also larger, and considerably more beautiful, and these only should be principally cultivated, which being all first obtained accidentally from seed, they are continued and increased at pleasure by layers.

The

The doubles are sometimes amazingly large, measuring frequently three or four inches diameter over the crown, especially those sorts called bursters.

But whole-blowers and bursters are common to most of the varieties, more particularly the flakes and bizarres.

The whole-blowers are such whose calix, or outer cup, is of long and of equal growth, and opens only at top regularly each way, for the free and equal expansion of the petals all around; and the flowers of this sort, though rather smaller than the bursters, are always more regular in their natural expansion, and require considerably the least trouble in managing their bloom.

Bursters are such, whose cup is large, and swollen as it were, and is very apt to burst open on one side, and the petals thereby break out of compass, and the flowers become very irregular; but by care in assisting it in due time, by tying and opening the calix a little on the contrary side, it may be made to blow regular, and will be very large and handsome.

But the whole-blowers are the best calculated for those who have but little time to spare, as they will always blow regularly, either in pots or the borders without any attendance.

The properties required to form a good Carnation are, that the stem or flower-stalk be moderately tall, i. e. from about eighteen to thirty inches high, of proportionable strength all the way up, and at the top so firm as to support the flower erect, or at least without nodding or hanging much downward. That the flower be large and double, i. e. have numerous petals quite to the very centre, these long, broad, and regularly spreading; and that when the flower is fully blown, it may be gradually rising in the middle in a spherical manner, and the whole expanding so regularly, that the circumference or outer rim be perfectly circular. The colours should be strong, lively, and elegant, the stripes and other variegations regular in every part, that no great disproportion may appear in the disposition of the colouring throughout the petals of the same flowers. These properties are principally expected in the fine varieties in pots, designed for stage flowers.

Their Use in Gardens, &c.

The fine varieties of this beautiful flower are in universal esteem among florists and all curious gardeners, and are of the list of prize

flowers, that being raised in their fullest perfection, are carried to florists' feasts, to shew for a prize, which practice is still much in vogue in many parts; and that the flowers usually brought to such places, being the production of many different artists, according to their utmost skill, there are often very curious exhibitions of them, in great variety, surprisingly large and fine.

The fine varieties are commonly cultivated in pots, for these reasons—first, that they may be readily moved to occasional protection of a frame or awning of mats, &c. from severe frost in winter; for although the plants are hardy enough to live through the winter fully exposed, yet, in severe seasons, they are sometimes so much cut, that they shoot but weakly; but by protecting them from the rigours of hard frosts, they are preserved in vigour, and they will consequently be better prepared for shooting, and will flower in greater perfection. Secondly, it is proper to retain the fine varieties in pots, in order that, when in bloom, they may be placed upon a raised stage, covered at top, calculated both to shew the flowers to more advantage, by being raised two feet from the ground, and by the top being covered, it defends them from the scorching rays of the noon-day sun, and from violent rains, &c. which would greatly impair their beauty, and hasten their decay.—And lastly, by placing the pots of plants upon a stand or stage, having the posts of which surrounded at bottom by small cisterns or pans of water, prevents creeping insects from coming at the posts thereof to ascend to the flowers, particularly ear-wigs; for these mischievous vermin would otherwise get into the bosom of the flower, and gnaw the bottom of the petals, that they would all drop out of the calix.

But a due quantity of the more common sorts should be planted to adorn all the flower-borders and the other conspicuous compartments of the pleasure ground; for they will thrive in any common soil of a garden, and will flower abundantly in tolerable good perfection; and where there are several different varieties, they will exhibit a delightful ornamental appearance for six weeks, i. e. from the beginning or middle of July until the latter end of August, being their general season of flowering.

Pots of these plants, as also of pinks and sweet-williams, may, by way of curiosity, be brought to bloom early in spring, by placing them

them in a hot-house or forcing-frame in January, February, or March. See FORCING-FRAME.

The Soil proper for their Culture.

With respect to soil, although all the varieties grow freely in almost any common garden earth, and in which produce beautiful flowers, yet they are generally superior in that of a light loamy nature, and of which kind of soil florists generally prepare a compost for their fine varieties intended for pots as follows:

Provide a quantity of loamy earth, of a light sandy temperate, from an upland or dry pasture field or common, taking the top spit turf and all, which must be laid in a heap for a year, and turned over frequently, as directed in the article COMPOSTS; and is then to be mixed with about one third of rotten dung of old hot beds, or rotten neat's dung, and a little sea-sand, forming the whole into a heap again, to lie three, four, or six months, and will be then excellent for use; and if one parcel or heap was mixed with one of these kinds of dungs, and another parcel with the other, for different seasons, it will make a change, and may be found very beneficial in promoting the size of the flowers.

The above compost is as good as can be for those plants, either in pots, or to form into beds.

This compost, or any other earth you may use for this purpose, should not be sifted, but only well broken with the spade and hands. See COMPOSTS.

Their Propagation by Seed.

By seed.—When great quantities of the plants of this species are required either to furnish large grounds, or for market, or that it is intended to raise new varieties, it is easily effected by sowing some seed annually in spring, in common earth, and from which the plants will rise abundantly; and as to varieties, you may always expect several new flowers of good properties from the plants of each sowing, and possibly not one exactly like those from which the seed was saved; and that from the seed of the finest varieties there will probably be many very indifferent, as well as good flowers, some single, some double, though the singles are always considerably more numerous than the doubles; but it is from the doubles only we are principally to select varieties for our purpose, which are marked when in bloom, to lay for propaga-

tion, and the most capital of which potted for the stage, &c. and the others will do for the common flower-borders.

The season for sowing the seed, is any time from about the 20th of March to the 15th of April.

It grows freely in a bed or border of common earth, of the quality of any light rich kitchen-garden mold; though curious persons often sow the fine sorts in pots or boxes, for the convenience of moving them in hot weather, to have only the morning sun; however, you will succeed in either method; and as to sowing on a bed or a border, may either sow it on the surface, and rake it lightly in, or may first rake the surface smooth, then sow the seed on the surface, and sift over as much light earth as will cover it a quarter of an inch deep: observe also the same method in sowing it in pots or boxes, giving moderate refreshments of water in dry weather; and the seed will germinate more freely, and the plants rise regular, and take a free growth.

The plants generally come up in a month after sowing: give occasional waterings and weeding, and in July they will be fit to prick out into nursery-beds, which prepare in an open situation three feet wide; and taking advantage of moist weather, prick the plants therein four inches apart, and finish with a general watering, which repeat occasionally till the plants have taken good root. Here let them remain till September, when they will be so well advanced in growth, as to require more room, and should then have their final transplantation into other three-feet wide beds of good earth, in rows lengthways the bed, nine inches asunder, and the same distance in the lines, placing them in the quincunx order; and here they are finally to remain all winter, and until they flower, and have obtained an increase of the approved varieties of doubles, by layers: and until which periods, all the culture they require is, that if the winter should prove very severe, an occasional shelter of mats, during the hardest frost, will be of much advantage, though not absolutely necessary; and in spring loosen the ground between them with an hoe, keep them always clear from weeds, and when their flower-stalks advance, tie them up to sticks, especially all those that discover by their large flower-pods to be doubles.

They will flower in June, July, and August, at which times, as soon as the singles

X x

and

and doubles are distinguishable, all the singles may be drawn out to make room for their betters, the double varieties.

When these are fully blown, examine their properties; the finest may be marked for stage flowers, and the others as furniture for the borders; all of which may be increased by layers the same year, to treble or perhaps six or eight times their number or more, since each good plant will furnish from three or four, to ten or twelve shoots from the bottom proper for laying, each of which takes root, and becomes a new plant the same season; and each of these again will in their turn furnish the like number of shoots the following years, for the same work of propagation; and so each variety may be thus annually increased to great numbers, and every plant so obtained of each respective variety, retains all the properties exactly of the mother plant, which is never the case of those propagated by seed; though from seedlings all our fine flowers are always first obtained.

Therefore as soon as the seedlings shew bloom, proceed to the work of propagation by layers of all the doubles among them, or at least as many of them as you shall approve; and the following is the method of laying them.

Their Propagation by Layers.

By layers.—We observed above, that the propagation of these plants by layers is the only method by which we can with certainty continue any particular variety, either new or old; since every layer, becoming a new plant, always produces a flower exactly in size, colour, and character, as that of its parent; and that being layed in summer, they form roots in six weeks, and be fit to transplant, and each produce flowers the year following, as well as each furnish a farther supply of shoots for more layers.

The proper parts for layers, are those leafy shoots arising near the crown of the root, which, when about five, six, or eight inches long, are of a proper degree of growth for layers.

The general season for this work is June, July, and beginning of August, as then the shoots will be arrived at a proper growth for that operation; and the sooner it is done, after the shoots are ready, the better, that they may have sufficient time to acquire strength before winter: those layed in June and July will be fit to take off in August and

September, so will form fine plants by October.

The method of performing the work is as follows.—First provide a quantity of small hooked sticks for pegs, three or four inches long, with which to peg the layers down to the ground; also get ready, in a barrow, a quantity of light rich mold, to raise the earth, if occasion, around each plant; and provide also a sharp penknife. Having all these ready, then proceed to the work of laying; first strip off all the leaves from the body of the shoots, and shorten those at top an inch or two evenly, and then fixing upon a strong joint about the middle of the shoot, and on the back or under side thereof, cut with your penknife the joint half way through, directing your knife upward, so as to slit the shoot up the middle almost to the next joint above; by which you form a kind of tongue, on the back of the shoot, observing that the swelling skinny part of the joint remaining at the bottom of the tongue must be trimmed off, that nothing may obstruct the issuing of the fibres, for the layers always form their roots at that part; this done, loosen the earth around the plant, and, if necessary, add some fresh mold, to raise it for the more ready reception of the layers; then with your finger make a hollow or drill in the earth to receive the layer, which bend gently down horizontally into the opening, raising the top upright, so as to keep the gash or slit part of the layer open, and with one of the hooked sticks peg down the body of the layer, to secure it in its proper place and position, still preserving the top erect, and the slit open, and draw the earth over it an inch or two, bringing it close about the erect part of the shoot; and when all the shoots of each plant are thus layed, give directly some water to settle the earth close, and the work is finished, repeating the waterings often in dry weather; and in five or six weeks the layers will have formed good roots, when they should be separated with a knife from the old plants, and planted in beds or pots, as may be convenient, in the following manner.

Taking off, and transplanting the Layers.

The layers, as above observed, are generally well rooted in six weeks after laying, which you will observe by opening the earth a little, and examining the bottom, or root part, and if it has emitted plenty of fibres, they should be taken off, and planted out separately, to form distinct plants.

They

They must be cut or separated with a knife from the old plant, gently raising them out of the earth with the point of a knife or trowel, so as to preserve the fibres or roots of the layers as entire as possible; and when thus taken up, cut off the naked sticky part at bottom close to the root, and trim the tops of the leaves a little; they are then ready for planting, either into beds or pots, but rather into nursery-beds of good earth, about six weeks, and then the fine sorts may be potted; therefore chusing a bed or border of rich light earth, let it be then neatly digged, and the surface raked smooth, and here plant the layers with a dibble, at six or eight inches distance, give directly a good watering, and repeat it, in dry weather, every day or two, for a week or a fortnight, when the plants will have taken fresh root, and begin to advance in growth.

In this bed let them take their growth till October, then those of the fine varieties may be potted in small pots (forty eights) for moving to occasional shelter from hard frosts till spring, then transplanted into large pots to remain to flower; therefore, at the above-mentioned time in autumn, take up the layers of the prime sorts from the nursery-beds, with small balls of earth about their roots, plant one in each small pot, and give a moderate watering, and place them in a warm situation in the full air till November, then move them to occasional shelter, as directed in their winter culture.

Some persons plant the layers at once into large pots in autumn; but these are not so convenient to remove to shelter in winter, as small pots, because they take up much room in a frame, &c. besides, by having the layers in small pots all winter, when they receive hardly any growth, and transplanting them into large pots of fresh earth in spring, it proves very beneficial to the plants. See *their Spring Culture*.

The more common sorts may either at the above time, in autumn, be transplanted into the borders or other compartments of the pleasure-ground, where they are to remain to flower, or may be continued in the beds until spring; and then a due quantity may be disposed in the borders, or retained in the same bed, for flowering, as may be convenient.

Their Winter Culture.

In November the fine varieties in pots should be moved to a sunny sheltered situation

for the winter, and if placed in a frame, &c. to have occasional protection from hard frost, it will be of much advantage; therefore where there are any garden frames at liberty, the pots may be placed close together therein, or if the bed is raised three, four, or six inches with light dry earth, sand, or ashes, and so plunge the pots in it to their rims, it will be a greater protection for their roots, covering them occasionally with the glasses in hard frosts, &c. but for want of frames, a bed prepared as above, may be arched over with hoops, to be covered occasionally with mats.

Under either of those shelters the plants are to be covered with glasses or mats only in time of severe frost and great snows; but must enjoy the full air in all open weathers, by having all covering entirely off, and a moderate frost can no ways affect them, for if much covered, it would draw them up weak and tender. Do not however omit, in severe weather, to afford them the above shelter, which will preserve the plants in greater health and vigour than if fully exposed to all weathers during the winter.

Be careful also that the earth in none of the pots is rendered very wet by the hole at bottom being too close stopped to detain the moisture.

Thus continue your care of the potted plants till spring, and then shift them into large pots to remain to blow, as directed in their spring culture.

In respect to those in the open beds, although they commonly stand the winter tolerably, yet if you have any spare frames, or the beds arched over, to be covered with mats or long dry litter in severe frosts, it will be of much advantage.

Their Spring Culture, shifting into larger Pots, &c.

In the latter end of February, or some time in March, the layers in the small pots, or such as are in beds, and that you intend shall blow in pots, should be transplanted with balls into the large pots, where they are to remain for flower.

The pots proper for their reception for flowering should be sixteens, but not less than twenty-fours; for they should be nine or ten inches at least in the clear at top, but if a foot the better, that there may be due room to lay the layers, at the proper season, for a further increase, which is an essential point to be considered. The pots being ready, put some pieces of tile or oyster shells over the holes

at bottom, and fill them half way with earth; then turn the plants out of the pots, &c. with the ball of earth about their roots, and after taking away a little of the earth around the sides of the ball, place one plant in each of the large pots, filling up the vacancy round the ball with more fresh compost, bringing it also close up about the body of the plant, which should stand nearly as high as the rim of the pot; and finish each pot with a moderate watering.

Many persons plant two plants in each large pot; but when there is only one, they flower stronger, make stronger shoots for layers, and there is more room to lay them.

The plants being thus potted, place them in a sheltered sunny situation in the full air, and in dry weather supply them with water twice or thrice a week, and here let them remain till they are considerably advanced, towards flowering, then the fine sorts may be placed on the Carnation stage: where there is such conveniencies observe as follow.

Summer Culture, placing them on the Stage, and Management when in Bloom, &c.

During dry warm weather continue the care of watering those in pots every day or two. Likewise clear out all weeds, and at times lightly stir the surface to prevent the earth from binding, which will be beneficial to the plants, and preserve an air of neatness.

In May and June the flower-stems of the plants will advance a-pace, when sticks should be placed for their support, which should be two feet and half, or a yard long, either round or square, but perfectly straight and tapering from the bottom; such as are sold about London at the lath-renders and turners, for nine-pence or a shilling per dozen; sharpening the lower end, thrust one down by every plant, to which tie the flower-stems in a neat manner, which repeat at different times, according as they advance in height.

In June or beginning of July the plants will be considerably advanced towards flowering, when those intended for the stage should be placed thereon, both to be out of the way of creeping insects, particularly ear-wigs, which, as before observed, eat the petals off at their base, to the destruction of the flowers; so to prevent their depredation, the posts or supporters of the stage should be surrounded at bottom by small cisterns of water, as hereafter directed, that the vermin cannot come at the posts, to creep up to the flowers; and

that by placing the plants on a stage, having the platform eighteen inches or two feet high, the flowers are viewed to more advantage; and if there is erected an awning over the top, supported four feet above the platform, the flowers being hereby screened from the vehement heat of the mid-day sun, and defended from heavy rains, are continued much longer in beauty.

Some Carnation stages are constructed upon very elegant plans, both to render them useful and ornamental.

But as to the general construction of a common Carnation stage, it is formed entirely of slight timber-work, thus—A boarded platform is erected, at eighteen inches or two feet height, formed by two ranges of planks, to contain two rows of pots lengthways, proportionable to the number intended to be placed thereon; and which is supported on posts, ranged either in one row along under the middle of the platform, or in two ranges, one on each side; and over the top is erected a roof of open work, five or six feet high, to be covered with painted canvas, &c. for the protection of the flowers, supported either by a range of neat posts on each side, or by one row, ranging along the middle between the planks of the platform, which is the most eligible; the roof may be formed either archways, or like the ridge of a house, having the arches or spars about a foot asunder, and stiffened by thin slips of deal carried across them the whole length of the stage; and the roof thus formed may be covered either with coarse canvas painted white, or strong brown paper painted the same colour with white lead, or with strong white paper brushed over with linseed-oil to render it proof against wet, or in default of either of these, may cover it with neat garden-mats, lengthways, either of which being designed only just to screen the flowers from the scorching sun and great rains, that their beauty may be continued as long as possible.

All the wood-work of the stage should be painted white, both to preserve it from the weather, and give it a more lively appearance.

In constructing Carnation stages, some are so curious as to contrive sticks for the support of the flower-stalks, fixed to the work of the stage, by means of small neat rails carried along lengthways the stage, just over the place where each row of pots stand, and from which rails upright sticks, half an inch thick,

thick, are carried to another such rail above, placing them at such distances, that there be two to each pot, and so train the flower-stems up to the outside of the sticks.

With respect to the cisterns of water above mentioned, to surround the supporters of the stage, they are formed by earthen or leaden pans, about fifteen inches wide, and three or four deep, having a hollow or vacancy in the middle six inches wide, like a socket, to receive the posts, and is formed by a raised rim in the middle, equal in height to that of the circumference; and the hollow or socket so formed is to receive the bottom of the posts quite through to the ground, and the space between the outer and inner rim is filled with water; so that each post standing in the middle of such a cistern, sufficiently guards against creeping insects, for they will not attempt to cross the water.

These cisterns may be had at any of the potters that make garden-pots; and if you choose them of lead, every plumber knows their construction.

But as making the above described Carnation stage may not be convenient to every one, I shall describe one of a more cheap and easy construction. Provide some flat earthen pans about fifteen or eighteen inches diameter, and three or four deep, which place by pairs opposite two feet apart, and six or eight feet between each pair lengthways; and in each of these pans, whelm a large garden pot bottom upward, and across each pair of pots lay a flat piece of timber, two feet six inches long, and two or three inches thick; then having long planks, lay these across the timbers lengthways, in two rows, and your stage is formed, then place two rows of pots upon the planks, and fill the pans with water, to keep off insects.

For want of a covered stage to screen the flowers, you may contrive a kind of small umbrellas or round-spreading caps, either of tin or strong paper or canvas, nine or ten inches diameter, one for each plant, having a socket in the middle to receive the tops of the support-stick; those umbrellas which are formed of tin are the best, and may be had at the tin-ware shops; but if you make them of paper or canvas, first form little round frames, having the rim formed with slips of lead, wire, cane, &c. the above width, with cross slips of the same materials, contriving a socket of lead or tin in the middle for the support stick to go quite through, as just ob-

served; and upon these frames paste or sew some strong thick paper or canvas, which paint with oil-colour, that they may stand the weather; either of which covers are placed over the flowers by running the support stick up through the hole or socket in the middle, and resting the cap upon a piece of wire put across the stick, at such height from the flower as to screen it effectually from the sun and rains.

Give attention to continue to tie up neatly the flower stalks of the plants in general, as they advance in stature. When they are arrived at their full height, the curious in Carnations support them erect at top with wires, having a small eye or ring at one end, for the reception of the flower-stalk, so put the other end into holes made in the support-sticks; these wires should be five or six inches long, and several holes are made in the upper part of the sticks, the first at the height of the bottom of the flower-pod, the others above that, an inch or two distant, and place the wires in the holes lower or higher, that the eye or ring may be just even with the base of the calix, to support the flower in an upright position; and by drawing the wire less or more out, the flower is preserved at any distance from the support as shall seem necessary, to give it proper room to expand; and if two or three of the like wires are placed also in the lower parts of the support-sticks, placing the stem of the flowers also in the eye of the wires, all the tyings of bafs, &c. may be cut away.

To have as large flowers as possible, curious florists clear off all side-shoots from the flower-stem, suffering only the main or top buds to remain to flower.

When the flowers begin to open, attendance should be given to assist the fine varieties, to promote their regular expansion, particularly the large burster kinds, they being apt to burst open on one side, and, unless assisted by a little art, the petals will break out of compass, and the flower become very irregular; therefore attending every day at that period, observe, as soon as the calix begins to break, to cut it a little open at two other places in the indentings at top, with narrow-pointed scissars, that the openings be at equal distances, and hereby the more regular expansion of the petals will be promoted; observing, if one side of any flower comes out faster than another, to turn the pot about, that the other
side

side of the flower be next the sun, which will also greatly assist the more regular expansion of the flower.

Likewise when intended to blow any particular fine flowers as large and spreading as possible, florists place spreading paper collars round the bottom of the flowers, on which to spread the petals to their utmost expansion; these collars are made of stiff white paper, cut circular, about three or four inches over, having a hole in the middle to receive the bottom of the flower, and one side cut open to admit it; which is to be placed round the bottom of the petals within side of the calix, the leaves of which are made to spread flat for its support; and then spread or draw out the petals upon the collar, to their full width and extent, the longest ones undermost, and the next longest upon these, and so of the rest quite to the middle, observing that the collar must no where appear wider than the flower; thus a Carnation may be rendered very large and handsome; but we do not recommend the practice as absolutely necessary, only mention it as the practice of those who have much leisure time, and who take a particular pleasure in exhibiting very large Carnations; and indeed, a carnation that expands regular in their natural way, whether whole-blower or burster, although they do not appear so large as the collared flowers, yet I should think they must appear more natural and beautiful; and even the largest bursters may be made to blow very regular with a little attendance, just to slit the calix, as hath been directed, when they begin to burst.

But as the whole-blowers always blow regular without any trouble of opening the calix, and although not so large as the bursters, yet have great beauty, and are the most proper for general culture, for those who have much other business to mind.

Continue the care of watering the pots, which in dry hot weather will be necessary every day, being essential to promote the size of the flowers, and increase the strength of the shoots of the plants at bottom, for layers.

And as in June and July the layers will be arrived at proper growth for laying, should also be layed to continue your increase of the approved varieties, and so continue laying the shoots of each year's growth at the above season, managing them always as before directed.

As to the border Carnations, i. e. such as you intend shall flower in borders or beds

in the full ground, any of the varieties may be employed, and their propagation both by seed and layers is the same as already directed; the season for transplanting them into the places of their final destination for flowering, is also either in autumn or spring, that is, October or beginning of November for the autumn planting, and for that of the spring, any time in March, or first fortnight in April; removing them with little balls about their roots, planting them about two feet from the edge of the border; and as to culture, it is principally tying up the flower-stalks as they advance in stature, and to make layers of all the approved sorts annually, in June or July, for propagation.

General Observations-

I would just hint here, of Carnations in general, whether for pots, or as border-flowers, that their propagation and general culture is always the same as already directed, under the two respective heads of Propagation by Seed, and by Layers: raised and treated according to these directions, becomes a good plant the same season, fit for transplanting finally in autumn or spring following, either into pots or the open borders, and they will flower in the utmost perfection the succeeding summer.

And that the general season for planting out finally all sorts, seedlings and layers from the nursery-beds, &c. into the places where you design they shall flower, either in pots or the full ground, is October or beginning of November, or in spring anytime from the latter end of February to the beginning or middle of April, removing them with small balls about their roots, plant them singly, that is, one in a place, and always finish with a watering to settle the earth close about the roots.

Always in May and June give attendance to tie up the flower-stalks to support-sticks, repeating it occasionally; for this looks neat to the eye, and promotes the size and regularity of the flowers.

Every spring it may be proper to sow some seed to obtain varieties.

Every summer, in June or July, make layers for increase of all the approved double sorts, whether Clove or Carnation, of the Flake, Bizarre, Piquette, or Painted Lady kinds.

Note, they may also be propagated by cuttings and pipings, as directed in the

propagation of Pinks, but these are not so successful in general as layers.

As to the old roots, having a good increase of new young plants by layers, you may either eradicate them, or use them in different parts of the pleasure-ground in vacant spaces of large borders, &c. for being perennial, they will endure several years, though the new plants always afford the largest and finest flowers.

Saving the Seed.

All the varieties of Carnations, both single and double flowered plants, produce abundance of seed, which ripen freely in August and September.

But to have the greater chance of obtaining seeds for raising fine new varieties, you should mark some of the finest flowers when in bloom, and all those of bad colours, or of other bad properties, should be removed to prevent any admixture of the farina. For the same reason, it is also of importance for the purpose of seed, to keep the flakes, bizarres, piquettes, &c. as far distant as possible, whereby each of these sorts may, even from seed, be preserved tolerably permanent, though each in itself profuse in many varieties of its own kind.

It is also worth observing, that seedling plants are generally more prolific in good seed, than such as have been long increased from year to year by layers.

The ripening of the seeds should be attended in August and September, to gather the pods in due time, as they ripen in dry weather, which spread on paper to dry, then rub them out and put them up in dry papers till sowing-time in spring.

Second Head of Dianthus.

DIANTHUS Comprising those kinds of Dianthus commonly denominated Pinks.

The principal species of the Pink kind are distinguishable from the Carnation tribe of the first class, by the shoots and leaves being considerably shorter, smaller, more numerous, and tufted; and the flower-stalks shorter, the flowers smaller, and more crenated.—All of which species are hardy herbaceous fibrous-rooted plants of the flowery tribe; though there are but two species esteemed for general culture, one the Common Pink, a perennial; the other, the Chinese or Indian Pink, an annual, both of which, admitting of several eminent varieties of great merit for the ornament of the pleasure garden.

There are however about four species, which may be admitted into the flower garden, three perennial and one annual.

Class and order the same as the Carnation. See the *First Head*.

The first three are perennials, viz.

DIANTHUS Deltoïdos.

The Common Pink.] Dianthus with numerous short leafy shoots crowning the root, in a tufted head close to the ground, closely garnished with small narrow leaves, and from the ends of the shoots many erect flower stalks from about six to fifteen inches high, terminated by solitary flowers, having lanceolate double scales to the calix, and crenated petals, and with single and double flowers of different colours, and variegations in the varieties.

This species and its following varieties are the sorts of Pinks the most commonly known and cultivated, all of which are perennial.

The most material varieties are,

Common Red Pink.—Produces flower-stalks eight or ten inches high, and small red flowers.

Damask Pink.—Produces flower-stalks six or eight inches high, and reddish purple flowers.

White Pink.—Producing flower-stalks eight or ten inches high, and very white flowers.

White fringed Pink.—Produces flower-stalks six or eight inches high, and pure white flowers, having the edges of the petals considerably jagged or fringed.

Pheasants-eye Pink.]—Producing firm flower-stalks eight or ten inches high, and large whitish and bluish-coloured flowers, having a dark purple spot or eye in the middle, hence called Pheasants-eye Pink.

Of this sort there are many varieties obtained from seed, all of them generally retaining the purple eye in the middle, but differing from each other in size, doubleness, colour, and the size and colour of the eye, &c. So that the different intermediate varieties have names according to the fancy of the person who first raised each new variety. And of the different varieties, there are whole blowers and bursters, the latter are generally very large, but the whole-blowing flowers are preferable for the regularity of growth.

Red Cob Pink.—Producing flower-stalks twelve or fifteen inches high, and large bright red flowers.

Of each of the above varieties of this species *Dianthus Deltoïdes*, there are single and double flowers, the singles are but little regarded,

garded, as enough of them may be obtained from seed, and from which also the doubles were first obtained; but the doubles being large multipetalous and more beautiful, are the only sorts worth general culture, and which being once obtained, they may be continued and encreased abundantly by layers, slips, cuttings, and pipings. See their *Propagation*.

As to the flowering season of all the varieties, some of the small sorts, such as the damask, and white shaggy Pink, often flower in May, or early in June, which are succeeded by the others, continuing in succession till July, all of which furnish plenty of seed in autumn.

²*DIANTHUS Virgineus.*

Maiden Pink, commonly called Matted Pink.]

Dianthus with numerous low trailing leafy shoots, crowning the root in a matted tuft, close to the ground, garnished with short, awl-shaped deep green grassy leaves; and many erect flower-stalks six or eight inches high, terminated each by one red flower having very short calycinal scales, and crenated petals.

Variety.] With flesh coloured flowers.

³*DIANTHUS Glaucus.*

Glaucous or Grey-leaved Mountain Pink.]

Dianthus with many low leafy shoots crowning the root in a cluster close to the ground; very short narrow grey coloured leaves, and many erect branchy flower-stalks eight or ten inches high, terminated by large white flowers, having a purple circle in the bottom; and with four lanceolate calycinal scales, and crenated petals.

Variety.] With double flowers.

A N N U A L.

⁴*DIANTHUS Chinenfis.*

Chinese, or Indian Pink.] *Dianthus* with upright firm flower-stalks, branching erectly on every side, a foot or fifteen inches high, and all the branches terminated by solitary flowers; having awl-shaped spreading calycinal scales equalling the tube, and indented petals; and with single and double flowers of different colours, and variegations in the varieties.—Flowering from July till November.

Varieties are.] With bright red single and double flowers—with purple single and double flowers—white single and double flowers—variegated single and double flowers; of each of which are many intermediate varieties in respect to the shades, and disposition of the colourings, especially of the variegated

kinds, which are in general lively and elegant; the doubles in particular are singularly beautiful, being large and very full of petals to the very centre, all of which varieties may be considered both as annual and biennial, for they rising from seed in spring, flower the same year in summer, and commonly perish in winter, especially in moist soils, but if planted in dry warm ground, sheltered from severe frost, the roots will continue two years, and flower strongest the second season of their bloom: they all flower abundantly from July till the beginning of winter, furnishing plenty of seed in autumn, from which the plants are raised plentifully in spring, either in the full grounds or in hot-beds, to bring them more forward.

All the flowers of the above four species and their varieties, are in their single state composed of five petals, but in their compound or double state, the petals are multiplied, and the first and fourth species are very prolific in double varieties, which are often large and very full of petals, continued in many series to the centre; and both singles and doubles arise from seed, but often ten or twenty or more singles to one double.

They flower in June and July, the annual sort continues till autumn, and all of them produce seed in plenty.

Use in Gardens, &c. of all the Sorts.

All the above four species of the Pink tribe, and respective varieties considered, as hardy flowering plants are proper furniture for the compartments of the pleasure ground; but the first species, *Dianthus Deltoides* and varieties, have superior merit both for the beauty and fragrance of their flowers, and are the sorts in greatest estimation for general culture, as plants of ornament; and as each plant of any tolerable size produces numerous flower-stalks, all terminated by flowers, renders them choice furniture for the common flower-borders, or to embellish the vacant spaces in the fronts of small shrubby clumps. The second and third species are also retained in many gardens, to encrease the variety in the collection of flowering perennials. And the fourth species, *Dianthus Chinenfis*, has great merit, not only for the liveliness of their beautiful flowers, but also for the long continuance of their bloom, which in the same plant is often continued in plentiful succession three or four months, but have no fragrance.

Observe that, as all the perennial Pinks, being both of a tufty and spreading growth, and

and produce many flower-stalks, they should be disposed singly, only one plant in a place; but the annual sort being different, it is rather proper to dispose them in patches of three or four plants in each.

Any of the sorts may also be cultivated in pots occasionally, to place in fore-courts, or to adorn any other principal compartment.

Sometimes the Common Pink and varieties are employed to form edgings to beds or borders, but as in one year they are apt to spread greatly out of compass, and become irregular, they are not well adapted for that use—However, if they are used for that purpose, the edging should be cut in on each side once or twice a year, with garden sheers.

Great quantities of the Common Pink and varieties are, when in bloom, brought to the London markets for sale, each with a small ball of earth about their roots, which sell from one to two or three shillings per dozen of plants; but when in pots, double or treble that price; or if they are forced in hot-beds for an early bloom, as mentioned before, they fetch considerably more.

About London great quantities of the double varieties of the Common Pink are forced by aid of artificial heat, for an early bloom in February, March, and April, for the supply of Covent-Garden market; the pheasant-eye kinds are most commonly used, but any of the sorts will succeed: they must be potted, and in January, February, or March, placed either in the hot-house, or in a forcing-frame, worked either by bark or dung heat. See FORCING FRAME. The plants thus forwarded sell from about a shilling to half a crown per pot, according to the earliness of the season, and merit of the flowers.

Propagation, &c. of the Perennial Sorts.

The first, second, and third species, are propagated by seed, layers, slips, cuttings, and pipings.

By Seed.—Great numbers of plants may be raised with the utmost facility by seed, in a bed or border of common earth in spring, which will all flower the year following, and among which there will probably be many double flowers, and some new varieties, particularly of the first sort, Common Pink.—The proper season for sowing is, March and April. Chuse a bed of rich light earth, dig it neatly, and form the surface even, then sow the seed and rake it in; or may practise as directed for the Carnations; the plants will

appear in a month or five weeks, which, in June or July, when two or three inches high, plant out into nursery beds till October or spring following, and then to be transplanted with balls into the places where they are to flower, or they may remain in the beds for flowering, as observed of the Carnation seedlings. When they shew bloom, the singles may be drawn out to give room for the double kinds, which you may continue and encrease abundantly, by layers, slips, cuttings, &c. and all the plants so raised, produce flowers, having all the properties of those of the mother plant.

By Layers.—The same method is to be observed for those as for the Carnations, and June, July, and beginning of August is the time to perform this work, or managing them in every respect as the Carnation layers: or if in spring, some large plants which have spread considerably, have all their shoots covered with earth an inch or two deep, without taking pains to slit or tongue them, as in laying Carnations, many of them will emit fibres and be well rooted, and fit to transplant in autumn, each a distinct plant.

By Slips.—In spring, any old plants of the approved varieties may be encreased by dividing them into many slips, either by slipping off the younger shoots from the sides of the main ones, which, though destitute of roots, many of them will readily emit fibres and grow; or may divide, or slip the plants quite down to the roots, where practicable, so as to preserve as many fibres to each slip as possible; but slips by either method, if done in February, March, or April, will readily succeed, and form good plants by the end of summer, observing, that the short bushy plants are more eligible for slipping, than such that are long and straggling; and slips from about three or four, to six or eight inches long, will succeed. Having therefore slipped a proper quantity for planting, let them be planted in a bed or border of good earth, six inches asunder, putting them down almost to their tops, give them water directly, and repeat it occasionally, in dry weather; they readily take root, grow freely, and form good plants by Michaelmas, when, or in spring after, they may be transplanted with balls, where you design them to flower.

By Cuttings.—June and July is the best time for this work, when the young shoots of the year will be advanced a proper length to form cuttings of two or three inches long, which

which planted will readily grow, and form good plants the same year.

Observe therefore, when the shoots of the same year's growth are of a proper length, and proportionably firm, not the long slender ones, but those of somewhat robust growth; and of which take off a proper quantity four or five inches long, then trim off all the lower leaves, and cut those at top pretty short, and then at about two or three inches from the top, cut them clean through a joint horizontally, casting the lower part away, and reserve the top for planting, which, if two or three inches long, is a proper cutting; being thus prepared, then having some rich light earth broken perfectly fine, either in a bed, border, or in large pots, making the surface smooth, plant the cuttings as follows: take them one by one by their tops, and thrust the lower end into the earth they will readily make way for themselves; so putting them down full half way, and an inch or two asunder, and give directly a good watering out of a pot with the rose on, they should then be covered air-tight with bell or hand glasses, which will greatly facilitate their rooting; nor need they be taken off till the cuttings are so far rooted as to begin to grow, nor need they be much shaded; and the watering, which must be often repeated, may be applied around the outside of the glasses, a sufficiency of which will soak to the mold within for the benefit of the cuttings; but for want of glasses they may be shaded in the heat of the day with mats, and frequently watered.

They will thus be rooted in a month or six weeks, and advance fast in growth, and should then be fully exposed; and, when well rooted and advanced considerably at top, should be transplanted, gently raising them out of the earth with their roots as entire as possible, and prick them in a bed of good earth five or six inches apart, to remain till autumn, or spring following; then may be removed to the places allotted for them to flower.

By the above method the London gardeners generally propagate all the choice varieties of double pinks, which is not only the most certain and expeditious, but form much better plants than those by slips; and to keep up their stock, always propagate vast quantities every summer by this method: an expert hand will plant a thousand per day, and not one in fifty miscarry.

By Pippings.—This is nearly the same as

by Cuttings, only, that instead of cutting off at a joint, take the head of the shoot in betwixt the finger and thumb, and draw it asunder at the joint, by which it often comes out of its socket as it were, leaving a hollow like a pipe, hence it is called Pipping; trim the bottom of each even to the joint, they are then to be planted and managed exactly as directed above for the cuttings.

Propagation, &c. of the Annual Sort.

The Dianthus Chinenfis.—Being rather of the Annual tribe, or at most biennial, is always raised from seed annually in spring, tho' if the plants have a dry warm soil in winter, they will abide two years, and produce stronger flower-stems, more numerous, and larger flowers than the same year's seedlings.

As the plants however, are easily raised in great plenty from seed, and as they are rather apt to go off in winter, a fresh supply should be annually raised; the seed grows freely in a bed of natural earth, sown any time in April, or beginning of May, either on the surface, and raked in, or first rake the ground smooth, sow the seed and sift earth over, to a quarter of an inch deep, or sow it in drills that depth; but to bring the plants as forward as possible, you may sow the seed in a hot-bed, with other annuals of similar quality, such as African marigold, China aster, &c. See ANNUAL PLANTS.—And in May or June, when the plants of either method of sowing are a month old, about two or three inches high, prick them out from the seed-bed into a bed of good rich earth, in rows six inches asunder, giving water, and occasional shade till rooted; and after having a month's growth here, they will be of a proper size for final transplantation, taking them up with balls, and planting them into the different compartments of the pleasure-ground, in patches of three or four plants in each, in which they will appear more conspicuous in flower than if disposed singly.

Sowing the Seeds of all the Sorts.

All the sorts of Pinks of this class afford seed plentifully in August and September, which should then be gathered in the pods in dry weather, spread to dry and harden on papers, then rubbed out and put up for the spring service.

Third Head of Dianthus.

DIANTHUS, &c.—Comprehending those sorts of Dianthus commonly called Sweet-Williams.

This

This class comprises but one species, which admits of numerous elegant varieties, all hardy, herbaceous, fibrous-rooted, flowery perennials, distinguishable from the two former classes of *Dianthus*, by having larger shoots, much broader leaves, and, by the flowers growing all at top of the stalks in aggregate clusters.

Class, order, and characters the same as the other species of *Dianthus*, See the *First Head*.

The species is,

*DIANTHUS Barbatu*s.

Bearded Dianthus, commonly called Sweet-William.—*Dianthus* with many thick leafy shoots crowning the root in a cluster close to the ground, garnished with spear-shaped evergreen leaves, from half an inch to two inches broad; and upright firm flower-stems branching erectly two or three feet high, having all the branches and main stem crowned by numerous flowers in aggregate clusters of different colours, and variegations in the varieties.

The varieties may be divided in two classes. Narrow-leaved and broad-leaved kinds, the narrow-leaved sorts being remarkable for being the most productive of variegated flowers, and many doubles.

Varieties are,

Narrow-leaved kind.—With narrow leaves and deep red flowers—With pale red flowers—Pale red, and flesh-coloured flowers—Purplish white eyed flowers—Snow-white flowers—White and flesh-coloured flowers—White and purple flowers—White spotted flowers—Red flowers and white borders, called Painted Lady Sweet William; and with many other intermediate shades of colours and variegations, and which frequently vary in the flowers of the same aggregate; there are also single and double flowers of each variety. Among the doubles of this class of narrow leaves, is that sort called the Mule, having a bright red double flower in smallish aggregates, said to have been accidentally produced from the seed of a Carnation, impregnated by the effluvia of a Sweet William, hence is called the Mule.

Broad-leaved kinds.—With broad leaves and tall deep red flowers—Tall flesh-coloured flowers—Pure white flowers—White dotted flowers—Striped leaves and red flowers—Large double rose-coloured sweet-scented flowers—Large double deep purplish burster flowers—Double variegated flowers.

All the varieties of both classes are hardy herbaceous, evergreen perennials, rising the first year with a large bushy tuft of leafy shoots, continuing green the year round, and the second year shoot up flower stems, producing flowers in June and July, succeeded by abundance of seed in autumn.

The corolla, in all these varieties of each class is, in its single characteristic state, composed each of five petals, but in the double flowers it is large and multipetalous, and both single and double are obtained from seed; though probably ten, twenty, or more singles to one double, and the narrow-leaved kinds are generally the most productive of double, which are more commonly variegated than of plain red or white colours.

But both singles and doubles are extremely elegant, and in a great degree ornamental garden flowers, which terminating the stalks and branches in large clusters, like umbels, continuing six weeks in bloom, but have no fragrance; so that their merit consists entirely in their ornamental appearance for the decoration of the borders, and other parts of the pleasure-ground, in which they are exceedingly conspicuous and grand; and as they are all so hardy as to prosper in any common soil of a garden, and may be raised abundantly from seed in the full ground, a good stock of them should always be maintained by an annual sowing, and the fine doubles by layers, &c. See their *Propagation*.

Some of the large double sorts may also be cultivated in pots, to place occasionally, to adorn fore-courts, or other principal districts of a garden.

The plants although in general of several years duration, yet, after the first year of flowering, the shoots generally become long, straggling, and of unsightly, dwindling growth, so that a supply should be raised every year from seed, or layers, for the one year-old plants are always close and bushy, and flower much stronger than those older standing; and the following is their method of propagation:

Their Propagation.

They are propagated by seed, layers, and slips, all of which is easily effected in the full ground.

By Seed.—March and April is the season for sowing, and the seed is sold cheap enough at all the nurseries and seed-shops: sow it in a bed or border of light earth broadcast, and rake it in; in a fortnight after the plants will

come up, which in June or July should be transplanted into nursery-beds of common earth, in rows six or eight inches distant, to remain until autumn or spring following, then taken up with balls about their roots, and planted in the places where they are to flower.

By this method great quantities of the plants are raised in gardens about London for sale, which are generally marketable just as they begin to shew bloom, and which, of the single kinds, fetch but from six-pence to a shilling per dozen of plants; but often more than that for one plant of the doubles.

By Layers.—June and July is the proper season, and the same method is to be observed in every respect as for the carnations, which see, so it will be unnecessary to repeat it here. This is the only method of propagation to continue the fine double-flowered varieties, which being layed, give frequent waterings in dry weather, and they will be well rooted in six or seven weeks; then should be separated from the old plant, and planted in a bed of light soil; and in October some of them should be potted, to move to occasional shelter from frost, for although the doubles are almost as hardy as the single kind, yet being more choice it is necessary always to have some of the finest in pots, that they may have protection in severe winter weather, observing the same as for the choice carnations.

By Slips.—February, March, April, and October, is the time for this work, observing, if it is to be performed upon the year-old plants, they must be slipped quite down to the roots, so as to have fibres to each slip, then may plant them at once where they are to flower; but these never make so good plants as seedlings and as layers, nor do they generally flower so strong.

Saving the Seed.

The Sweet-williams are remarkably prolific in seed, particularly all single varieties, and from which both single and double sorts are obtained.

If you would cultivate only the finest varieties, the flowers which have the most beautiful colours, both of the plain and variegated kinds, should, when in full bloom, be marked from which to save seed: if any ordinary sorts grow near them, let them be removed to prevent an admixture or emission of the effluvia or male-powder in the flowers of the chosen sorts, which might occasion a

great variation, for by observing this you may continue some of the varieties tolerably permanent.

Let the branches of seed be gathered in dry weather, and after lying a few days in the sun to dry and harden, beat it out, and put it up in papers, &c. till spring, for sowing.

DIBBLE or DIBBER. A simple but useful implement of gardening, used for planting out all sorts of young plants, &c.

The best sort of Dibble is that made of the tree of an old spade, having the head or top handle entire, and the shank twelve or fifteen inches long, made gradually tapering to a point at the lower end, and which to be perfectly complete should be shod with a thin socket of iron eight or ten inches in length, made also tapering to a point at bottom; for an iron-shod dibble makes the holes for the reception of plants much easier, cleaner, without clogging, and more expeditiously than entirely of wood, which is apt to clog with earth, and greatly retard the work of planting.

The above sort of dibble is proper for planting out almost all sorts of young plants, particularly the fibrous-rooted kinds, and all sorts of cuttings, &c.

But besides the above kind of narrow-pointed dibble, for planting out young plants, &c. I should also advise to have a blunt-pointed one for planting large kinds of seeds, and bulbous roots, such as broad beans, potatoes, large kinds of nuts, &c. and the bulbs of crocus, narcissus, tulips, and other bulbous kinds, that by being rounded at the end, makes a hole to receive the above sorts of large seed and roots plump to the bottom; whereas the narrow-pointed dibble makes the hole deeper than it is capable of admitting them, so that there will be a vacancy under the seed or root, in which water might stand to their prejudice, especially in winter; besides, when the seed or root goes clean to the bottom, it is certainly more effectual to its free growth.

It may indeed be advanced, that the narrow-pointed dibble will answer the same purpose, by striking a little earth into the hole to fill up the narrow part at bottom, previous to planting the seed or root, but this in a hurry may often be omitted, and takes up more time: but the blunt-ended dibble makes the hole at once to admit the seed or root always plump to the bottom.

But as to planting bulbous roots by dibble, though

though often practised, yet if they are to be planted together in beds, I would rather advise drilling them in, that is, draw drills three or four inches deep with an hoe, so place the roots plump bottom downward in the drills, and earth them over. See the respective articles of HYACINTH, NARCISSUS, DRILLS, &c.

DICTAMNUS, White Dittany, or *Fraxinella*.

It consists of one hardy, herbaceous, flowery perennial, rising two or three feet high, crowned by spikes of pentapetalous flowers.

Class and order, *Decandria Monogynia*.

Characters.] CALIX, five small, oblong, pointed leaves. COROLLA, five irregular petals. STAMINA, ten rising filaments, and four-cornered antheræ. PISTILLUM, a pentagonous germen, short incurved style, and acute stigma. PERICARPIUM, a quinquelocular bivalvular capsule, and roundish hard seeds.

The species is,

DICTAMNUS Albus.

White Dittany, commonly called Fraxinella.]

Dictamnus, with thick, penetrating, perennial roots, collected into a head at top, sending up erect stalks annually two or three feet high, garnished with pinnated alternate leaves, of three or four pair of oblong stiff lobes, terminated by an odd one, and the stalks crowned by long, pyramidal, loose spikes of flowers.

Varieties of this are] With white flowers—with red flowers, striped with purple—with short spikes of flowers.

The flowers of all the varieties have five unequal petals, i. e. two of them turning upward, two oblique on the sides, and one turning downward, appearing in the latter end of May and in June, succeeded by ripe seeds in September.

They are very ornamental garden flowers, so merit a place in every collection of flowery perennials, and they succeed in any of the common borders.

The whole plant imparts a balsamic odour, when bruised, and the roots are used in medicine.

All the varieties are propagated by seeds, in a bed or border of common earth, sowed in autumn or spring; but the autumn sowing, i. e. in September or October, generally rise strong the spring following, which in autumn after, when the leaves decay, should be planted in a bed or border six inches apart, to remain a year or two, then transplanted into

the flower-borders, where they will flower the succeeding summer, and will endure many years, increase exceedingly in magnitude, and flower every year stronger.

All the necessary culture is, to cut down the decayed stalks every autumn, dig the ground in winter or spring, and keep them clean from weeds in summer.

DIGGING.—Digging ground may be considered as a sort of garden-tillage, or necessary preparation of the soil for the reception of all sorts of seeds and plants, and which should be duly performed annually, either in autumn, winter, or spring, particularly for every new crop, and is also beneficial to crops of perennial standing, whether esculent flowers or shrubs, &c.

This operation is performed two different ways.—Plain digging,—and digging by trenches, commonly called trenching.

Plain Digging.—This is beginning at one end of any piece of ground, bed, or border, and dig it one spade deep, right back spit and spit regularly to the place where you finish; the method is this, begin as aforesaid at one end of the piece of ground you intend to dig, and with your spade open a trench quite across, one good spade wide, and one deep, carrying the earth to the end or place where you finish; then keeping your face to the opening, proceed to digging one spade deep regularly from one side of the piece to the other, turning the spits neatly into the trench, and the next course against these, and so keep digging straight back, spit and spit, still preserving an open trench, a good spade width and depth, between the dug and undug ground, that you may have full room to give every spit a clean turn, taking all the spits perpendicularly, and not take too much before the spade, especially in stiff land, or where the surface is full of weeds, or is much dunged; so giving every spit a clean turn, the top plump to the bottom, and the bottom to the top, that the weeds or dung on the surface may be buried a due depth, and that the clean fresh earth may be turned up.

As you proceed break all large clods, and preserve an even surface, carrying both sides and middle on equally, unless one side shall be hollow; then carry on the hollow side first, in a kind of gradual sweep, inclining the spits of earth rather that way, which will gradually raise that side, and reduce the high one, observing the same if both sides are high and the middle hollow, or both sides hollow and the

the middle high, always keeping the lower ground advancing gradually before the higher, by which you will always maintain a uniform level, whether horizontal or declining.

The same should also be observed in beginning to dig any piece of ground, that if one corner is much lower than the other, carry on the lower part somewhat first, in a kind of easy sweep or slanting direction, as far as necessary; likewise in finishing any piece of digging, that if one corner shall be low and the other high, carry the digging gradually round upon the lower side, so as to finish at the highest corner; and having digged to the end, or that part of any piece of ground where you intend to finish, then use the earth digged out of the first trench to make good the last opening equal with the other ground.

In plain digging dunged ground, if the dung is quite rotten, you may either dig clean through, giving each spit a clean turn, to bury the dung plump in the bottom of the trench; but if you cannot readily do this, trim the dung a spade's width at a time into the furrow or open trench, and so dig the ground upon it, which is rather the most effectual method, whether rotten or long fresh dung.

In the course of digging, all root-weeds that are perennial should be carefully picked out, particularly couch-grass and bear-bind, the *Convolvulus Sepius*, for the least bit of either will grow, encrease greatly in summer, and prove most troublesome weeds.

But slight rooting weeds on the surface being turned clean to the bottom, will rot, and never trouble you again.

Digging by trenches, or trenching.—This is called trenching, because the ground is digged in regular trenches, trench and trench, of two or three spades width, and one, two or more deep in the following manner:

Begin at one end of the piece of ground, and open a trench by line and spade two full spades width at least, and one or two deep, and wheel the earth to the place where you shall finish, then mark out a second trench of the same width, pare all weeds on the surface into the bottom of the first, and then beginning at one end of the second, and standing side-ways to the other, dig it the full width and depth as above, turning the earth into the first trench, observing, that if you go two spades deep, dig the top spit along first, then beginning again at the end, dig the second course; then mark out a third trench, dig it

into the second, and so proceed trench and trench to the end of the ground, remarking, that if you would have each course of spits in the several trenches their full depth, it is proper to shovel up the crumbs or loose earth at bottom of each course; so may dig either one spade deep and the crumbs, or two and crumbs as shall seem necessary, but by no means go below the good soil; and one good full spade deep, with a good paring at top, is, for common trenching sufficient for general crops of most sorts of plants, and more than that is only necessary on particular occasions, and for particular plants, which will always be hinted in the respective articles.

I would however observe, that by trenching occasionally two spades deep where the soil admits, by turning the bottom spit to the top, renews the soil; and by turning the exhausted or worn-out earth to the bottom that depth for two or three years, gives it a sort of respite to recruit new vigour in its vegetative quality, that being again trenched up to the top will produce crops the more abundantly, and in greater perfection.

It is indeed good culture when practicable, to trench two moderate spades deep, with or without the crumbs, for carrots and parsnips and such like roots which strike deep into the ground, and for liquorice three full spades deep is necessary, for the roots, the useful part, often strike down four feet deep.

The merit of trenching in general, is superior to plain digging for principal crops, or any plantations, in that the top soil, all weeds and dung are more effectually buried in the bottom, and the fresh soil at bottom more readily turned to the top, which is of considerable importance in the growth of all seeds and plants; therefore in digging ground for any general crops or plantations of young trees, &c. I should advise to dig it principally by trenches one good spade deep at least, or two occasionally, especially when necessary to renew the soil, or as you shall judge proper for long-rooted esculents, as carrots, &c. or plantations of choice fruit trees.

In all trenching, whether one, two, or more spades deep, always, previous to digging, pare the top of each trench two or three inches deep or more, with all weeds and other litter into the bottom of the open one, which not only makes clean digging, and encreases the depth of loose soil, but all weeds, as also the seeds of them that may have scattered on the surface are regularly buried at such a depth,

depth, that the weeds themselves will rot, and their seeds cannot vegetate.

In trenching dunged ground, if you trench but one spade deep bury the dung of each trench regularly in the bottom; but if two spades deep, it will be eligible to bury the dung between the two spits, that is, trimming back the dung, dig the first course, turning it into the bottom of the open trench, then trim in the dung upon that, and dig the second course and turn it in upon the dung, and so proceed trench by trench.

When intending to trench for spring crops, or even for any autumn or winter plantation, it is good culture to perform it some considerable time before, to lie fallow till the time for sowing or planting, to meliorate by the weather, but more particularly for spring crops, so that if it is trenched up in rough ridges in winter, to lie till spring, and then levelled down, proves very beneficial to plants of all sorts.

I would also advise, that all trenching in winter, intended for spring crops, be trenched up in rough ridges, that is, instead of forming a level surface, lay the earth of each trench in a sharp ridge, as you advance with the work, laying the spits of earth rough, that the soil may lie hollow to receive the greater benefit from the sun, air, and frost, to meliorate and enrich its quality.

The above method of ridging the trenches, is universally practised by the London kitchen-gardeners, even if the trenching is done in spring, and is to lie but a week, or two or three days, for it is soon levelled down when to be sown or planted, and it greatly improves the ground.

The ridges are soon levelled down in spring, or when the ground is wanted for sowing or planting, observing to chuse dry weather for this work, levelling them regularly ridge and ridge lengthways, stirring all the ground, and preserve an even surface; and if the ground is for sowing with small seeds, do not level down much more than you can sow the same day, for fear of rain coming to render the surface cloggy, or the sun and winds dry it too much, as most land is always in best order for sowing while it is fresh stirred, for it not only falls to pieces more readily in raking, to cover the seed more effectually, but fresh stirred land promotes a quick and free germination in the seed.

Gardeners that have large grounds often hire the digging by the rod, the prices generally according to the nature of the

ground, whether light, loose, clean, and easy to be digged, or of a stiff nature, and whether it is clean or foul with weeds, or not dunged, or dunged, and whether by plain digging, or digging by trenches.

The prices by plain digging, that for light clean free-working ground, is, about London, commonly two-pence, or two-pence halfpenny per rod; and if dunged, three pence. But stiff stubborn-working land is often three-pence or four pence without dung; and where ground is very full of perennial weeds, such as couch grass, bear-bind, and the like, which should all be picked out by hand, an extra allowance is generally given per rod, a halfpenny or penny, according as the ground is less or more foul.

The prices by trenching is, that for one spade deep, and a top paring, commonly from two pence halfpenny to four pence, according to the nature of the ground, and whether dunged, or clean, or foul with weeds, though clean free-working ground is generally digged with dung one spade deep for three pence, and if two spades deep, from four pence to six pence, or eight pence.

A man will dig by plain digging, of light, free-working clean ground, eight, ten, or twelve rod a day, from six to six, though in some of the light clean ground about London, I have known a man turn up fifteen or twenty rod a day, from five to seven; on the other hand, in stiff stubborn soils a man may work hard for six or eight rod in a day of twelve hours. And that digging by trenches, or trenching, if only one spade deep, without the crumbs, or shovelling at bottom, a man will dig almost as much as by plain digging; and by double digging, or two spades depth, from four to six rod a day may be good work, though in harsh-working ground, a man may labour hard to get up three or four rod a day.

DIGITALIS, Fox Glove.

This genus furnishes hardy, herbaceous, tall, flowery, biennials and perennials for the pleasure-ground, and a tender shrubby exotic for the green-house, all of them adorned with long, spear-shaped, simple leaves, and long spikes of large bell-shaped flowers.

Class and order, *Didynamia Angiospermia*.

Characters.] *CALIX* is five-parted and persistent. *COROLLA* is monopetalous, bell-shaped, tubular, and with the limb slightly four-parted, having the upper lip spreading and emarginated, and the under one largest. *STAMINA*, two long and two short filaments inserted

inserted into the base of the Corolla, and bipartite antheræ. PISTILLUM, an acuminate germen, simple style, and acute stigma. PERICARPIUM, an oval, bivalvular, bilocular capsule, and angular seeds.

There are about four herbaceous and one shrubby species, retained in our gardens as plants of ornament.

The first four are herbaceous and hardy.

¹DIGITALIS *Purpurea*.

Purple Common Fox Glove] Digitalis, with an upright strong stalk three or four feet high, garnished with long, rough, hairy leaves, and terminated by a long loose spike of large purple flowers ranged along one side, having oval leaves to the calix, and obtuse corolla, with an entire upper lip.

Variety] With white flowers.

²DIGITALIS *Lutea*.

Yellow Fox Glove.] Digitalis, with an upright strong stalk two or three feet high, garnished with long, spear-shaped, smooth leaves, and the upper part with a long spike of yellow flowers ranged along one side, having the leaves of the calix spear-shaped, an acute corolla, and bifid upper lip.

Varieties are] With small yellow flowers—with large yellow flowers—with narrow leaves and small yellow flowers.

³DIGITALIS *Ferruginea*.

Ferruginous, or Iron-coloured Fox Glove.] Digitalis, with an upright stalk five or six feet high, adorned with narrow leaves three inches long, and terminated by a very long erect spike of iron-coloured flowers, having oval leaves to the calix, and the lower lip of the corolla very long.

⁴DIGITALIS *Thapsi*.

Thapsi, or Purple Spanish Fox Glove.] Digitalis, with an upright stalk a foot and a half high, garnished with very long, woolly, rough, veined, decurrent leaves, and terminated by a short spike of purple flowers.

Shrubby and tender.

⁵DIGITALIS *Canariensis*.

Canary Shrubby Fox Glove.] Digitalis, with a shrubby, upright, branchy stalk rising five or six feet high, spear-shaped, rough leaves four or five inches long, and half as broad, and with all the branches terminated by loose spikes of flowers, having the calycinal leaves spear-shaped, and an acute two-lipped corolla.

The flowers of all these species of Digitalis are of one bell-shaped petal, moderately large, and mostly ranged along one side of the stalk. See the *Characters*.

Of these species the first sort grows wild in most parts of Britain, but all the others are of foreign growth. All the herbaceous kinds are hardy, and prosper any where, but the shrubby sort requires shelter of a green house in winter.

The four herbaceous species are biennial and perennial, all of them rise first with a large tuft of leaves, crowning the root, and amidst them rise the stalks in spring, flower in June, ripen seeds in autumn, and the stalks and leaves soon after decay, and sometimes also the root, especially of the first sort, which is seldom more than biennial.

All the herbaceous species may be employed as plants of ornament in the embellishing the different compartments of the pleasure-ground, and will prosper in any common soil and exposure.

The shrubby sort claims a place among the green-house exotics, is a very pretty flowering plant, often continuing its bloom from May till October.

Propagation, &c.

The herbaceous sorts are raised from seed in the common ground, sown in autumn or spring, but which if sown in autumn are commonly more successful; when the plants are come up three inches high, prick them out at six inches distance, to remain till autumn, then transplant them where they are to flower.

The shrubby sort is also raised from seed, sowed in pots of rich earth in autumn, &c. and placed in a garden-frame to have occasional protection from frost, excessive rains, and cold; and when the plants are two or three inches high, plant them separate in small pots, and afford them shelter during cold weather, and place them in the green-house in winter.

DIOSMA, African Spiræa.

This genera comprises several low shrubby exotics for the green-house, garnished with small entire leaves, and numerous, small, quinquepetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX is five-parted, plane at the base, and persistent. COROLLA, five oval, obtuse, erect petals, and a coronated quinquefid nectarium. STAMINA, five filaments, and oval, erect antheræ. PISTILLUM, a germen crowned by the nectarium, simple

simple style, and obsolete stigma. PERICARPIUM, five united capsules, each having one oblong, depressed, smooth seed.

The species are,

¹DIOSMA *Oppositifolia*.

Opposite-leaved Diosma] Diosma, with a shrubby stem, branching irregularly three or four feet high, garnished with awl-shaped, acute leaves, placed opposite, and numerous, small, white flowers all along the sides of the branches.

²DIOSMA *Hirsuta*.

Hairy Sweet-scented Diosma] Diosma, with a shrubby stem, branching regularly five or six feet high, narrow hairy leaves, placed alternate, and clusters of white flowers at the ends of the branches.

³DIOSMA *Rubra*.

Red Flowering Diosma] Diosma, with a shrubby stem branching three feet high, narrow, acute, smooth leaves, keel-shaped underneath, and spotted on both sides, and red flowers.

⁴DIOSMA *Ericoides*.

Heath-leaved Diosma] Diosma, with a shrubby stem branching three or four feet high, narrow spear-shaped leaves, convex underneath, and imbricated two ways.

All these plants are natives of Africa, and require the shelter of a green-house here in winter. They are all very ornamental during their bloom, and most of them impart a fragrant odour, so are worthy of a place in every curious green-house collection.

Propagation, &c.

All the sorts are propagated plentifully by cuttings in spring or summer, planting them in pots, several in each, and plunge them in a hot-bed, they will be well rooted in two months, and may then be potted separately, and managed afterwards as other green-house shrubs. See GREEN-HOUSE PLANTS.

DODECATHEON, American Bear's-ear, formerly *Meadia*.

It furnishes one low, flowery perennial for the pleasure ground, adorned with umbellate clusters of monopetalous flowers.

Class and order, *Pentandria Monogynia*.

Characters.] CALIX, a many-leaved involucre, and each floret having a monophyllous, five-parted, permanent cup. COROLLA, many florets, forming a sort of umbel, each floret monopetalous, cut into five retroflexed segments. STAMINA, five short filaments, and arrow-pointed antheræ, connected into a beak. PISTILLUM, a conical germen, slender style, and obtuse stigma. PERICARPIUM,

an oblong, oval, unilocular capsule, containing many small seeds.

The species is,

DODECATHEON *Meadia*.

Virginian Dodecatheon, formerly called Meadia.] Dodecatheon, with a yellow perennial root, crowned by several long smooth leaves, six inches long and two or three broad, and between them erect flower stalks eight or ten inches high, each terminated by an umbellate cluster of quinquefid, retroflexed, purple flowers. See the *Characters*.

This is a hardy perennial, flowers very ornamentally in May, ripens seeds in July, and the stalks and leaves decay in autumn, so are renewed from the root annually in spring.

It will succeed in any of the common borders, but is the most prosperous in a somewhat shady situation.

Propagation.

Its propagation is by seed, and by off-sets of the roots.

By Seed.—Sow the seed in autumn, soon after they are ripe, in a shady border, or in pots, moving them to occasional shade in hot weather, the plants will come up in the spring, and when their leaves decay, plant them on a shady border, six or eight inches apart, to stand a year; then transplant them into shady flower-borders.

By Off-sets.—In August or September, when the leaves decay, is the properest time to remove the roots, and take off the slips for encrease, planting them again directly, and each off-set will flower the following summer.

DORONICUM, Leopard's-Bane.

The plants are hardy, herbaceous perennials, for the large departments of the pleasure-ground, they obtaining from eighteen inches to three feet stature, terminated by large compound flowers.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] CALIX 'compound radiated flower, having the general cup formed of a double series of long narrow leaves. COROLLA, many tubular hermaphrodite florets form the disc, and ligulated females the radius. STAMINA, five filaments and cylindric antheræ. PISTILLUM, a germen, small style, and in the hermaphrodites an indented stigma, in the females two, which are reflexed. PERICARPIUM, none. SEMEN, a single furrowed downy seed under each floret.

The material species are,

¹*DORONICUM Pardalianches.*

Greatest Leopard's-Bane.] *Doronicum*, with thick, fleshy, knotty, penetrating roots, crowned by a cluster of heart-shaped hairy leaves on long foot-stalks, and amidst them upright channelled stalks, three feet high, garnished with a few amplexicaule leaves, and each terminated by one large compound radiated yellow flower.

²*DORONICUM Plantagineum.*

Plantain-leaved Leopard's-bane.] *Doronicum* with thick fleshy roots crowned by oval acute-pointed leaves; and between them upright stalks two feet high, and alternate branches, surmounted by large compound yellow flowers.

³*DORONICUM Bellidiastrum.*

Bellidiastrum, or Wild Daisy-leaved Leopard's Bane.] *Doronicum* with short hairy leaves, and upright simple naked stalks a foot high, terminated by one white and yellow flower.

Variety.—With broad leaves, taller stalks, and red and white flowers.

All these plants are hardy and perennial in root, but annual in stalk, which rise in spring, flower in May, ripen seeds in July, and decay to the root in autumn.

The flowers are universally compound and radiated. See the *Characters*.

These plants may be employed in the large departments of the pleasure ground, where many plants of easy culture are required to encrease the variety; for they will grow any where, and where the seeds scatter many young plants will rise naturally.

Propagation.

They are easily propagated by seed, and by their spreading roots; either of which may be performed in autumn or spring.

Sow the seed on the surface, and rake it in, and when the plants are two or three inches high prick them in beds nine inches distance, which transplant in autumn where they are to remain.

Off-sets of the roots taken off in autumn, or early in spring, will flower in May following.

DRACOCEPHALUM, Dragon's-head.

It consists of herbaceous perennials and annuals for the pleasure-ground and greenhouse, rising with upright stalks, from about eighteen inches to three feet high, garnished mostly with entire leaves, and whorled spikes of small monopetalous ringent flowers.

Class and order, *Didynamia Gymnospermia.*

Characters.] *CALIX* is monophyllous, tubular, and permanent. *COROLLA* is monopetalous and ringent, with large inflated chaps, having an obtuse arched upper lip, and the lower one trifid. *STAMINA*, two long and two short filaments, and heart-shaped antheræ. *PISTILLUM*, a four-parted germen, slender style, and bifid reflexed stigma. *PERICARPIMUM*, none. *SEMEN*, four naked seeds lodged in the Calix.

The principal species are,

¹*DRACOCEPHALUM Virginianum.*

Virginian Perennial Dracocephalum.] *Dracocephalum* with upright, four-cornered stalks a yard high, adorned with spear-shaped sawed leaves, opposite at each joint; and terminated by erect spikes of purple flowers in July and August.

²*DRACOCEPHALUM, Ruyschiana.*

Ruyschiana, or blue-spiked perennial Dragon's-head.] *Dracocephalum* with an upright square stalk two feet high, garnished with very narrow smooth entire leaves; and terminated by whorled spikes of large blue flowers, having small bractæ under each whorl; it flowers in June, and the seeds ripen in autumn.

³*DRACOCEPHALUM, Moldavica.*

Moldavian annual Dracocephalum, or Moldavian Balm.] *Dracocephalum* with upright branchy stalks a foot and half high, garnished with oblong deeply-sawed leaves, and terminated by whorled spikes of blue flowers; and the whole plant emits a very balsamic fragrance:

Variety.—With white flowers.

Both the varieties flower in July, and the seed ripens in September.

DRACOCEPHALUM, Canariense.

Canary sweet-scented perennial Dracocephalum, commonly called Balm of Gilead.] *Dracocephalum* with upright square perennial stalks three or four feet high, garnished with compound leaves of three or five sawed lobes, and short spikes of pale blue flowers, appearing most part of summer, and the whole plant emits a strong balsamic odour.

The first three species are hardy, the first two of which are perennial, but the third is annual, all of them may be employed as plants of ornament, of which the first and second have the most merit as flowering plants, though they may be all employed to good advantage in forming variety in extensive grounds, and will prosper in any common soil.

The

The fifth sort, *Balm of Gilead* is somewhat tender, requiring shelter of a green-house or garden-frame in winter, by which care it will retain its stalk and leaves the year round, so may be considered as an herbaceous-shrubby evergreen; it will however sometimes live in the full ground in a warm dry border, in mild winters, but this is not always to be depended on, therefore should keep them principally in pots, to move to occasional shelter in winter, but they only want protection from frost; great quantities of this plant are cultivated by the setting gardeners about London for the markets, where they are ready sale, at six pence or nine pence per pot.

Propagation.

The first sort may be raised from seed, and by parting the roots, but it propagates plentifully by the latter method, which may be performed in autumn, or early in spring.

The second sort is raised plentifully from seed sown in a bed of light earth in April, and when the plants are two or three inches high, prick them out at six inches distance, giving occasional water, and shade from the sun till rooted, so to remain here till October; then transplant them with balls into the borders, and other compartments of the pleasure-ground, observing, that it is proper to raise some fresh plants every two years, to succeed the old ones.

The third sort and variety, being annual, are raised every year from seed, sown in spring in small patches in different parts of the borders where the plants are to remain to flower. See **HARDY ANNUALS**.

The fourth sort is propagated easily by seed and by cuttings.

By Seed.—It may be sowed in autumn or spring, the autumn sowing will sometimes rise the same season, or if not, they will arise early in spring, and be forwarder than the spring sowings; they should be sown in pots of light rich earth a quarter of an inch deep, and sheltered in a frame, or glass case, occasionally in cold weather; and when the plants are two inches high, transplant them into separate small pots.

By Cuttings.—Cuttings of the stalks and branches about five or six inches long, planted any time in summer, either in a shady border, or plant several in large pots, moving them to occasional shade, and give waterings in dry weather, they will readily take root, and towards autumn may be planted in separate pots.

DRILL-SOWING, &c. In gardening, drills are straight narrow openings, formed in the earth with a hoe, from half an inch to five or six deep, for the reception of the seeds and roots of certain plants, which succeed best by that mode of culture.

Many sorts of esculents succeed by this method, as for example, all sorts of peas, and kidney-beans should always be cultivated in drills, for as the seed being rather large, by forming drills an inch or two deep for their reception, they are more conveniently sowed, and covered regularly at a proper depth with earth; and that the drills being in straight ranges two or three feet asunder, the plants consequently rise in rows that distance, whereby there is due room between the rows, to hoe the ground, to destroy weeds, and to loosen the soil, and draw it up occasionally on each side of the plants to strengthen them, and forward their growth; likewise when their produce is ready, their standing distant in drills allows room to go in between, to gather the crops without damaging the plants: broad-beans are also sometimes drilled in, though they are more commonly planted with a dibble; however, in drills two or three inches deep they may be planted to great exactness, and covered all an equal depth, allowing the drills three feet distance at least: asparagus plants are also planted more commodiously in drills six inches deep, than by any other method. Parsley, coriander, chervil, and all small fallad-herbs, such as cressies, mustard, &c. should also be sown principally in drills half an inch deep, as in which, the herbs are more easily cleaned, and more readily gathered for use. Spinach is also sometimes sowed in shallow drills, but more especially when cultivated between rows of other plants, as that of broad-beans, early cabbages, &c. it however should be sowed thin, otherwise the plants will draw each other weak; but I would rather advise the main crops of this plant to be sowed principally broad-cast over the surface of the ground, and raked in, and the plants hoed out to four or five inches distance. Beet having large seed, may be sown in inch-deep drills, in order, that they may be more effectually buried an equal depth. See the respective articles.

Many sorts of the larger seeds, nuts, &c. of trees, shrubs, and herbaceous plants, may also be sowed in drills an inch or two deep, in proportion to their several sizes.

Bulbous, and tuberous flower-roots are al-

so planted with great facility and exactness in drills of due width and depth; but these kind of roots are most commonly planted with a dibble; I should however, rather recommend the drilling, especially for such that are to be cultivated in continued rows, or in beds, proportioning the width and depth of the drill to the size of the respective roots; as for example, if for crocus, snow-drop, winter-aconite, anemone, ranunculus and the like, two or three inches wide and deep is sufficient; but for the larger kind, such as hyacinths, narcissus, tulips, lilies, &c. from three or four, to five or six inches depth is necessary, and from six to twelve inches between the rows; placing the roots bottom downward plump in the bottom of the drills at the same distance, and draw the earth evenly over them; but for more particulars, see the respective articles.

With respect to the method of drawing or forming drills, this should generally be performed by hoe and line; that is, set a line as tight as possible, then with a common hoe held corner-ways, with the edge close to the line, draw the drill along accordingly, from half an inch to five or six deep, as the different sorts of seeds and roots shall require, as exhibited in the respective articles.

Though drills for some particular small seeds, may be drawn with the hoe flat-ways, i. e. the edge downward, so as to make a broad flat-bottomed drill, half an inch, or an inch deep; which, for instance, may be more particularly necessary for the different sorts of small-sallad herbs, spinach, &c. when intended to raise them in drills, and for many kinds of flower seeds sown for transplantation.

But for seeds of tender plants, which may require the aid of hot-beds, and if necessary to sow them in drills, as a hoe cannot be introduced, the ends of the two first fingers, or that of a short flat stick, an inch or two broad, will form a proper drill.

As soon as the seeds or roots of any sort are sowed or planted in drills, draw the earth over them evenly, either with a hoe or rake, or with the hand for the very small or more delicate sorts; though for the large kinds, such as peas, kidney beans, broad-beans, &c. may turn the earth in upon them expeditiously with the feet alternately, being careful to cover all an equal depth, and trim the top of each drill clear from stones and clods, so as to leave a smooth surface.

DUNGS. In gardening there are two admirable properties in Dungs, viz.

The one is to repair the decays of worn-out or exhausted soils, and to meliorate and fatten the earth and render it fertile: the other is to produce a certain degree of heat when formed into hot-beds; which, in some measure supplies the office performed by the heat of the summer's sun, by producing crops of choice plants, fruits, and flowers in winter, or early in spring, that could not be obtained in the natural ground before summer; the former of which properties, (as manure) is effected both by new and old or rotten Dungs; and that of various sorts, but the latter property (for hot beds) is only to be found in one particular sort, i. e. horse-dung, including the wet litter and Dung together, as it comes from the stables, and while it is newly made, before it rots and loses its heat.

Dungs for Manure.—Various sorts are recommended and used, according to the qualities of the soil they are designed to restore, meliorate, and enrich.

As for example; some lands are very moist, heavy, stubborn, and cold; to improve which, some Dungs are of a hot light quality, as that of horses, sheep, and pigeons, &c. tho' for gardens, horse or stable Dung, tolerably rotted, either alone, or mixed with light materials, is the best of all to use in any considerable quantity for such land: on the other hand, some ground is light, dry, and hot, and requires moist, fat, and cooling Dungs, as that of oxen, cows, hogs, &c. to render the soil fatter, and more compact to retain its virtue. However, a mixture of all these, i. e. horse, and neat or cow Dung, &c. tolerably rotted, will suit almost every sort of soil, or either of them alone, especially if thoroughly rotten, will prove beneficial to most kinds of garden land.

Horse-dung, however, is certainly the best improvement for cold land that can be procured, and may be used successfully both new and rotten; not however used new or strawey for carrots, parsnips, or other esculent roots of similar growth, but for any other above-ground crops; new horse-dung just as it comes from the stable, may be used to much advantage in cold moist land, which in such soils frequently succeeds better than that which is quite rotten, as that of old hot-beds, or of the like nature.

We may also consider horse-dung the most useful of any for gardens, and is the most common Dung used as manure in many places, especially after having rotted in dunghills, or having

having been previously used for hot-beds in winter and spring, for early and tender crops; which crops being all gone by autumn, or winter following, when the Dung of the hot-bed will have become rotten and buttery, and is then carried off as manure, into the different departments of the garden, &c. and when thus rotted, is beneficial for all sorts of soils, and is very enriching.

And as to cow or oxen Dung, although it is particularly beneficial in light loose soils, yet, when well rotted it will also prove good manure for any; and with this and horse or stable-dung, as also hogstye-dung together, mixed, makes an excellent manure for most sorts of land.

Hogs Dung being very fat, is by some recommended as the most beneficial of all sorts of Dungs, and, when well rotted, has often proved excellent for fruit trees, in a light soil, especially for apples and pears, but when thoroughly rotted, may be used to advantage for all sorts, in light dry land.

Sheep and deer Dung have been found great improvers of cold clayey land.

The Dung of pigeons and other poultry being hot and full of salts, is found good for cold wet clayey lands, but before using, it would be an advantage, if exposed abroad in the dung-hill some considerable time to rot, sweeten, and to mollify the fiery heat natural to those Dungs; and if then mixed with light earth, sand, or ashes, to keep it from clinging, and then, after having lain six, eight, or twelve months, strew it over the ground in autumn or winter in moderate quantities, being dug in lightly, it will tend much to facilitate vegetation in cold heavy soils.

Human ordure, mixed with other Dungs, and earths, by way of compost, and exposed to the air some time, will prove beneficial to cold, sour, stubborn land.

For other sorts of Dungs, &c. used as manure, see MANURE.

All Dungs used as manure, should be applied principally, either in autumn, winter, or spring; and if it is horse or neats Dung or a mixture of both, or of hog's Dung, or the like, it should be laid at least from about three to six inches thick all over the surface; but on poor land, if double that thickness it will prove the more beneficial to the ground; but the hot fiery Dung of poultry should be used more sparingly, and that, only to cold, heavy land.

In digging or trenching dunged ground, the Dung should be buried one spade, not more, so that if you trench two spades deep, always bury the Dung betwixt the first and second spit.

Dungs for hot beds.—Horse-dung, together with the wet litter of their stalls, is the only sort capable of producing the effect of heat requisite for hot-beds, but which property is found only in that which is newly made, or at least that have not laid so long on the dung-hill as to begin to rot considerably, and has quite expended its heat. Preparatory to forming this Dung into hot-beds, the necessary quantity should be cast up in a heap, shaking and mixing the long and short well together, and here it should remain a week, twelve days, or a fortnight, to prepare all the parts to an equal quality, observing, if the Dung is new and strawey, it will require to lie longer than older or short Dung; and if the heap is turned over once or twice, the rank, unwholesome steam and burning quality, will evaporate more effectually. See HOT-BEDS, &c. &c.

DWARF TREES, these are fruit trees grafted near the root, that they may form heads, not more than from about four to six or eight feet high.

Under this head may be considered not only Dwarf-standards, but also all sorts of Dwarfs for espaliers, and walls, which are also grafted or budded low, to provide branches near the ground, so as to cover every part of the espalier or wall, from the bottom upward, most of which sort of Dwarf-trees are grafted or budded upon Dwarf stocks, or such as are but moderate shooters, particularly for Dwarf-standards, to preserve them as dwarfish as possible. See STOCKS. And in which, the graft or buds are inserted, within about six, eight, or twelve inches of the bottom, and the first shoots from the graft or bud, are in spring, when a year old, headed down to five or six eyes, to force out lower shoots to form the first set of branches near the root, as a foundation for the upper part, and by shortening these also, as above, if necessary, a farther supply is produced, to give the tree its first regular form, whether as a Dwarf-standard, or for espaliers, or walls. But as in this article we shall only treat of Dwarf-standards, so for the other sorts of Dwarfs, see ESPALIERS and WALL TREES.

Dwarf standards therefore, are formed at first as above, not trained fan-fashion like espaliers,

espaliers, or wall trees, but promoted to branch out low every way into a circular head, without being trained to any kind of fence, and are therefore properly standards, though of dwarfish stature.

These were formerly in great estimation, and trained in three different ways or shapes, viz. 1. Concave Dwarfs; being trained concave or hollow in the middle, having all the branches ranged circularly around the stem in an ascending direction, so as to form the heart of the tree hollow or concave. 2. Convex or conical Dwarfs, being trained convex or full in the middle, so as to form a close conical head. 3. Horizontal Dwarfs, being trained horizontally, i. e. all the branches trained flat, or in a horizontal position, all around parallel to the surface of the earth; but the concave form is the most eligible; but neither of the methods are at present in much practice, and the mode of training Dwarfs in espaliers, is now almost universally adopted in their stead; which indeed, are every way preferable, both for convenience and bearing; however, a few trees should be admitted in large grounds for variety, and may be disposed singly, one here and there, upon large borders, or on open spaces of grass ground.

They should be no where planted nearer together than twenty feet, particularly the concave and horizontal Dwarfs.

The sorts of fruit trees commonly used for Dwarf-standards, are apples, pears, plums, cherries, and sometimes apricots; but any sort of fruit-trees may be trained in that form, as one direction serves for all.

The method of forming them is, and first of the concave Dwarfs.

To have proper concave Dwarfs, it is necessary to graft them upon Dwarf stocks, as before observed, that they may be moderate shooters, and be of as dwarfish stature as possible; as for example, apples should be grafted upon paradise stocks, and pears upon quince stocks, &c. See STOCKS. And the graft or bud, to be inserted within six or eight inches of the ground; so as the stem may not exceed a foot or fifteen inches in height, and may form branches within that distance of the surface of the earth.

Having therefore grafted or budded them as above, observe, that the first shoots from the graft or bud, are to be stopped or shortened in spring, when a year old, to about five or six inches in length; or to so many eyes or buds, from which to procure from

four at least, to six or eight stout lateral shoots, to give the tree its first regular formation. When these laterals are a year old, and about two feet long, they should be then trained in a horizontal position in different directions on each side of the stem, by means of stakes; at the same time top the end of each shoot, and trim off the lower buds or eyes, to promote a farther supply of three, or more shoots only towards the ends of each of them; and this supply of shoots thus again procured, are, after having one summer's growth, to be trained gradually in an ascending direction, at equal distances all around, so as to form the heart of the tree into a regular concave or hollow; to assist which, and effect a more regular concavity, some wide hoops must be placed within, supported by stakes; and as the branches advance in length, train them up to the hoops, suffering no branch to cross its neighbour, but train them all parallel to each other, six or eight inches distance, in an ascending position as aforesaid; observing, if a farther supply of shoots are still necessary to form the tree all around, at the above distance, then, shortening the last produced shoots must again be practised, either wholly or in part, as shall appear expedient, to force out, in the proper places, the quantity wanted; afterwards train the whole at full length as directed below in their general pruning, and they will then form all along their sides, short thick shoots scarce an inch long, called fruit-spurs, as hereafter mentioned.

As to their general pruning, observe, in the course of that operation, that after the tree is furnished with a proper quantity of branches to form the tree into its proper figure all around, as above-noticed, the shoots or branches are not afterwards to be shortened; observing however, that when necessary to shorten any, either to force out a farther supply of young wood to train up for bearers, or to preserve uniformity, always make the cut on the inside, so as to preserve the uppermost eye, or that immediately next the cut, outward, that the leading shoot may advance in that direction, as hereby the concave form of the tree will be better maintained.

However, the shortening the shoots of these trees should be sparingly practised, particularly apples, pears, plums, and cherries, especially after having obtained branches enough to form the tree all around, at six or eight inches distance, as before observed; for shortening promotes a great superfluity of
strong

strong shoots, and prevents the branches from forming spurs or fruit-buds, i. e. short thick shoots half an inch, or an inch long; for all these sort of trees above specified, mostly produce their fruit upon spurs, see *PYRUS* and *PRUNUS*, which generally first form themselves towards the extremity of the shoots or branches; so that by shortening, you cut away the parts where they would have first appeared, and instead thereof, strong unnecessary wood will shoot forth, and greatly retard the tree in forming for bearing.

Therefore observe the caution, never to practise shortening the branches of these kinds of Dwarf trees, but to promote a supply of more shoots when wanting, as above hinted, or take off cankered parts, or such as are grown much too long, or that grow a-cross the others; and which should be done in the winter pruning, cutting such parts down to the next most suitable shoot, properly situated to supply the place of the part cut away.

No branch must be suffered to grow a-cross another, but when such appears, let it be cut out, or so far retrenched as to preserve due regularity.

All shoots rising in the middle of the tree, that may interfere with the concavity, should be annually taken off close, either in the summer as they are produced, or in the winter pruning. Likewise, after the tree is formed and furnished with a proper quantity of branches all around at equal distances, all shoots arising from the sides of the branches should be also displaced annually, unless any shall appear necessary, to fill any present or apparent future vacancy, or to supply the place of any irregular, or worn-out branch; in which case, leave in the proper places some of the most promising best placed young shoots, training them up between the old branches; observing however, that all shoots evidently superfluous, or unnecessary, should, if possible, be displaced in summer, according as they are produced, which will prove more beneficial both to the form and prosperity of the trees and fruit, than if wholly deferred till the winter; however, do not omit that operation annually, either in summer or winter, at either time cutting off all the above-hinted superfluities quite close, and not leave any stump, as from every eye of which shoots would arise and cause a great confusion of wood.

If the tree produce vigorous shoots at its extremity, it is necessary to leave in summer

some strong lower shoots till winter, to check the luxuriance of these at top, then take them off according to the above rules.

Be careful at each pruning, to observe if there is any appearance of a vacancy, or any very irregular, ill-bearing, or old worn-out branch, or other wood that may want renewing; in which case, leave occasionally some well placed young shoots towards the lower parts, training them up between the older branches to be coming on gradually to a bearing state, to supply the place of bad ones, or any accidental vacancy.

Observe also at each pruning, to preserve with the utmost care all the fruit-spurs, i. e. those short robust shoots of half an inch, or an inch or two long, for it is from these only we are to expect the fruit, which will be evident by observation; but if any of these are become very long, ragged, or stumpy, or crowd others of more eligible growth for bearing, it is proper to thin or regulate them occasionally as you shall see necessary.

The principal pruning seasons are, the summer pruning, which is performed any time in June or July, to clear out all evident superfluous shoots of the year; and the winter pruning is any time from November to March, to clear out also all superfluous shoots omitted in summer; and is also the only proper season to prune out all large branches where necessary, either by being superfluous, irregular, bad bearers, or decayed.

Convex or conical Dwarfs. To form these, they must be grafted or budded low, as directed for the concave Dwarfs, and the first shoots to be also shortened in spring, when a year old; to procure a further supply of several stout lower shoots, to form the first course of branches at about a foot or fifteen inches from the ground; and that, instead of forming the heart of the tree concave, like the former kind of dwarf, train the centre-shoot up the middle for a stem, and suffer it to branch out at every twelve or fifteen inches as it advances in height, training each set of branches a little horizontally.

Thus the tree may be formed into several sets of branches, one above another, which should be so ordered, that the lower-most set be extended the widest, and the next set immediately above it be a little shorter, the next short than that, and so on to the uppermost set, whereby the tree will assume a beautiful conic form; and by observing nearly the same rules of general pruning, as laid down for the

the concave dwarfs, they will produce plenty of fine fruit.

Horizontal Dwarfs.—These are grafted, within from about twelve or eighteen inches, to two feet of the ground, and their first shoots shortened, as for the concave and conical Dwarfs, to promote a regular supply of branches at that distance from the bottom; which, when about a yard long, are to be trained in a horizontal position, suffering no upright to advance in the middle, but train

the whole perfectly flat or horizontal on every side of the stem, continuing them as they advance in length always in the same position, and thus they will spread themselves circularly many feet each way, and produce abundance of fruit.

The same mode of pruning is to be here observed as directed for the concave Dwarfs, so that a repetition here would be superfluous.

E.

EARTH.—Earth may be divided into three classes, sandy, loamy, and clayey.

A good garden Earth may be either of a blackish, hazelly; or chestnut-brown colour neither too light loose and sandy, nor partake too much of loam or clay, but is fattish, light pliant, and easy to work at all seasons; and if three spades deep, it will be still more beneficial for the purpose, though if there be eighteen inches or two feet depth of good staple, it will do for most sorts of esculent plants, and others. as well as for almost all sorts of fruit trees.

Sandy Earth.—All the light, loose, open, and gravelly soils, whether black, grey, hazelly, or yellowish coloured, till the loam or clay is come at, may be deemed of the sandy kind, and is capable of raising some certain plants; but having a mixture of loam or clay, and enriched with dung, it will produce all sorts; for a vegetable planted either in sand alone, or in a fat coherent glebe or Earth alone, receives scarce any growth, but where there is a just mixture of both, the mass becomes fertile.

By means of sand or sandy Earth, strong loam or clay is fertilized, the Earth being thereby rendered porous, and interstices or space maintained, by which the juices are prepared, and thrown off into the roots of the plants, and the fibres find room to extend themselves.

Sandy or gravelly ground easily admits both of heat and moisture, and are apt to

push seeds and plants much earlier in spring than strong loamy or clayey soils.

But sandy land is liable to these inconveniencies, that being sometimes very light and open, it either does not retain a due portion of moisture, or sometimes retains it too long, especially where there is clay at bottom; so in these cases, is apt either to parch or chill too much.

Loamy Earth.—This is that sort of Earth which is a mixture of clay and sand, commonly of a yellowish or hazelly colour, and of a soft, fat, and slippery temperament, not so close a texture as clay, nor too loose and sandy, but of a middle nature between, and is at all times easy to dig and rake, and will readily dissolve by frost and rain.

But some distinguish a true loam, or brick-earth, as that which partakes more of clay than sand.

A good garden loam however should be such a just consistence as is pliable to work, and such as will not stick obstinately to the spade, rake, and fingers, &c. at every flash of rain, nor crust or chap in dry weather.

Loamy Earths, answering the above descriptions, are in many places the most common superficial or top Earth, going frequently one, two, or three spades deep, and is one of the most beneficial soils for almost all sorts of plants and trees. See COMPOSTS and LOAM.

Clayey Earth.—Clay is a strong, cold, heavy, moist Earth, liable to coalesce, and gather into a coherent and compact mass, having but

-it is propagated by seeds sown in autumn

EDGINGS. These are ranges of very small dwarfish over-green plants, as box, A a a thrift,

thrift, &c. closely planted along the edge of borders or beds, serving both for use and ornament.

Edgings are particularly necessary to the edges of such borders or beds as immediately verge walks or alleys of gravel, sand, shells or other loose materials; and are useful to form and preserve a boundary distinction betwixt the borders and walks, and to preserve the earth of the borders from being forced out upon the walks or alleys, and the soil of the walks from the borders; both of which would otherwise be the case, less or more, every time of doing the necessary work, and at every hard shower of rain: Edgings are therefore particularly necessary in flower-gardens, and to the borders immediately verging principal walks, to maintain uniformity and neatness, and, considered as ornamental, that being evergreen, and if planted in a close neat range along the edge of the border, all of an equal width, not more than two inches broad, and one or two high, and always kept within the compass of about three inches in width and height, without gaps and irregularities, but all the way close, and even at sides and top, they have a pretty effect, whether box or thrift, &c. and as some sorts of plants proper to be employed for Edgings, are of the flowery tribe, such as thrift, daisies, pinks, &c. they, besides the property of being evergreen, are very ornamental in their flowers, which, of each sort, are numerous, and continue six weeks or two months in great beauty.

But the best Edging in the world is the dwarf shrubby box. (*Buxus Suffruticosa*,) it being the most effectual, most easily kept in order, and the most durable, retains its leaves and full verdure at all seasons, prospers in all soils and situation, is never hurt by any weather, and will endure many years, always close and regular, with the culture of shearing or clipping once or twice every summer at top and sides. See Buxus.

The next to box for Edgings, is thrift, (*Statice Armeria*), which also grows very close, low, and in verdure all the year; and flowers beautifully two months in summer, but being rather apt to spread soon out of bounds, requires to be reduced, by cutting in considerably on each side, or by replanting it a fresh every two or three years; and its general culture as an Edging is, to trim it a little with garden-shears on each side and top every summer, as soon as done flowering,

cutting off also all the withered flower-stalks, performing it always in moist weather. See STATICE.

Daisies, pinks, catchfly, and several other low herbaceous evergreen flowery perennials are also sometimes employed for Edgings, which have a pretty effect when in flower; but as in one year they spread greatly out of compass as Edgings, should be taken up and replanted every spring or autumn, but more particularly the daisies; and the others, if they stand longer than one year, should be cut in on each side annually after flowering, to preserve uniformity.

Sometimes some sorts of dwarf bushy annuals are sowed for summer Edgings in small gardens, such as the dwarf Virginia stock, hearts-ease, or *viola tricolor*, candy tuft, and several other low bushy annual flowers; but the former of them is the most suitable for an Edging, as it grows low, bushy, and does not ramble, is very flowery, and continues long in bloom.

Several sorts of shrubby aromatics are also used for Edgings, as thyme, savory, hyssop, sage, lavender, and rue, all of which are evergreens, and may be kept low by close shearing; but then they become woody, stubbed, and naked; but these are also sometimes planted as Edgings in kitchen gardens, for oeconomical purposes.

Parsley also forms a good evergreen Edging, for the edges of the quarters and borders of kitchen gardens; and if the true curled sort is sowed, it will be very ornamental, as well as profitable.

As to the method of planting or forming Edgings; if box, the plants are generally planted in small perpendicular trenches, placing them close together, as at once to form a complete Edging. see Buxus. Thrift, daisies, pinks, &c. are commonly planted by dibble, at about two or three inches distance in the line, though, to form a compact Edging at once, they may be planted so close as to touch each other; pink Edgings may also be formed by sowing the seed in a drill along the edge half an inch deep, so suffer the plants to remain. Annual flower Edgings are also formed in the same manner: thyme, savory, and hyssop Edgings may also either be formed by sowing the seed, or by plants or slips; sage and lavender, chiefly by planting young slips; and rue the same, or by seed.

All Edgings, the shrubby kinds in particular, should be neatly thorn or clipped with

with garden-shears, at top and sides every year in summer, and some sorts require it twice in that time, to preserve them perfectly neat, such as box, and most other shrubby kinds.

Never suffer box Edgings to exceed two or three inches in width, nor above three or four high; and thurst and the other herbaceous Edging to get more than three or four inches wide.

Nor suffer the aromatic kinds, if in pleasure-grounds, to exceed five or six inches high, and three or four broad.

For particulars in the different sorts here mentioned, see their respective genera.

ELÆAGNUS, Oleaster or Wild-Olive. It furnishes two ornamental, deciduous shrubs for the shrubbery and stove, garnished with narrow silvery leaves, and small apetalous flowers.

Class and order, *Tetrandria Monogynia*.

Characters.] **CALIX** is monophyllous, bell-shaped, quadrifid, and the inside coloured. **COROLLA**, none. **STAMINA**, four filaments, and oblong incumbent antheræ. **PISTILLUM**, a roundish germen, simple style, and single stigma. **PERICARPIUM**, an oval drupaceous fruit, inclosing an oblong obtuse nut.

The species are,

¹**ELÆAGNUS** *Angustifolia*.

Narrow-leaved Oleaster.] **Elæagnus**, with an upright woody stem, branching twelve or fourteen high; narrow, spear-shaped, shining, fatty leaves, three or four inches long, and scarce half an inch broad; and from the axillæ, small flowers having silvery studded cups, yellow within, succeeded by small olive-shaped fruit.

²**ELÆAGNUS** *Spinosus*.

Thorny elliptic-leaved Oleaster.] **Elæagnus**, with an upright woody stem, branching twelve or fourteen feet high; elliptical, silvery, downy-leaves, two inches long, and near one broad, sharp thorns under each leaf; and small flowers, having the calix yellow within, succeeded by olive-shaped fruit.

Both these trees merit culture, the first for the shrubbery, the second for the stove; their silvery-leaves render them very conspicuous, and effects a delightful variety.

Their propagation is easily effected by layers of their young shoots, also by cuttings, which will be rooted in one year, and may then be transplanted, placing the hardy kinds in the nursery, to have two or three years growth, when they will be fit for the shrubbery.

EPHEDRA, Shrubby Horse-tail.

There is but one species, a low shrubby rushy-leaved evergreen for the shrubbery.

Class and order, *Diœcia Monodelphia*.

Characters.] Male and female flowers on separate plants, the males collected into an amentum; but they rarely flower in England.

The species is;

EPHEDRA *Distachya*.

Shrubby Horse-tail.] **Ephedra** with a low shrubby stalk, branching two feet high, having many swelling joints, sending forth opposite, narrow shoots, branching out into long rushy tufts, opening like leaves, there being no other.

This shrub may be employed in the fronts of small shrubbery clumps; its singularity will encrease the variety.

It is propagated plentifully by suckers or off sets, arising from its creeping roots, which may be transplanted in February or March.

EPILOBIUM, Willow-herb, or French Willow.

This genus furnishes two herbaceous flowery perennials for the full ground, producing annual stalks of three or four feet stature, narrow leaves, and terminated by long spikes of quadripetalous flowers.

Class and order, *Octandria Monogynia*.

Characters.] **CALIX**, four oblong, pointed, coloured leaves. **COROLLA**, four roundish cruciforme petals. **STAMINA**, eight filaments alternately shorter, and compressed antheræ. **PISTILLUM**, a long cylindric germen under the corolla, slender style, and quadrifid revolute stigma. **PERICARPIUM**, a long, cylindric, furrowed, quadrilocular capsule and oblong seeds crowned with down.

The species are.

¹**EPILOBIUM** *Angustifolium*.

Narrow-leaved Epilobium.] **Epilobium** with very creeping perennial roots, upright flower-stems, branching erectly four feet high, long spear-shaped leaves placed irregularly, and all the branches and main stem, terminated by long erect spikes of purple flowers, of very ornamental appearance.

Varieties.] With white flowers,—white purple-striped flowers—with broad leaves and white flowers.

EPILOBIUM *Hirsutum*.

Hairy Epilobium.] **Epilobium** with very creeping perennial roots, upright hairy stalks, branching erectly, three feet high; spear-shaped, sawed, decurrent, hairy leaves placed opposite, and all the branches and main stem terminated by erect spikes of purple flowers.

Both these species of *Epilobium* grow naturally in shady moist places in many parts of Britain, &c. the first are inhabitants of shady woods, the other, the sides of watery ditches, and are great ramblers both by root and stalks; but being ornamental in their mode of flowering, have been long admitted into gardens to encrease the collection of flowery perennials, and are good furniture for large borders, but are peculiarly adapted for shady moist places; they flower abundantly in July and August, continuing a month or six weeks.

They obtained the name of willow-berb from the great resemblance of their leaves to those of the willow.

Both species are propagated in great plenty by their creeping roots, in spring or autumn, which may be divided and planted at once, where they are to remain, and they will flower at their usual season.

EPIMEDIUM, Barrenwort. — It furnishes one low herbaceous flowery perennial.

Class and order, *Tetrandria Monogynia*.

Characters.] CALIX, tetraphyllous and deciduous. COROLLA, four cruciform oval petals, and four large cup-shaped nectariums. STAMINA, four filaments, and bilocular antheræ. PISTILLUM, an oblong germen, short style, and simple stigma. PERICARIUM, an oblong unilocular capsule and many oblong seeds.

The species is,

EPIMEDIUM *Alpinum*.

Alpine Epimedium.] Epimedium with creeping perennial roots, crowned by many stalks eight or nine inches high, dividing at top by threes, each division garnished with heart-shaped stiff folioles, and flower-stalks six inches high, dividing into smaller, each supporting three reddish cruciform flowers in May.

It delights most in shady borders, and may be propagated at pleasure by its creeping roots.

ERYNGIUM, Eryngo, or Sea Holly.

This genus comprises several hardy, herbaceous, flowery perennials, producing erect stalks, from one to three feet high; simple, entire, and divided prickly leaves; and the stalks terminated by roundish aggregate heads of quinquepetalous flowers.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, a conical receptacle, common to many florets, having a five-leaved general involucre, and each floret a pentaphyllous calix coloured above. COROLLA, each floret is of five inflexed petals, collected into a roundish uniform head. STAMINA,

five filaments and oblong antheræ. PISTILLUM, hairy germen, two styles, and simple stigmas. PERICARIUM, an oval two-parted fruit to each floret, having each one taper seed.

The principal species are:

ERYNGIUM *Maritimum*.

Maritime Eryngo, or Sea Holly.] Eryngium with creeping, penetrating, fleshy, perennial roots crowned by roundish, plaited, stiff, spinous-edged leaves, and between them upright stalks a foot high, garnished with small roundish leaves, and terminated by roundish heads of whitish blue flowers.

ERYNGIUM *Amethystinum*.

Amethystine-coloured Eryngo.] Eryngium, with perennial roots, crowned with trifid, hand-shaped, many-pointed leaves, somewhat pinnated at the base; upright stalks two feet high, garnished with many-parted spinous-leaves, and terminated at top by roundish-heads of amethystine or purple violet-coloured flowers.

Variety.] With pale amethystine heads of flowers.

ERYNGIUM *Planum*.

Plane leaved Eryngo.] Eryngium with downright perennial roots, crowned with oval plane leaves, crenated on the edges, upright blue stalks two or three feet high, garnished with many-pointed spinous leaves, and terminated at top by oval heads of amethystine blue flowers.

Variety.] With stalks white upward, and white heads of flowers.

ERYNGIUM *Alpinum*.

Alpine Eryngo.] Eryngium with perennial roots, crowned with oblong heart-shaped leaves, upright stalks branching each way two or three feet high, adorned with deeply divided, many-pointed leaves, all ending in spines, and all the branches and main stalk terminated by conical light blue heads.

ERYNGIUM *Aquaticum*.

Aquatic American Eryngo.] Eryngium with perennial roots, crowned with long sword-shaped, stiff, sawed, spinous leaves a foot long, and between them an upright stalk two feet high, terminated by oval, whitish-blue, heads of flowers.

All these species of *Eryngium* are hardy perennials, the root durable, but annual in stalk; the first of which is a maritime plant, growing naturally on the sea shores in many parts of Britain, &c. the second, third, and fourth inhabit mountainous places of the continent.

finent, and the fifth is of America; all of which are retained in curious gardens, as plants of singularity and ornament.

The flowers of all the sorts are collected into close roundish heads at the top of the stalks, each head composed of many florets. See the *Characters*.

They all flower principally in July, and the seeds ripen in September.

All the sorts succeed in any of the borders, or other compartments, though the first sort is the most prosperous in gravelly or sandy soils.

They are propagated by seeds, sowed either in autumn or spring, in a bed or border, and raked in, the autumn sowing generally comes up strongest in spring following; and in autumn after transplant the plants into the places where they are to remain to flower.

ERYTHRINA, coral-tree (*Corallodendron*.)

This genera consists of shrubby, flowery, exotics for the stove, adorned chiefly with trifoliate, or three-lobed leaves, and scarlet spikes of papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX** is monophyllous, tubular, and entire. **COROLLA**, is papilionaceous, and of five petals, the standard spear-shaped and very long; the wings oval and short; and the keel dipetalous. **STAMINA**, ten diadelphous filaments, and arrow-headed antheræ. **PISTILLUM**, a pediculated subulate germen, and style, and simple stigma. **PERICARPIUM**, a long swelling, unilocular pod, and kidney-shaped seeds.

The principal species:

¹**ERYTHRINA** *Corallodendrum*.

Corallodendron, or Smooth Coral-tree.] Erythrina with a tree-like woody stem, branching irregularly ten or twelve feet high, smooth trifoliate leaves, having heart-shaped lobes, and from the ends of the branches short thick spikes of beautiful scarlet flowers.

²**ERYTHRINA** *spinosa*.

Spinous Coral-tree.] Erythrina, with a tree-like woody stem, branching ten or twelve feet high, armed with spines, trifoliate prickly leaves, and red spikes of flowers.

³**ERYTHRINA** *pieta*.

Black thorned Coral-tree.] Erythrina with shrubby stalks, dividing into branches, five or six feet high, strongly armed with black spines; trifoliate small leaves, and pale scarlet spikes of flowers.

⁴**ERYTHRINA** *herbacea*.

Herbaceous Erythrina.] Erythrina with a thick woody root, sending up herbaceous stalks annually in spring, two feet high, garnished

below with trifoliate narrow-pointed leaves, and terminated by long scarlet spikes.

All these plants being natives of hot countries, in Africa and America require the constant shelter of a stove in England, so must always be kept in pots, and retained in that department.

They flower here in our stoves, in summer are extremely beautiful, but are not succeeded by seeds in this country.

All the sorts are propagated by seed, which are annually imported hither from Africa and America. Sow them half an inch deep in pots of light rich earth, which plunge in the bark-bed of the stove, &c. and when the plants are two inches high, prick them in separate small pots, plunging them also in the bark-bed; give frequent waterings, and as they encrease in growth shift them into larger pots.

ERYTHRONIUM, Dog's Tooth.

(*Dens Canis*.) or Dog's Tooth Violet.

The plants are low, herbaceous, flowery perennials for the full ground, rising four or five inches high, terminated by hexapetalous flowers.

Class and order, *Hexandria Monogynia*.

Characters.] **CALIX**, none. **COROLLA**, six oblong petals, reflexed and spread open to their base. **STAMINA**, six short filaments and oblong antheræ. **PISTILLUM**, a turbinate germen, simple style, and triple stigma. **PERICARPIUM**, a sub-globose trilobular capsule, and many oval flat seeds.

There is but one species, which however, admits of several varieties, all of the flowery tribe.

The species is,

ERYTHRONIUM *Dens Canis*.

Dog's Tooth, (*Dens Canis*.) Erythronium with oblong, tooth-shaped, fleshy, white perennial roots, crowned by two oval, purple and white spotted leaves, united at their base, and between them, an upright naked purple stalk, four inches high, terminated by one drooping flower, having six spear-shaped reflexed petals, of different colours in the varieties.

Varieties are.] Dog's Tooth with white flowers—with purple flowers—with pale red flowers—dark red flowers—crimson flowers—yellow flowers, but rare—and dog's tooth with narrow leaves and flowers of the above colours.

All these varieties are hardy, durable in root, but annual in leaf and stalk, which rise early in spring, and flower in April, but rarely furnish good seeds in England; they may be all employed to adorn the fronts of borders,

borders, planting them in small patches, in which they will make a good appearance.

Their propagation is by off-fets from the roots, when their leaves decay, from June till September.

ESPALIERS, ranges of dwarf fruit trees, trained to a trillage of wood-work in such order as to form a kind of hedge.

Espaliers are commonly arranged in a single row round the boundaries of the quarters or principal divisions of the kitchen garden, there serving a double or treble purpose, both profitable, useful, and ornamental; they produce plentifully of large fine fruit, without taking up much room, or any ways incommoding the ground, and being in a close range, hedge-like, they wonderfully shelter the esculent crops in the quarters; and having borders immediately under them on each side, afford different aspects for different plants, as they shall require at different seasons of the year; as in the winter for shelter; the spring for forwardness; and the summer for shade; and as to the ornament and variety, what can be more delightful in spring, in the excursion of the walks, than the charming appearance the trees make when covered with their snowy bloom, differing in themselves, in those of different genera, species, and varieties; in summer, to see the fruit of the different sorts advancing gradually to perfection; and in autumn, how pleasing to find the various kinds arrive successively at maturity: and as the trees are arranged all of an equal height, not exceeding six or seven feet, closely furnished with branches ranged at regular distances one above another, from the very ground upward, the fruit hereby exhibits itself to great advantage, and being low, and the branches fixed, is not liable to be blown down by wind.

An Espalier has this advantage over a wall tree, that it has liberty to form branches or fruit spurs on both sides, which in the wall-tree cannot be effected but on one.

The sorts of fruit usually employed to form Espaliers, are principally apples, pears, and plums; but several other sorts may also be used to encrease the varieties, as quinces, apricots, cherries, almonds, mulberries, vines, figs, filberds, &c.

Observe always however, to contrive all those trees in the same line or range, that are nearly of the same growth, for the sake of uniformity.

They should be planted principally on those borders serving as the immediate outer bound-

dary to the quarters of the kitchen garden, and immediately verging the principal walks; they may also be planted in pleasure grounds, &c. if thought convenient. The width of the borders may be about six feet, and the line of Espaliers placed four feet at least, from the outer edge, and eighteen or twenty distant in the row, especially for apples, pears, and plums, though twenty five feet is not too much; but the trees planted at that distance, taking a long time before they approach each other to fill the Espalier, they appear straggling and irregular, that few persons plant them more than eighteen or twenty feet asunder; if however they are planted only fifteen or eighteen feet distance, they will meet and form a close Espalier sooner by some years, and when they begin to interfere and incommodate each other, the interfering branches of every other tree may be gradually cut away annually in winter-pruning, to give the intermediate trees room to advance and meet each other, and at last the others may be taken quite away, and the remaining trees standing at thirty or six and thirty feet distance will have full scope to spread.

Their general training and planting.

All trees intended for Espaliers, that are propagated by grafting and budding, should be grafted or budded within six inches of the ground, to procure lower branches to furnish the Espalier, quite from the bottom regularly upward; and the first shoots from the graft or bud, should also in spring, when a year old, be headed down within five or six inches of the graft, to force out a supply of five, six or more good shoots at that part, for the reason just mentioned; and whether the trees are then in the nursery or planted in the Espalier, its shoots or branches so obtained, should, the same summer or autumn, when eighteen inches or two feet or more long, be trained along as they advance to stakes placed for that purpose, laying the shoots to the right and left horizontally in the position proper to give them the first necessary form as Espalier-trees; if the trees are raised in nurseries for sale, the above practice is eligible, whereby the trees are rendered more saleable, and their value encreased; and if the first heading does not furnish the supply of lower branches required, you may practise a second heading, either in whole, or only some of the middlemost shoots, as you shall judge necessary; afterwards they must be trained all principally at full length.

When the trees in the nursery are from two to

to four or five years old from the grafting or budding, being furnished with six, eight, ten, or more good branches near the bottom, properly situated for ranging two ways, according to the line of the Espalier, they are then fit for planting out finally for that purpose, observing the distances as before-mentioned. If apples and pears upon dwarf stocks, fifteen or eighteen feet may be sufficient; but if upon free stocks, twenty-one feet at least is necessary: plums should also be planted eighteen feet distance at least, in the line; cherries, apricots, figs, mulberries, vines, &c. never less than fifteen distance, but if eighteen the better: as soon as they are planted, place stakes, ranging the way of the row, and to which tie the branches with osier twigs, those of each tree horizontally to the right and left, keeping an equal number on each side, at six or eight inches distance one above another, and at full length; except a farther supply of more branches may be wanting, to furnish the bottom and middle of the tree, then shortening is to be practised according to the rules afore-mentioned, to obtain the proper supply; afterwards train all the branches at full length, till all those of each tree meet, and all redundant shoots more than the allotted horizontals are to be displaced.

Another method of forming Espaliers, sometimes practised, is, after having headed down the first shoots, as above ordered, and suppose the trees in consequence furnishes about three bottom shoots, the two side ones are trained horizontally, the way of the Espaliers, and the middle one is trained upright; if five shoots, two must go to each side, and the middle one perpendicular: this perpendicular shoot must still be directed upwards, to furnish more lateral shoots for horizontals, which must be trained horizontally to each side, as above, still continuing your upright in the middle; observing however, if the upright shoot should not throw out horizontals low enough, it should be shortened, whereby it will furnish fresh shoots at any desired height, two or four of which, according to the number produced, are to be used for horizontals, and one still directed up the middle for a stem, and so continue encreasing your number of horizontals annually, ranging from each side of the stem, at six or eight inches one above another, from bottom to top of the Espalier.

In planting Espaliers, in respect to the treillage for training the branches upon, you may either only place four or six common

stakes to each tree, in a line, just to train the branches the first two or three years, till the trees are somewhat advanced; then taking these away, form a regular treillage-work, as directed below; or if you are anxious to preserve uniformity, a general treillage may be formed at once, at first planting of the trees.

These treillage-works for the above purpose, may be of different degrees of taste for use and ornament, according to your fancy or convenience: the cheapest and the soonest made, is that of straight stakes driven into the ground a foot distance, and sawed level at top, five or six feet high; and slips of deal, or poles arranged along the top the whole length, and so train the branches of the trees along, from stake to stake.

But for the sake of ornament, a regular frame or treillage may be formed of square timbers, and to have it more durable, the principal posts might be of oak, two or three inches square, and rails carried from post to post, the first about eighteen inches from the bottom, one at top, and a third in the middle space; then thin square slips of lath, or small ashen poles, or the like, are fixed upright to the rails on the side next the trees, a foot asunder, and paint the whole with oil-colour, to render it more ornamental and durable.

To either of the above treillage-work, the Espalier-trees are to be trained in a regular manner, bringing the lowermost branches down horizontally within eight or ten inches of the ground, tying them to the uprights of the treillage; the next course six or eight inches above these, in the same position; the same of the next and every succeeding course all the way up, preserving an equal number on each side, ranging exactly in the same horizontal position, and distance from bottom to top, training them always along at full length, except, as aforesaid, there be a want of wood in any part; then, to force out the supply wanted, shorten some contiguous shoots to five or six inches, either the same summer it is produced, in June, otherwise not till spring following, and so continue every year encreasing the number of horizontals, and place them properly till the trees are furnished with branches one above another, from bottom to top of the treillage.

Their general pruning.

As to the general pruning of Espalier-trees, observe for one thing, the branches are for the general part to be trained always at full length, for shortening more than just necessary.

necessary to procure an occasional supply of wood, would not only produce a confusion of branches, but as the trees always produce their fruit upon spurs, as observed in the article DWARF TREES, which, if the branches are trained at full length, generally first form themselves toward the upper part, and gradually along the sides at each eye; that by shortening, it would cut away the said first fruitful parts, and from the lower eyes, that instead of forming spurs, force out strong unnecessary wood, and scarce any fruit; and this is the reason we see so many ill-formed Espalier-trees, many people thinking shortening the shoots is necessary to strengthen them as they call it, and hereby the tree throws out vast quantities of wood every summer, which they either then, or in winter, or spring pruning, cut out, generally leaving a stump of each shoot about an inch or two long, and from every eye of these stumps, more strong shoots rise the year following, and these are also stumped off in the same manner, and so they continue from year to year, by which means the tree is filled with large clustering ragged spurs, formed entirely of the stumps of shoots: therefore, always keeping in mind to continue all the shoots and branches principally at full length; and when necessary, to cut out any superabundant wood, always take it off quite close, never leaving any stump, and constantly encourage the fruit spurs, which are natural shoots of from about half an inch to one or two in length; observing however, when any of these are worn out, or grown cankerly, or become very long, as to project considerably foreright, they should be cut out close, to make room for those of better growth.

Espaliers should have two principal dressings annually, i. e. summer and winter pruning.

In summer the trees often produce numbers of shoots more than are wanted, or that can be trained in; therefore, keeping in mind the proper distances and general position of the necessary branches to form each tree, begin early in June, and clear off all superfluities, as they are produced, that is, all fore-right shoots issuing from the front and back of the branches; and those of very luxuriant growth, should always be displaced, rubbing or cutting them off close; not however reducing any of those shoots produced immediately from the end of the branches, which must be left entire, to extend the branch in length, and

form a further supply of fruit-spurs. All other shoots, however good and well placed, arising from the sides of the horizontals, and that are evidently superabundant, i. e. more than what can be trained in, consistent with the allotted distances, and regular position of the general horizontals or bearing-branches, should also be taken off; observing however, to preserve here and there a good shoot towards the lower part of the branches, in the most vacant spaces, or where bad branches occur, training them up between at full length till winter pruning; and if then not wanted, may be cut out: for it is necessary always, at any rate, to leave some as a reserve till winter, in case of any unforeseen vacancy happening. In the above manner go over the Espalier-trees of all sorts twice every summer at least, the first time early in June as aforesaid, and again in July. In the first dressing in June, which if there are any vacancy want filling, you may pinch any contiguous strong young shoot of the year, to three or four eyes, whereby it will furnish the like number of shoots the same season, which you may train into the vacant space.

The above summer dressings are not only beneficial to the trees, but, clearing out useless wood, admits the sun and air to effect the growth and ripening of the fruit.

In performing the summer dressings, if you begin betimes, before the young wood becomes long and woody, all redundances may be rubbed off close by hand; but if the shoots are first suffered to be of considerable length, and hardened, the knife must be used, always rubbing or cutting close.

Winter pruning. This may be performed any time from the fall of the leaf in November till March; in this pruning, a general regulation is to be observed both to old and new branches when necessary, therefore examine first the state of all the main horizontals, if any are decayed, or much cankered, take them out, either to their origin, or to some healthful young branch arising from them below the defect; likewise any old naked branch, not furnished with bearing spurs, nor support-branches, that are, should also be cut out, where there are large clustering ragged spurs, formed by the remaining stumps of shortened shoots as before observed; cut them also off close, being careful to preserve all the natural fruit spurs already described. Examine also such young shoots that were trained up in the summer dressing, such of them that are

are well placed, and towards the lower parts of the main branches, and are likely to be wanted to fill any present or future vacancy, are to be left and trained up regularly at full length; for it is necessary always to have some young branches in training between the principal ones, in different parts, where you shall judge necessary, without crowding, to be coming forward gradually to a bearing state, to supply the place of such as are apparently in a decaying state, or but bad bearers; all other young shoots left in summer, that are not wanted for the above purpose, should now be cut out close, observing, as in the summer pruning, that all shoots arising singly, immediately from the ends of the horizontals, must now also be left entire, that is, leaving only one to each branch as a leader, and to extend the respective branches in length, to fill the extent of Espalier allotted; so that every branch and shoot so reserved for training in, must, except in case of a vacancy, also still be continued along at full length, they will then naturally form fruit-spurs at almost every eye or bud all along their sides.

For the branches of apples, pears, plums, cherries, &c. always produce their fruit upon spurs, which generally begin to form when the branches are two or three year old, provided the branches are left entire, but if shortened, they never form properly.

Having winter-pruned the trees, you must then proceed to fresh tie all the horizontals, old and new, in a neat manner to the treillage, still preserving nearly an equal number on each side of every tree, and all at regular distances of six or eight inches, and their position so much horizontal, as their extremities may not be above six or eight inches higher than the bottom parts, training every branch as straight as an arrow, clean from the bottom to the extremity, tying them neatly to each upright of the treillage.

The best material for tying the branches of Espaliers, is osier, chusing the small twigs of about eighteen inches, or two feet long, which, if you have none of your own growing, may purchase them cheap enough at the basket-makers, the yellow osier is the best if it can be obtained. See SALIX.

The mode of tying is, put the twig around behind the treillage, keeping the biggest end fast, bring the other end round the branch, to meet it, twisting it about the big end once or twice, close to the branch, and turn the point in betwixt that and the tying, draw it

tight, then cut both ends even, to about an inch; in this manner every branch must be tied to all the uprights of the treillage its length reaches.

EVER-GREENS, (*Sempervirens.*)

All sorts of trees, shrubs, and herbaceous plants that retain their green leaves the year round, may be denominated Ever-greens, though it is most commonly understood of trees and shrubs, of which there are great numbers in our gardens and plantations, employed both for ornament, variety, and as forest trees for timber, many of which are adapted to grow in any part of the habitable world, and in general their leaves are harder and less succulent than those of deciduous trees; they are not in the least influenced by the clemency or inclemency of seasons, but preserve them in constant verdure through the year; the old leaves remaining a long time after the formation of the new ones, and do not drop them at any determinate time.

Many herbaceous perennials enjoy the same privilege with the Ever-green trees in retaining their leaves, and resist the severities of winter; some even can dispense with earth for some considerable time, such are the house-leeks, navel-worts, aloes, &c. being replete with juices, which the leaves imbibe from the humidity of the atmosphere, sufficient for effecting the purposes of vegetation.

Notwithstanding all the principal Ever-green trees and shrubs are fully treated of, as they occur in the course of this work, we think it eligible to collect into one point of view, a list of all the principal sorts commonly cultivated in the nurseries for sale, and which are proper for use and ornament in gardening.

In this place however we shall only exhibit the hardy sorts; for the others, see GREEN-HOUSE, HOT-HOUSE, &c.

Each sort is arranged according to its *generic* title, viz.

ARBUTUS, or strawberry-tree—common Arbutus, with oblong fruit—with round fruit—with red flowers—double blossom common Arbutus—oriental Arbutus, or andrachne—curled-leaved andrachne.

ARTEMISIA, Mugwort—tree wormwood.

ATRIPLEX, see purslane-tree,—broad-leaved—narrow-leaved.

BUPLEURUM, shrubby Æthiopian hartwort.

BUXUS, the box-tree—broad-leaved tree box—narrow-leaved—gold-striped—silver-striped—gold-edged—curled-leaved striped—dwarf shrubby box.

B b b

CELASTRUS,

CELASTRUS, staff-tree—Virginia upright celastrus—climbing celastrus.

CISTUS, rock-rose—poplar-leaved—willow-leaved—bay-leaved—waved-leaved—round-leaved—sea purslane-leaved—oblong white-leaved—hoary-leaved—Montpelier white gum cistus—ladaniferous cistus—Cretan cistus.

CLEMATIS, virgins bower—Ever-green Spanish climber.

CNEORUM, widow-wail, but one sort.

CUPRESSUS, cypress-tree—common cypress, with upright branches—with spreading branches—with small fruit—blue-berried cypresses.

CYTISUS, tree trefoil—Ever-green Neapolitan cytusus.

DAPHNE, spurge-laurel—common spurge-laurel—variegated spurge-laurel.

EPHEDRA shrubby horse tail, but one sort.

EUONYMUS, spindle tree—Ever green spindle-tree.

HEDERA, ivy-tree—common ivy-tree—yellow-berried—gold-striped—and silver-striped common ivy.

ILEX, the holly-tree—common; of which there are the following varieties—Common green prickly-leaved—smooth green-leaved—green-leaved yellow-berried—box-leaved—gold-striped common prickly-leaved—silver-striped common prickly-leaved—gold-striped smooth-leaved—silver-striped smooth-leaved—narrow-leaved striped—cream-coloured striped fawed-leaved—hedge-hog-leaved, having the whole surface covered with short spines, of which there are, green hedge hog—silver-striped hedge-hog—gold-striped hedge-hog—and silver-edged hedge-hog—blotched-leaved yellow-berried—Hertfordshire white-leaved—copper-coloured; with several other less material varieties—Dahoon broad-leaved holly.

JUNIPERUS, Juniper tree—common juniper—taller Swedish common juniper—Spanish large-berried juniper—red Virginia and Carolina cedar—Bermudas cedar—Phœnician cedar—Lycian cedar—great cypress-leaved Jamaica cedar. Savins, spreading favin—upright favin—striped favin: all the above are species and varieties of *Juniperus*.

KALMIA, broad-leaved—narrow-leaved.

LAURUS, bay-tree—common bay—broad-leaved—narrow-leaved.

LIGUSTRUM, privet—Ever-green privet.

PHLOMUS, Jerusalem sage-tree—broad-leaved yellow phlomis—narrow-leaved yellow phlomis—purple phlomis, or Portugal sage-tree.

PINUS, pine-tree, fir-tree, and cedar of Lebanon:—pine kinds are, wild pine, called Scotch fir—pineaster, or long-leaved wild pine—Weymouth pine—great-coned stone pine—long three-leaved swamp pine—cembro pine—frankincense large-coned pine—dwarf pine:—fir kinds are, silver yew-leaved fir—Norway spruce fir—Newfoundland white spruce fir—Newfoundland black spruce fir—Newfoundland red spruce fir—hemlock fir—long-coned Cornish fir—balm of Gilead, or sweet-scented fir—oriental fir—cedar of Lebanon.

LONICERA, honey-suckle—Ever-green honey suckle.

MAGNOLIA, Ever-green magnolia, called laurel-leaved tulip-tree.

MEDICAGO, moon trefoil—shrubby, hoary, Ever-green medicago.

MESPILUS, the medlar—Evergreen mespilus, pyracantha, or Ever-green thorn.

PHILLYRIA, mock privet—the common, oval-leaved, privet-leaved, and olive-leaved—the broad-leaved, with smooth leaves, prickly-leaved, and sawed-leaved—the narrow-leaved, with rosemary-leaves, lavender-leaved, and striped-leaved.

PRINOS, winter berry—Ever-green winter berry, Yapon, or South-sea thea, formerly *Cassine*.

PRUNUS, plum-tree—Ever-green prunus, or laurel-tree; of which are, common green laurel—gold-striped laurel—and silver-striped laurel—Portugal laurel.

PYRUS, pear-tree—Ever-green sweet-scented Virginia crab-tree.

QUERCUS, oak-tree, and cork-tree—common Ever-green oak, with broad leaves, narrow leaves, and holly-leaved—cork-tree with broad leaves, and narrow leaved—dwarf kermes oak—live oak.

RHAMNUS, including alaternus and buckthorn—common alaternus—broad-leaved alaternus—jagged-leaved alaternus—blotched-leaved alaternus—gold striped-leaved alaternus—silver-striped alaternus—Ever-green buckthorn with narrow leaves—olive-leaved.

RHODODENDRON, dwarf rose bay.—The common dwarf-rose bay—large American.

ROSA, rose-tree—Ever-green rose.

RUSCUS, butchers broom—common myrtle-leaved, prickly butchers broom—broad-leaved hypoglossum, or tongue-upon-tongue laurel, Alexandrian laurel.

SALSOLA, stone-crop-tree, formerly *Che-nopodium*.

TAXUS

TAXUS yew-tree—common yew-tree—short-leaved—variegated-leaved.

THUYA, *Arbor Vitæ*, or tree of life—common arbor vitæ—Chinese arbor vitæ—American sweet-scented—variegated.

VIBURNUM, *Laurustinus*—common laurustinus—broad-leaved—hairy-leaved—shining-leaved—white-striped-leaved—yellow-striped-leaved.

ULEX, furze, gorse, or whins—common wild furze—white-flowered—long narrow-spined—short-spined—large French furze—dwarf-furze.

All the above list of Ever-green trees and shrubs, are so hardy, that they prosper in almost any common soil and situation: several of the large sorts may be employed both as forest trees, and for ornament, and the sorts in general are choice furniture for all kinds of shrubbery works, which, for the general part should be stationed in clumps or plantations by themselves, and not too generally intermixed with trees of the deciduous tribe, except here and there one towards the fronts of clumps, and borders of principal plantations, where they may be conspicuous; but they have a fine effect when they are stationed in clumps alternately with those of the deciduous kinds, either on the boundaries of grand lawns, or any other principal part of pleasure-grounds, parks, or fields, or sides of hills, &c.

These plants, both of the tree and shrub kind, in all plantations, whether in small or large clumps, or in any running shrubbery works, should all be suffered to retain their natural growth, only just to cut out or shorten any very rambling or irregular shoot or branch, and broken and decayed wood.

Formerly hedges of Ever greens were in great estimation for purposes of ornament, but the prevailing taste of rural designs in gardening has almost abolished every thing of that kind from the English gardens; Ever-greens were also in great repute for effecting various pieces of rural architecture, both in hedges and other works, forming cabinets, pavillions, porticoes, pilasters, niches, arcades, cornices, pediments, amphitheatres, and various other figures, which in ancient gardening were often so arranged, and curiously trained, as to effect an air of grandeur and art, but becoming at last too general, and so predominant, that scarce any thing else was to be seen, the taste created disgust, and is now almost universally supplanted by the introduction of designs entirely rural; though,

for the sake of variety, something of these regular works might still be admitted with propriety in some particular parts of large pleasure-grounds, which, if judiciously disposed, not to obstruct views, &c. they may be useful both to effect variety and ornament, in contrast with rural designs, as well as afford an opportunity for the gardener to display his ingenuity in such kind of works.

The sorts of Ever-greens commonly used for the above kind of work in hedges, &c. are yew, holly, phillyrea, alaternus, laurustinus, and Ever-green oak; sometimes laurel, bay, tree-box, pyracantha, sea purslane shrub, juniper, Virginia cedar, and rosemary; but yew and holly are superior for any general work, they growing very close and firm, and always retain their position, though, several of the other sorts appear very beautiful in any kind of hedge-work, particularly the phillyrea, alaternus, laurustinus, Ever-green oak, and laurel; but for single detached figures, yew is the best calculated, sometimes holly, and the tree-box is also used for that purpose.

All hedge-work and figures of any of the above kind, should always be clipped once every summer at least; but, to have them perfectly neat, should have that operation performed twice, the first in June, and the second in August. See **HEDGES**.

EUONYMUS, Spindle tree.

This genus furnishes two hardy deciduous and ever-green flowering shrubs for the shrubbery, of ten or twelve feet stature, ornamented with simple leaves, and bunches of small pentapetalous white flowers.

Class and order, *Pentandria Monogynia*.

Characters.] **CALIX** is monophyllous, and five-parted. **COROLLA** four or five oval, plane spreading petals. **STAMINA**, five short filaments, and twin antheræ. **PISTILLUM**, an acuminate germen, short style, and obtuse stigma. **PERICARPIUM**, a succulent pentagonous, quinquangular, quinquelocular, coloured capsule, having one oval seed in each cell.

There are but two real species, viz.

EUNONYMUS *Europæus*.

European deciduous Spindle tree.] **Euonymus** with an upright woody stem, dividing into many branches, rising ten or fifteen feet high, garnished with oblong opposite leaves; and from the sides of the branches, small bunches of greenish quadrifid flowers, succeeded by pentagonous capsules, disclosing their seeds in a beautiful manner in autumn.

Varieties.] Narrow leaves and deep red berries—with pale red berries—with white berries—with broad leaves—with variegated leaves.

²*EUONYMUS Americanus.*

American Ever-green Spindle-tree.] *Euonymus* with a shrubby stem, dividing into many opposite branches, rising six or eight feet high; garnished with spear-shaped ever-green leaves, growing opposite, and from the sides and ends of the branches; small clusters of quinquifid whitish flowers, succeeded by roundish, rough, protuberant capsules, seldom ripening seeds in England.

Variety.] With variegated leaves.

Both these species and varieties are hardy, and succeed in any common soil and exposure.

The first grows wild in hedges and woods in many parts of Britain, and other parts of Europe; but has been long an inhabitant of gardens, esteemed for the ornamental appearance of its seeds, particularly the red sorts, in October and November, when the capsules spread open, and expose the berry-like seeds, form a fine variety, the branches of which being used for making skewers and spindles, derives the name spindle-tree.

The second is of American growth, and is a very pretty ever-green, for any ornamental plantation.

Propagation of both Species.

The *Euonymus Europæus*, and varieties, may be propagated plentifully by seeds, layers, and cuttings.

By Seed—Sow it in a bed or border of common earth, in October or November, covering with earth near an inch deep, and the plants will rise in spring following, though sometimes many of them not till the second spring; keep them clear of weeds till autumn, then transplant them in nursery-rows, and in two or three years they will be of due size for the shrubbery.

By Layers—Lay down the young shoots in autumn, or winter, or early in spring, giving them a slit at a joint, and they will be rooted by autumn following.

By Cuttings—In autumn take off cuttings of the young shoots eight or ten inches long, plant them in a shady border, and they will be rooted in one year.

Either of the two latter methods, or budding, or grafting, are the only certain way of continuing the varieties, which vary from one to the other by seed.

The second sort, and variety, is propagated chiefly by layers of the young branches in autumn, giving each a slit, and they will be rooted and fit to transplant by that time twelvemonth.

EUPATORIUM, Hemp Agrimony.

Of this genus, are several herbaceous flowery perennials for the pleasure-ground, producing annual stalks from two to four or five feet high, adorned chiefly with simple leaves, and terminated by clusters of compound flowers.

Class and order, *Syngenesia Polygamia Æqualis*.

Characters.] *CALIX*, a scaly, imbricated general cup. *COROLLA*, several funnel-shaped hermaphrodite florets, five-parted, and spreading at the brim. *STAMINA*, five filaments, and cylindric antheræ. *PISTILLUM*, a small germen, long bifid style, and narrow stigma. *PERICARPIUM*, none. *SEMEN*, an oblong downy seed under each floret.

¹*EUPATORIUM Cannabinum.*

Common European Hemp Agrimony] *Eupatorium* with upright reddish stalks, three feet high, fingered-leaves, having oblong indented lobes, and the stalks terminated by large cluster of pale red flowers.

²*EUPATORIUM Maculatum.*

Spotted-stalked American Eupatorium.] *Eupatorium* with upright dark purple-spotted stalks two feet high, garnished with spear-shaped, equally serrated, rough leaves by fives, and the top terminated by a corymbus cluster of purplish flowers.

³*EUPATORIUM Aromaticum.*

Aromatic White Pennsylvanian Eupatorium.] *Eupatorium* with upright stalks three feet high, oval obtuse, trinervous, serrated leaves, and the stalks terminated by corymbus clusters of white flowers.

⁴*EUPATORIUM Purpureum.*

Purple-stalked Canada Eupatorium] *Eupatorium* with upright stalks four feet high, garnished with long, spear-shaped, unequally serrated, rough leaves by fours, and terminated at top by clusters of purple flowers.

⁵*EUPATORIUM Altissimum.*

Tall, long-leaved Pennsylvanian Eupatorium.] *Eupatorium* with upright ligneous stalks, four or five feet high, garnished with very long, spear-shaped, nervous, slightly sawed leaves, and terminated at top by corymbus clusters of white flowers.

⁶*EUPATORIUM perfoliatum.*

Perfoliate Virginia Eupatorium.] *Eupatorium* with upright stalks three feet high, garnished

nished with long rough leaves, connected at their base and perforated by the stalk, which is terminated by clusters of white flowers.

All these plants have perennial roots, and annual stalks rising in spring, flower in July and August, and produce ripe seed in autumn; the first grows wild in England, by water-sides, but all the others are of American growth, and they are very hardy.

They are proper furniture for the compartments of large pleasure-grounds, to encrease the variety of flowery perennials, and will succeed any where, but delight most in moist shady places.

Their propagation is by seed, and by parting the roots in autumn or spring.

Sow the seed on a bed or border of common earth, either on the surface and raked in, or in shallow drills half an inch deep; and when the plants are two or three inches high, prick some of them out five or six inches apart, to stand till autumn, then transplant them where they are to remain.

By parting the roots.—The roots furnish off-sets plentifully, which may be separated in autumn, and planted out separately, either into nursery-beds for a season, or at once in the places where they are to stand.

Their principal culture is, the keeping clean from weeds, digging about them annually, and cutting down the decayed stalks in autumn.

EUPHORBIA, burning thorny plant, including also *Tithymalus* (*Euphorbia*.)

This genus comprises many shrubby and herbaceous succulents, mostly tender exotics, for the stove and green-house; consisting chiefly of thick, fleshy, succulent stalks and branches, frequently armed with thorns, obtaining in stature some ten or twelve feet, others scarce so many inches, of various singular growths, often entirely devoid of leaves, and with quadripetalous close-fitting flowers.

Class and order, *Dodecandria Trigynia*.

Characters.] **CALIX** is monophyllous ventricose, four or five-parted, and persistent. **COROLLA**, four or five thick truncated petals. **STAMINA**, twelve or more filaments, and globular didymous antheræ. **PISTILLUM**, a roundish trigonous germen, three styles, and obtuse stigmas. **PERICARPIUM**, a roundish trilocular capsule, and three roundish seeds.

The species chiefly cultivated in the English gardens, are.

¹**EUPHORBIA Antiquorum.**

Euphorbia of the Ancients.] Euphorbia, with an

upright, triangular, succulent, perennial stalk, rising six or eight feet high, armed with crooked spines, and emitting on every side, many triangular irregular spreading branches, having at their extremities roundish leaves, that soon drop off, and sometimes a few whitish flowers.

Variety.] With upright, three and four-angled, jointed, very thorny stalks, and erect branches.—(*Trigonum*.)

²**EUPHORBIA Neriifolia.**

Oleander-leaved Euphorbia.] Euphorbia, with an upright, strong, succulent, angular stalk, set with oblique tubercles, branches out near the top, and grows five or six feet high; the branches armed with crooked spines, and garnished with roundish deciduous leaves, succeeded by greenish white close fitting flowers.

³**EUPHORBIA Canariensis.**

Canary leafless Euphorbia.] Euphorbia with an upright, four or five-angled, succulent, perennial, green stalk, branching out strongly all around, armed with spines by pairs, and all the branches turning upward towards their extremities, no leaves, but small whitish flowers at the ends of the branches.

⁴**EUPHORBIA Officinarum.**

Officinal Euphorbia.] Euphorbia, with several many-angled, succulent, perennial stalks from the bottom, emitting irregular horizontal branches, gradually turning upward, armed with spines, and from the upper parts, greenish white flowers.

⁵**EUPHORBIA Tithymaloides.**

Tithymaloides, or Myrtle-leaved Bastard Spurge.] Euphorbia with shrubby, slender, succulent stalks and branches; rising eight or ten feet high, oval acute-pointed leaves, ranged alternately on two sides of the branches, and from the end of the branches several scarlet flowers.

Variety.] Laurel-leaved bastard spurge—and with variegated leaves.

⁶**EUPHORBIA Caput Medusæ.**

Caput Medusæ, or Medusa's Head Euphorbia.] Euphorbia with thick, roundish, succulent, scaly stalks, roundish scaly branches, twisting over one another, appearing like many-headed serpents, narrow, thick, succulent leaves, and from the upper parts of the branches, white, close-fitting flowers.

Varieties.] Little Medusa's head, having a short stalk, six or eight inches high, and slender trailing branches, twisting over one another—dwarf-trailing Medusa's head, with swelling scales—low spreading Medusa's head, without

without scales—deciduous, low spreading Medusa's head, with leaves falling soon off—double branching, low, spreading Medusa's heads.

All these species of Euphorbia, are very succulent in stalks and branches, abounding with a milky juice, so extremely acrid, as to burn linen, or blister the hand or any part of the skin, where applied; and the branches being so succulent, cuttings thereof, if preserved dry, may be kept out of the ground several months if necessary, and then planted, will readily emit roots and grow.

They are all natives of the hot parts of Africa, Asia, and America, and retained here in our stoves, as plants of curiosity, for the great singularity of their strange growth.

In their culture here, they must be kept always in pots of very light, sandy, or rubbishy poor soil, and placed upon the shelves in the hot-house.

They are all easily propagated by cuttings of their branches any time in summer; take off the cuttings with a knife, from three to five or six inches long; lay them on a dry shelf till the wound is dried up and skinned over, as for other succulent cuttings; when this is effected, plant them singly in small pots of dry sandy soil, and plunge them in the bark-bed, give a little water once or twice a week, and they will soon be well rooted, and may then be placed upon the shelves in any part of the stove.

They must be allowed larger pots occasionally, once every year or two, but never put them in any too large; waterings will be necessary now and then, which in winter once a week is sufficient, and not oftener than twice in spring and autumn, and about two or three times a week in the heat of summer.

F.

FAGUS, the Beech-tree, and the *Castanea*, or chestnut tree.

This genus retains three hardy deciduous trees, two of them of large and beautiful growth, valuable to cultivate for timber, and for ornamental plantations; the other is a dwarf shrub-like tree for the shrubbery, all of them adorned with beautiful simple foliage, and monoecious amentaceous flowers.

Class and order, *Monoecia Polyandria*.

Characters.] Male and female flowers on the same tree, collected into globular and cylindrical amentums, having monophyllous cups, five-parted in the males, and four in the females. COROLLA none. STAMINA, many filaments in each cup, and oblong antheræ. PISTILLUM, a germen, three styles and simple stigmas. PERICARPIUM, a large roundish spinous capsule, formed of the calix, containing two nuts.

The species are;

¹FAGUS *Sylvaticus*.

The Beech tree.] Fagus, with an upright, straight, smooth trunk, rising sixty or seventy feet high, and of proportionable bulk, branch-

ing upward, into a fine regular head, garnished with oval, serrated leaves; flowers in globular katkins, succeeded by angular fruit called mast.

Varieties.] With yellow striped leaves—white striped leaves—with purplish leaves.

²FAGUS *Castanea*.

Castanea or Chestnut-tree.] Fagus, with an upright large trunk, growing forty or fifty feet high, branching regularly around, into a fine spreading head, garnished with large, spear-shaped, acutely serrated leaves, naked on the under side, flowers in long amentums, succeeded by round prickly fruit, containing two or more nuts.

Variety.] Gold striped-leaved-chestnut-tree.

FAGUS *Pumila*.

Dwarf Chestnut-tree, or Chinquelin.] Fagus with a shrub-like stem, branching eight or ten feet high, oval, spear-shaped, acutely serrated leaves, hoary on the under side.

The flowers of all these trees are very inconsiderable in appearance, those of the beech-tree are collected into roundish heads appearing in May and June, succeeded by the mast, an angular

angular fruit, in autumn; and the flowers of the two species of chestnuts are gathered into long katkins, appearing in May, succeeded by the nuts in autumn, in large, round, prickly covers, each containing one, two, or more nuts.

The first two species may be ranked with the first class of timber trees, both for their ornamental appearance when growing, and their various uses when felled as timber; no trees are more suitable for parks, extensive lawns, large wilderness works and clumps, or on the sides of woods, fields, avenues, and by the sides of large ridings; that besides their ornamental appearance when growing, and expectation of their valuable timber, they afford a plentiful annual crop of fruit for swine, deer, and other animals, and the fruit of the chestnut tree is often eaten at table, and is greatly esteemed by many when roasted; the fruit do not however, always arrive at such perfection here as in Spain, from whence great quantities are annually sent hither in winter.

The beech was formerly much employed to form hedges, to surround the quarters of the pleasure-grounds, according to the ancient mode of dividing the ground into regular squares, angles, &c. it forms a very handsome hedge, when neatly sheared twice every summer, i. e. about Midsummer, and again in August.

The timber of those trees are valuable for many purposes; that of the beech is esteemed by the turners, as also by joiners, for making bedsteads, chairs, stools, dresser-boards, coffins, &c. and as to the chestnut, the uses of its timber are almost universal, not only for building, but for many other strong purposes, as well as for making fine tables, chairs, bedsteads, &c. and all sorts of vessels to hold liquor; as under-wood, it is also superior for poles for hops, and various other uses.

As to the dwarf chestnut, it is only employed for variety in shrubberies, and other ornamental plantations.

All the sorts will thrive on almost all soils and situations, in sandy, gravelly, loamy, or clayey land, either on plains, declivities, or sides or tops of hills.

Propagation and Culture.

First of the beech tree. This is easily raised from the mast or seed, which ripens abundantly in September, and which may either be sown then, or in a month or two after, or towards spring; for which prepare beds four

feet wide, and raking the earth evenly from off the surface, about an inch deep, then sow the mast, and beat it gently down with the back of the spade, and cover it over with the earth the above depth; in spring many plants will come up, others not till a year after, and when they are two years old, plant them out in nursery rows, two feet and half asunder, to remain till they are four or five feet high, or more, and then transplant them, where they are to remain.

Second, the chestnut tree. This tree is also propagated by seeds, i. e. the nuts, which sometimes ripen perfectly in England, but in default of this, there are vast quantities imported annually from Spain and Portugal, which are rather preferable, either of which are to be preserved in sand till February, then sow them in drills; let the drills be made a foot asunder, and near three inches deep, in which place the nuts two or three inches distance, and earth them over, they will soon germinate, and come up freely the same spring; all the culture they require, is to be occasionally hand-weeded, and when two years old, transplant them in February in the nursery rows, at which time, previous to planting, shorten their roots and trim off all side-shoots, then plant them in lines two feet and half distance, and half that distance in the rows; and after having four or five years growth, they will be of due size to plant out for good, either for ornamental plantation, or as forest trees.

If a wood or plantation of these trees are designed for profit, they may be planted any where not too wet, placing them six feet distance, which is sufficient room to grow for poles, when they may be cut down within a foot of the ground, leaving a sufficiency of the most promising at twenty feet distance, to grow up for timber.

The dwarf-chestnut, or chinquepin, is also raised from the nuts, which are procured from America by the seedsmen, and are to be planted in drills, and in every respect as the common sort.

The variegated-leaved kinds are continued by budding, grafting, or inarching in stocks of the common sorts.

FEMINEUS flos, a Female Flower.

A Female Flower, according to the sexual system, is that which is furnished only with the *pistillum*, or female organs of generation, i. e. the germen, style, and stigma, but wants the stamina, or male organs altogether.

They

F E R

They, the Female Flowers, are produced apart from the males either on the same plant, as in cucumber, melon, gourd, mulberry, and other plants of the class *monoecia*; or on distinct plants, as in all the genera in the class *dioecia*. See CLASSIS.

FEMINA planta, a Female Plant, a plant which produces female flowers only, as spinach, hemp, poplar, juniper, *menispermum*, *myrica*, and other genera of the class *dioecia*.

FERULA, Fennel-giant.

The plants are large, herbaceous, flowery perennials, producing annual stalks eight or ten feet high, terminated by yellow umbels of flowers.

Class and order, *Pentandria Digynia*.

Characters] **CALIX**, umbellate flowers, having a caduous general involucre, and a many-leaved partial one, and scarce any calix to the florets. **COROLLA**, a globular general umbel, compose of many quinquepetalous florets. **STAMINA**, five filaments and single antheræ. **PISTILLUM**, a turbinated germen, two styles, and obtuse stigma. **PERICARPIUM**, an elliptical, plane, two-parted fruit, and two seeds.

The principal species are :

¹**FERULA Communis**.

Common Fennel-giant.] *Ferula*, with long thick, juicy roots, crowned by very long many-parted leaves, composed of numerous very long, narrow, undivided segments, spreading widely on the ground, upright, strong, jointed, hollow stalks, ten or twelve feet high, garnished with divided leaves, and terminated by roundish umbels of yellow flowers.

²**FERULA Ferulago**.

Ferulago, or Pinnatifid Galbanum Fennel-giant.] *Ferula* with long, thick, juicy roots, crowned by long pinnatifid leaves, of numerous plane three-parted segments, spreading widely on the ground; upright, strong, jointed, hollow stalks, seven or eight feet high, terminated by roundish umbels of yellow flowers.

Of the juice of the roots of them is prepared the drug *galbanum*.

³**FERULA Tangitana**.

Tangier shining Ferula.] *Ferula*, with very thick juicy roots, crowned by many-parted, shining leaves, composed of numerous jagged unequally three-parted segments, spreading widely on the ground; upright, strong, hollow, stalks, eight or ten feet high, terminated by large umbels of yellow flowers.

F I C

⁴**FERULA Glauca**.

Glaucous Fennel-giant.] *Ferula* with a thick juicy root, crowned by large many-parted glaucous, or grey leaves, of many narrow plane segments, upright, strong, jointed, hollow stalks, six or eight feet high, terminated by yellow umbels.

All these species of *Ferula* have thick, fleshy, perennial roots, spreading and penetrating deep into the ground, leaves spreading widely around; and stalks an inch and half thick, are perennial in root, but annual in leaf and stalk, which rise in spring, flower in June and July, ripen seeds in September, and decay soon after.

They are proper furniture for the large compartments of extensive pleasure-grounds, they will grow any where, but grow tallest and strongest in deep soils.

Their propagation is effected by seed, in autumn or spring, in drills twelve inches asunder, sowing it thinly, and cover it near an inch deep, and when the plants are a year old, transplant the largest into the places where they are to remain.

FICUS, the Fig-tree.

The common fig-tree of our gardens consists only of one species, very comprehensive in the varieties of its fruit, is of the deciduous tribe, moderately hardy, producing fruit in great perfection against walls, also tolerably in espaliers and standards; but besides this sort, there are several other tender exotic species, sometimes retained in our hot-houses, for variety; we shall however first exhibit the culture of the common kind.

Class and order, *Polygamia Trioecia*.

Characters.] **CALIX** androgynous, male, and female flowers upon three distinct plants, included in great numbers within the fruit, which serve as a general calix, or receptacle, each floret having, in the males a three, and the females a five-parted cup. **COROLLA**, no petals to the florets. **STAMINA**, three bristly filaments in the males, and didymous antheræ. **PISTILLUM**, in the females, an oval germen, reflexed style, and two reflexed stigmas. **PERICARPIUM**, none, but the numerous seeds are lodged in the general calix, and which become the fruit.

The fruit of the fig-tree, in the vulgar acception of the word, is the common calix, to the flowers, which are numerous very small florets, that line its internal surface, so that

that they are not visible without opening the fruit or common receptacle.

These flowers are in some trees female only, in others male, and some male and female within the same receptacle.

The species of the common fig-tree is ;

Ficus Carica.

Common cultivated Fig-tree.] *Ficus*, with an upright stem, branching fifteen or twenty feet high, garnished with large palmated or hand-shaped leaves.

The leaves are generally more or less divided into five principal parts.

This tree always produces its fruit upon the young shoots of the former year, rising immediately from the eyes of the shoots, appearing first like small buds, which encrease gradually in size till July, August, and September, when they arrive at full growth, are large, somewhat pear-shaped, and as it approaches to ripeness, the skin changes gradually from a greenish to blueish, purplish, blackish, whitish, or yellow colours in different varieties, full of a purplish, reddish, whitish, or yellow pulp, becomes very soft, juicy, and extremely rich and luscious.

The principal *Varieties* of this fruit are :

Common Fig.—A large oblongish, dark, purple-blue fruit ; the tree a great bearer, and ripens in great perfection in August, either on standards or walls.

Brown or Chestnut Fig.—A large globular, shortish, chestnut-coloured fruit, having a purplish delicious pulp, ripen in July and in August.

Black Ischia Fig.—A middle-sized, shortish, flat-crowned, blackish fruit, having bright pulp ; ripe middle of August.

Green Ischia Fig.—A large oblong, globular-headed greenish fruit, slightly stained through by the pulp to a reddish brown colour ; ripe end of August.

Brown Ischia Fig.—A small pyramidal, brownish, yellow fruit, having a purplish very rich pulp ; ripe in August and September.

Malta Fig.—A small flat-top'd brown fruit ; ripe the middle of August and September.

Round Brown Naples Fig.—A globular, middle size, light brown fruit, and brownish pulp ; ripe end of August.

Long Brown Naples Fig.—A long dark-brown fruit, having a reddish pulp ; ripe in September.

Great Blue Fig.—A largish blue fruit, having a fine red pulp.

Black Genoa Fig.—A large pear-shaped black-

coloured fruit, and bright red pulp ; ripe in August.

Divided-leafed Fig-tree,—having the leaves deeply divided into many narrow segments, valuable principally for the shrubbery for the variety of its leaves.

There are many other varieties, but it is unnecessary to recount them, some of them being nearly alike, and many of them will not ripen perfectly in our gardens.

Most of the above varieties of figs will bear plentifully against walls of a south, east, or west aspects, and will also bear very well in espaliers ; they will likewise in fine dry summers, produce tolerable good crops on standards, in a full exposure, either as full standards, half standards, or dwarfs, and sometimes produce greater crops of fruit than those trained against walls.

Having remarked above, that in fig-trees, it is the year-old shoots only that produce the fruit, this however is often formed upon the shoots the preceding summer, appearing in autumn like very small buds, as aforesaid, at the places of the leaves ; many also come out in spring, from which we are principally to expect our best crops : let it also be remarked, that in autumn after the main crop of ripe fruit is gone, you will generally see many green fruit remaining, quarter or half grown, these are such that are produced early upon the same summer's shoots, which in warm countries arrive also to perfection the same season ; so that they have two crops annually, but these rarely ever attain perfection in England, unless assisted by hot walls, nor will they stand the winter to come to perfection the succeeding year, therefore all these sorts should be pulled off at the fall of the leaf in autumn.

Fig-trees are the most uncertain of any in producing good crops of fruit in England, their young shoots and fruit being both very liable to suffer by frost ; for in some seasons the young shoots do not ripen or harden, but remain soft, pithy, and full of juice, and the winter frosts often kill their upper parts, in which case but little fruit can be expected the succeeding summer, as the fruit is always principally produced towards the extremities of the shoots ; therefore, to preserve the shoots in severe winters, some of the choicest sorts against walls, may be matted during the inclemency of the weather.

It is the robust, short-jointed shoots that are the principal bearers ; the long, straight,

smooth shoots, seldom bear much; the former sorts should therefore be chiefly retained for bearing. See their *Culture*.

All the varieties of these trees prosper in any common soil of a garden, prepared by common digging, or trenching one or two spades deep.

They may be planted at fifteen or twenty feet distance, against walls and espaliers; and as standards, any distance not less than fifteen feet from one another.

Propagation.

The propagation of fig-trees is effected with great ease three different ways, viz. by suckers arising from the root, by layers, and by cuttings.

By Suckers.—The trees commonly send up many suckers annually in summer, which, in autumn following, may be transplanted: in taking them off, go as low as possible to the old root; trim off any ragged part at bottom, leaving their tops entire, especially if for standards, and plant them in nursery lines, two or three feet distance, or may be planted at once, where you design they shall remain to produce their fruit; observing, if they are designed for dwarfs, for walls, or espaliers, they, if long may be headed to six or eight inches in March, the more effectually to force out lateral shoots near the bottom, as observed of espalier and wall trees; but if intended for standards, they must not be topped, but trained with a stem, not less than fifteen or eighteen inches for dwarf-standards, a yard for half-standards, and four, five, or six feet for full standards, and then must be suffered to branch out to form a head, observing, that whether against walls, espaliers, or standards, the branches or shoots must never be shortened, unless to procure a necessary supply of wood, for the fruit being always produced upon the upper parts of the young shoots, that if cut off, no fruit can be expected.

By Layers.—Autumn is the best season, though it may be done any time from October till March or April. Chuse the young pliable lower shoots from the fruitful branches, lay them in the usual way, covering the body of the layers three or four inches deep in the ground, keeping the top entire, and as upright as possible, and they will be rooted, and fit to separate from the parent in autumn, then plant them either in the nursery, or where they are finally to remain, managing them as ordered above for the suckers.

By Cuttings.—Autumn, at the fall of the

leaf, or any time in March, is the time to plant them: chuse well ripened shoots of the preceding summer, short, and of robust growth, from about twelve to fifteen inches long, having an inch or two of the two-years wood at their base, the tops left entire, and plant them six or eight inches deep, in a bed or border of good earth, in rows two feet asunder: and when planted in autumn, it will be eligible to protect their tops in time of hard frost, the first winter, with any kind of long loose litter, managing them afterwards as the suckers.

Culture as wall and espalier trees.

Considered as wall and espalier trees, they should be allowed a sunny situation, being necessary to forward the ripening of the fruit, and promote a rich flavour: they ripen earliest in a full south exposure, but they will also succeed very well in an east and west aspect; and as to distance, fifteen or twenty feet is necessary; against a high wall the former distance is sufficient, but if they are rather low, twenty feet should be allowed.

With respect to training, that having headed down the first shoots, to procure bottom branches, as for other wall and espalier trees, the branches must be laid in a somewhat horizontal position, preserving an equal number on both sides of the tree, ranging to the right and left, at eight or ten inches distance, one above another; for the leaves being large, the branches should be laid wide accordingly, training each also at full length, for reasons before laid down, unless there is an immediate want of wood; a supply of branches, either to give the tree its first due formation for the wall or espalier, or as a farther supply to furnish the wall, &c. in which cases, some convenient shoots contiguous may be shortened to five, six, or eight inches, to force out laterals for the necessary supply; though these trees for the general part, naturally furnish wood enough to render the work of shortening unnecessary.

For, as I before observed, these trees always producing their fruit upon the upper parts of the young wood, the branches should consequently, in the general course of culture, be always trained at full length, as shortening would cut away the only bearing parts, and force out innumerable unnecessary shoots; and it will be found, that the trees seldom fail to furnish a natural supply of successive young wood annually for each year's bearing; observe likewise, that in consequence of the

trees

trees bearing fruit upon the year-old wood only, particular attention is requisite to preserve an annual supply of each summer's shoots in every part of the tree, not only one at the extremity of every branch, but likewise occasionally in the lower parts, quite from the bottom, coming up in successive order, one after another, at proper intervals, between all the principal branches; that every part of the wall or espalier may be occupied with bearing wood; and, as the lower young branches advance upward, the old naked ones that support scarce any young wood, or such that are too high for the wall, must be cut away either to their origin, or to some convenient young lower branch or shoot that they may support, training that up to supply the place of the part cut out. By observing as above, you will be able to have every part of your wall and espalier tree full of fruitful wood, quite from the bottom to top, and side extremities.

With respect to pruning, two principal dressings is requisite annually, to those against walls, &c. that is, a summer and winter pruning and training.

Summer Dressing.—The trees commonly produce great numbers of young shoots every summer, frequently many more than are necessary; some of the most irregular and ill-placed should be taken off, and the rest trained in close and at full length for next year's bearing, that by this regulation the sun and air may be more effectually admitted, to promote the free growth and regular ripening of the fruit, the main object. June, July, and August for this work of summer dressing, observing, that in performing the operation, I would advise to take off only such shoots that are very irregular, and such others that cannot be possibly trained in; for in these trees, it is proper to retain in summer, when practicable, three times more than may seem necessary for the winter or spring training, because the shoots being rather of a succulent, pithy nature, many of them are often killed in winter, so that by reserving them all till the general pruning in spring, there may be a sufficiency escape to chuse from, to furnish the tree, and if more than necessary, they are easily cut out, therefore in this dressing, take off principally only the foreright and other very irregular, and evidently useless shoots, rubbing or cutting them off quite close; let the others be trained to the wall or espalier, between the main branches at full length, still continuing them so, as they advance.

Observe however in the summer dressing, that if there is any great want of wood in any part, you may in June pinch or top any contiguous young shoots, whereby it will furnish a supply of collaterals the same season, to supply the vacancies.

If the above operation of summer dressing is begun early, before the shoots become woody, the redundant young wood may be rubbed off without employing a knife.

Winter or general Pruning.—Having observed above, that many of the young branches of Fig-trees are liable to be more or less damaged in severe winters, in consequence thereof, it is advisable to defer this general pruning till spring, reserving till then all the shoots retained in the summer dressing, and out of the whole, enough may escape the frost for our purpose, and if more than enough, the better, there will be the more to chuse from; but if the general pruning was performed in autumn, or early in winter, and no more shoots left than what is just necessary to furnish the wall or espalier, and many of these should be destroyed by the inclemency of the weather, there is no reserve left to supply the deficiencies; I would therefore advise the general pruning to be deferred till February or March.

This work of winter pruning, consists of regulating the branches in general, old and young, taking out crowding and naked old branches, thinning and selecting the proper supply of young shoots, cutting out all weak and ill ripened ones, and all dead wood.

With respect to the regulation of the principal branches, these should be about eight or ten inches distance, that where they have been trained considerably closer, they should now be thinned, and the contiguous ones all unnailed, that the whole may be trained regular at the proper distance, at the same time examine if there are any old naked branches, i. e. such; that have advanced a considerable length, without furnishing hardly any proper bearing shoots, or young branches furnished with such and that, provided there is proper young wood favourably situated to supply their place; such old naked branches should be occasionally cut out at this pruning, to the place from whence they proceed, or at least down to the first best young shoot or branch, cutting them quite close, never leaving any stump, so train the proper branches and shoots in its stead; having particular attention that every branch terminates in a young shoot, either arising immediately from its extremity,

or in default thereof, or that the end of the extreme shoot is dead, or that the branch is too long for its allotted space, it may be shortened to the next first, second, or third good shoots below, if any, as shall seem convenient, leaving each shoot at full length, unless its end is dead, when it must consequently be cut down to the live wood.

From the principal branches pass to the supply of young wood, produced and trained in the preceding summer, which, if they have escaped the frost, there will be probably many more than is necessary now to be retained; and keeping in view, as we formerly hinted, that they are the only bearers, and a proper supply must be trained now for next summer's fruit: every branch must not only terminate in one at full length, by the rules elucidated above, but collateral ones should also be here and there retained, some towards the bottom of the branches, others nearer the middle, and some more towards the extreme parts, &c. advancing at proper distance one after another, as it were in successive order, between the principal branches; and that besides the supply of fruit they will thus furnish in every part, you will also have your wall or espalier so regularly filled with advancing young branches, that as old branches become naked, or two extensive for the space of walling or espalier allotted, as may be the case in some part or other of the tree every season, there is always a resource of these young branches coming up gradually to succeed them; therefore at every general winter or spring pruning, select in the different parts of the tree, as above, a proper supply of the best shoots, such as are robust, and their buds near together, and arise from the upper or under sides of the branches convenient for training in, at the same time cutting off all long foreright and other ill-placed ones, and all others however good, that are redundant or superfluous, cutting every thing quite close to the surface of the branches, leaving all the selected shoots at full length, where practicable, for the reasons already assigned; never shortening any only in case of dead parts, or want of an immediate further supply of shoots in any part to fill a vacancy.

Having therefore finished this general pruning, let all the branches and shoots be fastened in regular order to the wall or espalier, each at full length, and as straight as possible, preserving all the main branches eight or ten inches distance.

Their Culture as Standard Trees.

Standard Fig-trees, whether dwarfs or half or full standards, after being trained to their proper form, as already directed in the article of propagation, may be planted either in the borders or open quarters of the kitchen garden, or in the pleasure ground, detached from other trees, and not nearer than fifteen or twenty feet to each other.

As to culture, they, in standards require very little training or pruning, all that is necessary, is only taking out any very irregular branch, or when their general branches are too much crowded, to thin them discretionally, taking out the worst and most irregular growing; observing also the same of the young shoots, where they are greatly crowded, thin out some of the ill-placed ones, and such as are weak and ill-ripened, observing, that the shoots and branches are always to be left entire, except in cases exhibited in the wall and espalier culture, as that of cutting off the dead ends of shoots, &c. and thus they will often bear plentifully, and ripen their fruit frequently in as great perfection as against walls.

The Tender Species of Ficus.

FICUS, &c. The following tender species of *Ficus* are preserved in some of our hot-houses, viz. by way of curiosity.

¹FICUS religiosa.

Sacred Fig, or Indian God-tree.] *Ficus* with a woody stem, branching twenty or thirty feet high, heart-shaped entire leaves, ending in long acute points.

This is held in great veneration in India, where it is called the religious tree.

²FICUS Sycomorus.

Sycamore and Mulberry-leaved Egyptian Fig-tree.] *Ficus* with a robust stem, branching twenty or thirty feet high, and large, roundish, heart-shaped, entire leaves.

³FICUS Benghalensis.

Bengal Fig-tree.] *Ficus* with several stems, dividing into many implicated branches, rising twenty or thirty feet high, striking root from their lower parts, and large, oval, obtuse, entire leaves.

⁴FICUS Indica.

Long-leaved Indian Fig-tree.] *Ficus* with a robust stem, branching twenty or thirty feet high, and long, spear-shaped, entire leaves.

⁵FICUS Pumila.

Dwarf Indian Fig.] *Ficus* with trailing rooting stalks and branches, and oval, acute-pointed, entire leaves.

All

All these species are natives of hot countries, where most of them form large trees, but in our stoves appear as shrubs, and their fruit is of no value.

To preserve them here they must be kept in pots and retained in the stove. Their propagation is by cuttings, in summer, planted in pots of light sandy earth, and plunged in the bark-bed.

FILAMENTUM, Filaments, or thread-shaped parts of the stamina, which elevate the antheræ. See **ANTHERÆ** and **STAMEN**.

Filaments are in figure either slender like a hair, awl-shaped, wedge-shaped, or flat, sometimes twisted like a screw, and sometimes bent backwards, as in superb lily, &c. and in many plants are covered with a fine cottony down; and as to proportion, Filaments in some plants are very long, in others very short; of equal lengths, as in most flowers, or irregular and unequal, as in the lip and cruciform flowers, which two last circumstances constitute the classes *Didynamia* and *Tetradynamia*. See **CLASSIS**.

The situation of the Filaments is, in flowers of one petal (*monopetala*), generally inserted into the base of the corolla; in flowers that consist of more than one petal, they are attached either to the calix, as in the class *icandria*; or to the receptacle, as in the class *polyandria*; but in some genera, the Filaments are neither inserted into the calix, corolla, nor receptacle, but into the pistil or style, as in all the genera of the class *gynandria*.

From the number of Filaments in flowers, is founded the first thirteen classes. See **CLASSIS**.

FLOS, the Flower, or parts of fructification of plants, &c.

A Flower is defined to be formed of all the parts of fructification necessary for the generation of all trees and plants, and consists of the following principal parts.

The *Calix*, empalement or cup; the outer green leaves immediately surrounding the corolla or petals. See **CALIX**.

The *Corolla*, petals; or flower-leaves the fine-coloured leaves placed within the calix, and which immediately surround the stamina, &c. See **COROLLA**.

The *Stamina*, or male organs; the slender thread-shaped parts, supporting the antheræ, placed immediately within the corolla, and surround the pistillum. See **STAMEN**.

The *Pistillum*, or female organs; consisting of the germen, style, and stigma, and are placed within the antheræ, and commonly oc-

cupy the centre of the flower. See **PISTILLUM**.

The *Pericarpium*, the fruit or seed-vessel, formed of the germen of the femal organ, and succeeds to maturity after all the other parts of the Flower are decayed. See **PERICARPIUM**.

The *Semen*, or seeds, lodged within the pericarpium, or in default thereof, in the bottom of the calix, &c. See **SEMEN**.

Each of the above parts of a flower is fully explained under its respective head, which see.

But as many Flowers have neither calix nor corolla, they are still to be considered as a Flower, provided it is furnished with the *antheræ* or tops of the male organ, and the *stigma* or summit of the style, the female organ, for the essence of a Flower consists in these two principal organs *antheræ* and *stigma*.

In many plants however we have not been able to discover any resemblance of Flower or fruit, such as the ferns, mosses, mushroom, &c. but it is probable they are all furnished with similar parts, although their minuteness or concealed situation within the plant, prevents any discovery thereof.

FOLIOLA, Folioles, the lesser Leaves or lobes of a compound Leaf.

FOLIUM, a leaf, or leaves, defined to be the organs of vegetation, and principal ornament of plants.

Leaves are such useful and necessary organs, that they attract and transpire the air for the vegetable support and life of the plants, as well as promote the growth of the flowers, fruits and seeds of every sort. Trees perish when totally divested of them at an improper season, witness those which have undergone the depredations of insects and blights; likewise the practice of stripping off some leaves from plants, when we would suspend their growth; and sometimes in cold years, to admit the sun to accelerate the ripening of choice wall fruit; but in this case, it should not be practised till the fruit have acquired nearly their full bulk, and then only just thin out some where they too closely shade the fruit, for the leaves contribute greatly to their growth.

Far the greater number of plants are furnished with Leaves, though in some they are totally wanting, as in the *fungi* or mushroom tribe, shrubby horse-tail, and several kinds of fleshy succulent plants.

All foliated plants and trees however, are not always adorned with Leaves, as for example, all the deciduous tribe are totally divested

vested of them during the winter; but most sorts both deciduous and ever-greens, produce new Leaves every year.

Leaves are of various figures, but generally extended into a plane membranaceous or skinny substance, and formed by the expansions of the vessels of the foot stalk, which divide into many ramifications or branches, crossing each other, form a kind of net, the meshes or interstices, of which are filled up with a tender pulp or pith; this pulpy substance being sometimes consumed by certain insects, whilst the net-work remaining, exhibits the skeleton of the Leaf.

All leaves have one side very distinguishable from the other, an upper and under surface, the former turned towards heaven, the latter downward, and this disposition is so essential to the vegetable oeconomy, that if a branch is overturned in such a manner as to destroy the natural direction of the Leaves, they will, of themselves, in about a week or little more or less time resume their former position, and that as often as a branch is overturned; it is also observable, that from the time the Leaves are turned into a contrary direction, till they have recovered the natural position, the fruit makes hardly any progress in growth, which shews how necessary it is to preserve all the branches of wall and espalier-trees firmly in their proper places, and when any is overturned by wind or other accidents, no time should be lost in fastening them up again, before the Leaves take a wrong direction.

Leaves considered with respect to their form and disposition, may be divided into three classes, Simple, Compound, and Determinate.

Simple Leaves.

Simple Leaves are such as grow singly on a foot-stalk, or a foot-stalk terminated by a single expansion only, either entire or divided; that however deep the divisions, if they do not reach the middle rib, it is still a simple leaf; and as their different shapes, both entire and divided, are numerous, we will here exhibit the most material, each according to the botanic term or name.

Acerosum, chaffy; such as are very narrow and ever-green, as yew, pine, fir, and cedar.

Acinaciforme, scymitar-shaped; being fleshy, spear-pointed, having one edge narrow and convex, the other broad, as in *Mesembryanthemum Acinaciforme*.

Aculeatum, aculeate or prickly; as in some of the thistles.

Acutum, acute; terminated by a sharp point.

Acuminatum, acuminate; having the extremity sharp, like the point of an awl.

Anceps, two-edged.

Bullatum, bullated; blistered, or studded.

Bifidum, bifid; divided into two parts.

Canaliculatum, channelled or fluted.

Carinatum, carinate, or keel-shaped; as in keel-shaped *aloe*.

Carnosum, carnosose, or fleshy.

Cartilagineum, cartilaginous; having a gristly, thick, fleshy edge, different from the other part of the Leaf.

Ciliatum, ciliated or eye-lashed; having the edge surrounded longitudinally with parallel hairs.

Cirrhosum, cirrhose; ending with cirrhi, tendrils, or claspers.

Coloratum, coloured; as in *Amaranthus tricolor*.

Compressum, compressed; having a mark of impression equally on both sides.

Concavum, concave, hollow; the surface hollow in the middle, opposed to convex.

Convexum, convex; the middle rising higher than the sides.

Cordatum, } cordated, cordiform, or heart-shaped, as in the lime-tree.

Cordatum-obverse, obversely cordated, or heart-shaped reverse.

Crenatum, crenated or notched; having the border indented or notched, that the indentings turn neither towards the top nor base, and are termed

—— *acutum*, when acutely or sharply crenated; having the indentures sharp at the ends.

—— *obtusum*, obtuse or bluntly crenated; having the ends of the indentures rounded.

—— *duplicato*, doubly crenated; having small notches on the larger crenatures.

Crispum, crisped, curled; as in curled-mallow, curled-parsley, &c.

Cuneiforme, wedge-shaped; being much longer than broad, narrowing gradually from the top.

Deltoides, deltoid, quadrangled; having four angles, those at the extremities more distant from the centre than those of the sides, as in *Mesembryanthemum deltoides*, and *atriplex Halamus*.

Dentatum, indented; toothed, or having the borders ending in horizontal points.

Depressum, depressed; having a mark of impression on one side.

Delabrisforme,

F O L

Dolabrisforme, hatchet-shaped, is compressed, projecting outward with a sharp edge.

Emarginatum, emarginated; notched at the top, and are termed

—— *acutum*, when acutely emarginated; having the parts on each side, ending in sharp points.

—— *obtusum*, obtusely emarginated; having the two sides ending in blunt points.

Integerrimum, entire; having the borders entire, or free from all indentings or notches.

Ensisforme, sword-shaped; being compressed and edged like a sword.

Erosum, erose, gnawed; the border seems to be gnawed.

Gibbum, gibbous, swollen; both surfaces swelling to a convexity.

Glabrum, glabrous, smooth.

Glaucum, glaucous, grey, or of a sea-green colour.

Hastatum, halbert-shaped; triangular, extended wide at the base, narrowing to a long sharp point at top.

Hirsutum, hairy and bristly; having the surface covered with hairs like shag.

Hispidum, stinging; being covered with hairs, which strike into the flesh.

Laceratum, lacerate, or with a rent, or ragged, irregular border.

Lanatum, woolly.

Lanceolatum, lanceolate, lancet-shaped, or spear-shaped; narrowing gradually from the middle to each end.

Laciniatum, lacinate, or jagged; having sinuses or cuts down to the middle, divided, as it were, into segments, which are jagged on the edges.

Lineare, very narrow, and equally broad; as in rosemary, pine, fir, and the grasses.

Linguiforme, tongue-shaped; being commonly fleshy and compressed.

Lobatum, lobed; divided into two, three, or more lobes, termed,

—— *biloba*, two-lobed.

—— *triloba*, three-lobed.

—— *quadriloba*, four-lobed.

—— *quinqueloba*, five-lobed, &c.

Lunulatum, lunulate or moon-shaped; being shaped like a half moon.

Lyratum, lyre-shaped; divided into transverse segments, the upper ones the largest.

Membranaceum, membranous; without pulp between the two surfaces, as in most.

Nervosum, nervose; having nerves or vessels, extending singly from the base to the extremity.

F O L

Nitidum, shining and glossy.

Nudum, naked; without any kind of hair or pubescence.

Oblongum, oblong; twice as long as broad.

Obtusum, obtuse; blunt, rounded at the extremity.

Orbiculatum, orbicular, round; being orbicularly round, as in *Crassula orbiculatum*.

Ovale, oval, or elliptic.

Ovatum, egg-shaped.

—— *obverse*, obversely egg-shaped, by the small end being affixed to the stalk.

Palmatum, palmated, or hand-shaped; being deeply divided longitudinally down to the base into several parts, spreading out like an open hand.

Panduriforme, fiddle-shaped.

Papillosum, papillose, covered with pimples or vesicles, as in *Mesembryanthemum crystallinum*, or diamond ficoides.

Parabolicum, parabolical; half egg-shaped.

Partitum, partite; being divided down to the base, which if into two, three, four, five, or many parts, are termed.

—— *bipartite*, divided into two parts.

—— *tripartite*, divided into three parts.

—— *quadripartite*, divided into four parts.

—— *quinquepartite*, divided into five parts.

—— *multipartite*, divided into many parts.

Peltatum, peltate, target-shaped; having the foot-stalk inserted into the centre of the lower surface, and not into the base, or margin, exemplified in *Palma Christi* and water-lily.

Pentangulare, pentangular, or five-angled.

Pentagonum, five-sided; having five flat sides.

Pilosum, pilose; covered with distinct hairs.

Pinnatifidum, pinnatifid; being divided horizontally into many long segments, resembling a pinnated, or winged-leaf.

Pinnatum, pinnated. See *Compound Leaves*.

Planum, plane, flat; having an even plane surface.

Plicatum, plicate, plaited, or appearing like folds, by the surface rising and falling in angles, as in *Alchimella*.

Punctatum, punctate; dotted, or set with hollow points.

Quadrangulare, quadrangular; four-edged, or four-angled.

Quinquangular, five-angled; the same as pentangular.

Reniforme, kidney-shaped; as in common *Asarabacca*.

Repandum,

F O L

Repandum, repand, or serpentine; having the edges sinuated in a serpentine manner.

Retusum, retuse; blunted at the end.

Rugosum, wrinkled; having the veins sunk, so that the surface appears uneven.

Sagittatum, sagittate, arrow-shaped; being shaped like the head of an arrow.

Scabrum, rough, rugged; having the surface covered with little irregular tubercles.

Serratum, serrated, or sawed; having the edges notched like a saw, the indentings bending towards the top of the leaf: there are also,

—— *retrosum*, sawed backward.

—— *obtusum*, obtusely sawed; having the indentings obtuse and weak.

—— *duplicatum*, doubly sawed; having small serratures upon the greater.

Sessile, fitting close. See *Determinate Leaves*.

Sinuatum, sinuated; having sinuses or hollows along the border or margin.

Spatulatum, spatula-shaped; being oblong, widening and rounded upward, but narrow below.

Striatum, streaked, or with many slight longitudinal furrows or stripes on its surface.

Spinosum, spinous or thorny; as *Acanthus spinosus*, &c.

Sulcatum, furrowed or ridged; having a number of longitudinal ridges.

Subrotundum, roundish; almost orbicular, only being a little broader or larger, in some part or other.

Subulatum, subulate, awl-shaped; being broadest at the base, contracting gradually to the extremity, into a sharp point.

Succulentum, succulent; generally thick, fleshy, and full of moisture, as in *Aloe*, *Cotyledon*, &c.

Teres, cylindric, and tapering.

Tomentosum, tomentose; downy, closely covered with fine velvety down.

Trilobatum, trilobed, or three lobed; divided into three lobes or segments.

Triangulare triangular; forming three angles, the two lowest being level with the base.

Trigonum, trigonal, three-sided, or three-edged; having three sides, and as many sharp edges, and grow narrow from the base to the extremity.

Triquetrum, three-sided like the former, but the sides are flatter, and the edges not so prominent.

Tetragonum, four-sided.

Truncatum, truncate; when the points seems to be cut off transversely, as in *Liriodendron tulipifera*, tulip-tree.

F O L

Tubulosum, tubulose, or hollow within; as in *Allium*, *Cepa*, the onion.

Venosum, venose, veined; having many branched vessels, like veins running through the surface.

Viscidum, viscid; viscous, clammy or glutinous.

Undulatum, undulate, waved; rising and falling in convexities towards the margin.

Compound Leaves.

A compound Leaf, is that which is composed of two, three, or many smaller Leaves or *foliola*, supported on one common foot-stalk, which assemblage of folioles or lobes, if ever so large or numerous, on one petiola, or general foot-stalk, constitute but one Compound Leaf, *folium compositum*; these smaller leaves or folioles, constituting the compound, are, singly of themselves, small simple Leaves, varying in their form, according to the distinction already given, and are sometimes furnished with short foot-stalks (*petiolatum*) issuing from the main one, sometimes seated close (*sessile*) to the middle rib, without any proper foot-stalk of their own.

Compound Leaves may be divided into three classes or divisions.—1. The compound properly so called, being only once compounded, the *foliola* being supported immediately on the main foot-stalk.—2. Decomposed, twice compounded; the foot-stalk dividing into lesser, and on which the *foliola* are supported.—3. Supradecomposed, several times compounded; the main foot stalk dividing into others, these subdividing into smaller, and on which are supported the folioles: each of which three classes of compound, admit of a variety of modifications, which gives rise to as great a variety of terms, viz.

Binatum, binate; two, formed of two folioles on one foot-stalk.

Ternatum, ternate; three, having three folioles.

Digitatum, digitate, fingered; having several long lobes attached to the top of the foot-stalk, and spread out like the fingers of a hand.

Quinatum, quinate, five-lobed.

Pinnatum, pinnated or winged; having many folioles arranged along each side of the rib, or prolongation of the common foot-stalk like wings, as in *Acacia*, *Sumach*, and hence called pinnated or winged-leaves, of which are the following modifications,

—— *cum impari*, completely pinnated; a winged-leaf terminated by an odd foliole,

hole, proceeding from the extremity of the middle rib.

Pinnatum abrupta, abruptly pinnated; not terminated by an odd lobe.

—— *opposita*, oppositely pinnated; the folioles standing opposite to each other.

—— *alternæ*, alternately pinnated; the lobes placed alternately.

—— *interrupta*, interruptedly winged; the folioles being alternately larger and smaller.

—— *cirrhum*, cirrhus pinnated; the extremity terminated by a *cirrh*, or clasper.

—— *decurrens*, decurrently pinnated; having the folioles running along the mid-rib from one to the other.

—— *conjugata*, conjugate pinnated; paired, the winged-leaf composed of one pair of folioles only.

Decompositum, decompound leaves, or twice compound; having the main foot-stalk divided into smaller, and these smaller ones support the lobes.—And of this kind of compound leaves are:

Biternatum, or *ternatum-duplicato*, doubly three-lobed; the foot-stalk dividing into three smaller, each supporting three *foliola*.

—— *pinnatum duplicato*, doubly pinnated; the main foot-stalk, having smaller ones arranged on each side, and on these are arranged the folioles.

—— *bipinnatum*, doubly-winged, as the former.

—— *pedatum*, pedate, or foot-shaped; the foot-stalk divides, and has the folioles ranged on the inside.

Supradecompositum, supradecomposed, or several times compounded; the main foot-stalk, dividing into others, these dividing into smaller, and upon which are supported the lobes or *foliola*. And admits of the following varieties:

—— *ternatum triplicato*, triple three-leaved; the foot-stalk divides into three smaller, each of these into three others, and each of which support three lobes or *foliola*.

—— *pinnatum triplicato*, triple-pinnated, or triple-winged; the main foot-stalk supporting smaller along each side, these also have smaller ones issuing from both sides, and upon each side of these latter are ranged the *foliola*.

Determinate Leaves.

By Determinate Leaves, whether simple or compound, is not considered their figure, or structure, but their place, situation, and in-

sertion on the parts of the plant, and their direction.

Adpressum, appressed; laid close to the stem.

Adversum, adverse; turns its side towards the south, not upward.

Alternatum, alternate; the reverse of opposite, being placed singly one above another, gradually on each side of the stem.

Amplexicaule, its base embraces the stem quite round.

Axillare, axillary; arising from the angle between the branch and the stem, or that between the greater and smaller branches.

Articulatum, articulate, or jointed; one leaf growing on the top of another.

Caulinum, cauline, or stem Leaves; such as grow immediately on the stalk or stem.

Confertum, confert; growing in clusters.

Connatum, connate; Leaves growing opposite, connect or unite at their base appearing as one, as in some species of honeysuckle.

Decurrens, a decurrent or running Leaf; having the base running along the stem, as in some thistles.

Demersum, demerse; sunk under water.

Dependens, dependent; pointing downward to the earth.

Distichum, distich, two rowed; being ranged along two sides of the branches only.

Erectum, erect; upright, so as to make an acute angle with the stem.

Fasciculatum, fasciculate; clusters from the same point, as in the larch-tree.

Florale, floral; placed near the flower.

Horizontale, extended flat or parallel to the horizon; forming an exact right-angle with the perpendicular.

Imbricatum, imbricate; growing over one another like tiles, or scales of fishes.

Inflexum, inflex; turning the point towards the plant.

Natans, natant; floating on the surface of the water.

Obliquum, oblique; the base rising upward, and the point towards the horizon.

Oppositum, opposite leaves; the reverse of alternate; being such as grow in pairs exactly opposite.

Patens, patent, spreading; recedes from the stem so as to form an acute angle therewith.

Perfoliatum, perfoliate; surrounds the stem or branch, without touching it with its margin or border, appearing as if perforated by the stem running through its disk or middle.

Peltatum, peltate, shield-shaped; having the foot-stalk attached to the middle of its disk,

disk, not to the edge; resembling the form of a shield, or target.

Petiolatum, petiolate, foot-stalked; having a foot-stalk.

Quaternate, four surrounding the stalk at a joint.

Quinternate, five surrounding the stalk at a joint.

Radicale, radical; arising directly from the root.

Radicans, radican, rooting; strikes root in the ground.

Ramosum, rameous, a branch leaf; placed on the branches.

Reclinatum, reclined, bending downward; the extremity lower than the base.

Revolutum, revolute; rolled back.

Semi-amplexicaule, half embrace the stalk or branch, with its base.

Seminale, feminal, or seed-leaf; springing directly from the seed.

Sessile, sessil; sitting close to the stem or branch, without any foot-stalk.

Sparsum, sparred, scattered; placed irregular, without any order.

Stellatum, stellate, starry; several surrounding the stalk at each joint, expanding in a star-like manner.

Ternatum, ternate; three surrounding the stem at a joint.

Vaginant, vaginant, sheath-like; surrounding the stalk like a sheath, as in the grasses and many liliaceous plants.

Verticillatum, verticillate, whorled; many leaves, placed round the stalk at the joints, in whorls or whirls.

The foregoing list of the botanic terms, and short descriptions of the various kinds of leaves, will assist in conveying an idea of their forms and determination, &c. according to the terms used in describing them in the various species and varieties in each genera.

The Leaves furnish very elegant and natural marks in discriminating the species of plants; in no part is nature more various than in the structure of the Leaves, by which very numerous species are determined, and ought always to be studied by the young botanist.

FORCING FRAME, a sort of glass-case, or light building, fronted with glass Frames, in which to force flowers and fruits to early perfection, by aid of artificial heat, either of dung, tanner's-bark, or actual fire.

The general acceptation or meaning of a Forcing Frame is, a fixed erection full to the south sun; the length may be from ten to

fifty, or one hundred feet; the width from five to fifteen, and from five to ten high; having an upright back wall, of wood or brick; and a front of glass-work, made sometimes in one continued range of slope to the top of the back wall; and sometimes with upright glass-work, head high, ranging immediately along the front, and from the top of which a glass roof is carried to the top of the back or main wall; either of which may be for universal use, for the reception of various sorts of flower-plants, small flowering shrubs, and dwarf fruit-trees, &c. occasionally, to force into bloom or fruit in winter, or early in spring and summer; whereby many sorts of the more curious flowers and fruits may be obtained some months before their natural season, which will be a great curiosity, and which is effected, as aforesaid, by aid of dung, bark, or fire-heat; the former (dung-heat) by applying it principally against the outside of the back wall; the second (bark-heat) by forming it into a bed, in a pit within, and the third (fire-heat) by having several returns of flues against the inside of the back wall for the heat to pass along; each of which hereafter described: for these kind of Frames are of different construction, according to the sorts of plants chiefly intended to be forced; and the materials of heat, as dung, bark, or fuel, most convenient to be obtained for forcing them; so that the construction of each kind of Frame is separately exhibited.

Many of these Frames are employed in the vicinity of London, for forcing various plants early for market, particularly for Covent-garden, where, in early spring, in March, April, and May, we shall see exhibited for sale various sorts of flowers, fruits, and other esculents, that would not, in their natural state of growth, have appeared till June or July.

But, for private use, where there is a roomy pine-apple stove, it may also be used occasionally, for forcing many sorts of plants, flowers, and fruits, with equal success, sufficient for the supply of a family.

However, where considerable supply is required for market, Forcing Frames distinct from the pine-stove are also necessary.

In either of these departments may be introduced for forcing, pots of strawberries, kidney-beans, roses, honeysuckles, jasmines, and any other flowering shrubs; likewise carnations, pinks, sweet-williams, wall-flowers, stock-gilliflowers, narcissuses, jonquil, and

and early tulip roots, and any other kind of flower-plants or roots, that may be required early for curiosity; also several kinds of curious annuals, as balsamines, gomphrenas, &c. and may likewise have several sorts of dwarf fruit-trees, as early May and May-duke cherries, peaches, nectarines, apricots, figs, grapes, gooseberries, currants, raspberries, &c.

The general construction of each sort of these Frames is exhibited under separate heads, according to the materials of heat used in forcing them, viz. by dung-heat, bark-bed heat, and by fire-heat.

By Dung-heat.

By Dung-heat.—This is not only the most simple and cheapest kind of Forcing Frame in its construction, but also considerably the cheapest in working, with respect to the article heat, as it may be forced effectually by substantial linings of hot dung against the back and ends.

This Frame is formed with an upright back and ends of deal planking, and a sloping front of moveable glass-lights; the length may be ten, twenty, or thirty feet, or more; the width, from three to five, and five or six high; let the Frame work be of inch deal planking, tongued, and closely joined, that no steam from the dung may penetrate into the Frame; raised five or six feet high behind, and but ten or twelve inches high in front, raising both ends answerable to the front and back; the glass-work to range, from the upright in front, sloping upward towards the back wall, to about a foot width at top, there resting the ends upon proper Frame-work of wood, and bars or bearers three inches width, must range from the back to front, for the support of the lights, as in common hot-bed frames, and the top of all to be boarded wind and water tight; within-side may be two or three ranges of narrow shelves along the back and ends, for pots of small plants, and the bottom levelled, on which to place pots of larger kinds; or you may have shelves rising one behind another quite from the front half way up the back wall, so may place the lowest plants in front, the others in order behind them, rising gradually to the tallest in the back row.

From the above general sketch, you will easily form an idea of the proper construction of a dung-heat Forcing Frame; you may improve as you shall see convenient.

This kind of Frame is much used about London, where dung is so plenty, and easily

obtained; and is there particularly used for forcing roses, or any other small flowering plants, whose flowers have merit in beauty or fragrance—may also try pots of dwarf-cherries, peaches, &c. also pots of gooseberries, currants, and strawberries, carnations, pinks, and the like; having all the sorts in pots separately, and in which they are to be placed in the Frame.

The season to begin to work this Frame, is January and February, and may be continued occasionally till May; but for any kind of fruit trees, the beginning of February is time enough, though those plants of any kind, that are designed to be forced, may be placed in the Frame a month or two before forcing time, to be occasionally protected with the glasses in hard frosts, but at other times, let them enjoy the full air till you begin forcing.

The method of working this Frame is, thus: after having placed the pots of plants in regular order, the tallest behind, and the lowest in front, &c. then put on the lights, and having a due quantity of fresh stable-dung, full of heat, prepared as for common dung hot-beds, let it be piled up close against the back and ends a yard wide at bottom, drawing it gradually into a foot width at top of the Frame, finishing it somewhat sloping, to through off wet; observing, that according as the dung settles or sinks down, a fresh supply must be added at top, to maintain the lining to the full height of the Frame.

This lining will effectually throw in a fine growing heat, and soon set all the plants in motion; observing to give air in the middle of fine days, by sliding one or more of the lights a little down; give also moderate watering occasionally in mild sunny weather, and cover the glasses in cold nights with mats.

In three or four weeks, when the heat begins to decrease considerably, it must be renewed, either by entire fresh dung, or if new dung is scarce, by shaking up the old, taking the worst away, and mix the remainder with a due quantity of new, working the whole again in a pile close against the back and ends as before, which work must be repeated every three weeks or month, or as often as you shall see occasion; for the heat must be constantly preserved to a regular brisk temperature.

A Frame of the above construction may be appropriated entirely for fruit trees, planting them in a border prepared within the Frame

against the back wall, and trained in the manner of wall-trees to a trellis, ranged five or six inches from the back erection; in which may be planted early dwarf-cherries, peaches, nectarines, apricots, grapes, figs, currants, &c. so may be worked by dung-heat against the back of the Frame as above directed; beginning in February, and continuing the glasses on, as well as support the dung-heat until May, and there is no doubt, with good management, but that the different sort of fruit may be brought to perfection early.

By Bark-bed heat.

By Bark-bed heat.—This kind of Forcing Frame is worked by aid of tanners bark hot-bed, formed in a pit within-side the whole length. See BARK-BED and BARK-PIT.

This Frame may be formed either of wood or brick-work, and fronted, &c. with sashes of glass like the former; the length may be ten, twenty, or thirty feet, or more; eight or ten wide, and six or eight high: and may be constructed either nearly like the dung-heat Frame, six or eight feet high behind, and one in front, the ends conformable, and sloping Frames of glass-work raised from the front, sloping either quite to the top of the back wall, or to incline only about one half towards that part, meeting a tyled roof at top half way, which should be raised high enough in front to throw the water off behind, as well as to admit as much sun as possible to every part of the Frame; or it may be constructed with an upright front of glass, head high, and a sloping roof of glass-work, ranging from the upright front, to the top of the back wall, which is rather the most eligible form, both for convenience and benefit of the plants; either of which constructions may be erected detached, or against a south wall already built, which will serve for the back, and save some expence; the ends may either be of wood or brick, but would be much better if glazed like the front, &c. and the glass-work in every part should be made to move on and off, as well as to slide backward and forward to give air, and to do other necessary work; and at one end next the back wall, may be a door to enter occasionally; and within-side must be a pit for the bark-bed, three feet deep, continued the whole length, and width, except about a foot and half alley to go in to perform the necessary culture, as well as to view and gather the produce of different plants.

The pit within is to be filled with new tan any time in winter or spring, you intend to begin forcing, though January is soon enough, and the beginning of February is not too late; the bark will support a growing heat three months, and if then stirred up to the bottom, will renew its heat, and continue it two months longer.

In this Frame may plunge in the bark-bed, pots of roses, or any other choice flowering shrubs you would force into an early bloom; likewise may place pots of strawberries towards the front and top glass, and pots or troughs of kidney-beans may be placed in any part of the Frame; also pots of dwarf fruit-trees, before mentioned, pots of double pinks, carnations, and any other moderate-growing fibrous-rooted perennials, as well as any sorts of bulbous, or tuberous-rooted flowers, as narcissuses, jonquils, tulips, anemones, ranunculus, and various other sorts.

The heat of the bark-bed will effectually warm the internal air sufficiently to forward any sorts of hardy flowers and fruits to perfection, at an early season; observing, that, although they do not always flower and fruit so abundantly as in the full ground, yet, if there is but a few of any sort, a month or two before their natural season, they, if for sale, will sufficiently pay; and if for private use, they will always be acceptable as a rarity, and curiosity in the family.

Fresh air must be admitted in fine sunny days at all opportunities, by sliding some of the glasses more or less open, keeping all close on nights.

Give water also occasionally in moderate quantities.

When the heat of the bark declines considerably, do not omit forking it over to the bottom, which will revive the decaying heat six or eight weeks longer.

A bark-heat Forcing Frame, nearly of the above dimensions, might be contrived entirely for forcing valuable fruit-trees, having a border within-side along the back wall three or four feet wide, there plant young bearing dwarf fruit trees of any sorts before mentioned, at six or eight feet distance, in the manner of wall or espalier-trees, training them also in the same manner as directed for the respective sorts, in their natural state of growth. The bark-pit should here be almost entirely sunk; in the beginning of February fill the pit with new bark, which will soon set the trees into bloom, and will ripen their fruit early; and the late sorts of fine grapes, which do not ripen kindly

kindly here in the full ground, may be brought to perfection.

But the most eligible general Forcing Frame for various sorts of plants is one of the above-mentioned constructions, having also flues for fire-heat; the walls must be of brick-work, having three or four returns of flues formed of the same materials, running the whole length of the back wall within, to make fires occasionally in severe frosts, or on cold nights; also in very cold damp weather, which will be a great improvement in very early forcing, so that this kind of Frame will be nearly of the plan of a stove or hot-house. See HOT-HOUSE.

In default however, of any of the above kinds of bark-heat Forcing Frames, one might be effected by a common bark-pit, see BARK-PIT; filling it a yard deep with tan, and in which may plunge pots of roses, or any other shrubs, any sort of low herbaceous flowering plants, fibrous, or bulbous-rooted, kidney-beans, strawberries, &c.

By Fire-heat.

By Fire-heat. — This kind of Forcing Frame is worked by actual fire, burned in a furnace behind at one end or middle, from thence communicating the heat by flues or funnels, running the whole length of the back wall in three, four, or more returns one above another, and is often employed for ripening several of the more valuable tree-fruits at an early season; or for forwarding such to perfection, which do not ripen freely in our climate without such artificial aids, particularly some sorts of grapes; and in which Frame the whole bottom-space must be good earth two spades deep, for the reception of the trees, &c. for they are to be planted fully in the ground.

This Frame must be formed of brick-work, at least the back or main wall, for the convenience of having fire and flues, and the whole front, &c. must be glass like the other sorts; the length may be from twenty to forty or fifty feet, or more, though one fire will not warm more than that length; the width may be from four or five to twelve or fifteen feet, and eight or ten high. It may be contrived either of moderate width for one row of trees only, to range against the back wall, or may be capacious enough to have a range of dwarf-trained trees behind, as just mentioned, and some young half or full standards, ranging also from the back to the front, or entirely for standards, especially those of cherries.

If it is therefore intended to have a narrow Frame for only a row of trained trees behind, the width from four to five or six feet is sufficient, having the back or main wall formed of brick or stone, as aforesaid, eight or ten feet high, with several flues within-side, returned over each other, running the whole length of the wall; in the front must be a low wall a foot high, on which to lay a plate of timber, and from which is ranged glass frames or lights in one continued slope to the top of the back wall, there received into proper frame-work; but, for the greater convenience, the lights may be in two tiers or ranges, an under and upper tier, the upper range made to slide up and down over the others, but so as all the glass-work can be moved away occasionally, to admit the full air to the trees after the work of Forcing; the whole bottom-space within this Frame, must be of good loamy earth, or any good garden mould two spades deep, which must be dug or trenched in the common way, then plant a range of trees within five or six inches of the wall, and two or three yards asunder, erecting a trellis behind them, upon which, to train the branches as against a wall or espalier; besides these trees, there may be other inferior plants set in the border in front of the trees, as strawberries, dwarf kidney-beans, dwarf peas, mazagan beans, &c. dwarf roses, or the like, that will not rise high enough to shade the fruit-trees in the back range.

A Frame of this construction, forty or fifty feet long, may be worked by one fire; but if longer, two furnaces for fires will be requisite. For flues, &c. see HOT-HOUSE.

But to have a more capacious Frame both for trained trees and standards, may be of any length from twenty to fifty feet or more, but must be ten or fifteen feet wide, having an upright back wall of brick ten feet high, with flues as above directed, and a low wall in front a foot high, on which is erected upright glass-work, four or five feet perpendicular, and from the top of these, a sloping roof of glass frames, continued to the top of the back wall, supported upon proper bearers three feet six inches distance, having the top glasses in two ranges, an under and upper range, as before advised, both of which, and those of the upright in front, made to slide, and move away occasionally; in this Frame there will be room to walk under the glass-work in any part, and there will be also due room for the trees, both dwarfs and standards, and then having the whole ground-space

space within of pliable loamy earth, as in the other Frame; you may plant your trees some in one range against the back wall, as peaches, nectarines, apricots, grapes, figs, &c. eight feet asunder, erecting a trellis for training them upon; and in front of these may be planted rows of young cherries, both full standards, half standards, and dwarfs, the full standards to have five or six feet stems, the half standards three or four, and the dwarfs one or two foot stems; each sort, both trained trees and standards to be planted when about from three to four or five years old, as soon as they acquire a bearing state, having regular heads of two or three feet extent at first planting. Having procured the trees, and the ground ready for their reception, may then plant one range of the choicer sorts as before noticed, against the back wall, two or three yards asunder, the others in rows from back to front, at eight feet distance, the tallest behind and the lowest in front, at three or four feet distance in each row, making each row range against the intervals of the trained trees behind; or if they are all full and half standards, there will be more room for several sorts of smaller plants under them; and as their branches will be nearer the top glasses, may be of particular advantage, and in the intervals may be planted some low currants, gooseberries, raspberries, strawberries, dwarf-beans, kidney-beans, &c. But in a frame of this dimensions, some plant it entirely with standards, more particularly cherries, as being more moderate shooters and soonest arrive to a bearing state, so as to bear any tolerable quantity of fruit to defray the expence, planting them five or six feet distance, sometimes standard plums, apricots, peaches, and nectarines are also planted.

A Frame of these dimensions, twenty-five feet long may be worked by one fire; but if much more than thirty feet in length, two furnaces for fires, with each, its set of flues, will be necessary.

With respect to the age of the trees, for both the above kinds of fire-heat Forcing Frames, they should be from three to four or five year old, with regular heads of two or three feet extent each way, and just arrived at a tolerable bearing state; no very vigorous shooters must be admitted, but such only that assume a moderate regular growth, and are to be trained in the nursery until they have acquired a proper size, each as directed under their respective genera, whether as wall trees or

standards, or trees proper for the purpose may be had at all the public nurseries: they are to be transplanted into the Frame in October or November to remain for Forcing; but should be permitted to have a year or two's growth here before you begin Forcing them, that they may be firmly rooted, during which time all the glasses should be entirely away, that the trees may have the full air till Forcing time is nearly arrived.

In both the above kinds of Forcing Frames, may also plant some grape-vines on the outside of the front glasses in the full ground, and their stems trained through holes, and conduct the shoots along up the inside towards the glass-work to a sort of slight trellis; keeping the branches quite thin, and they will ripen early fruit in great perfection.

It should however be remarked with respect to grapes, that when intended to have in your Forcing Frame any of the large late kinds, which do not ripen here, without the aid of shelter and artificial heat, it will be more adviseable to have them in a department by themselves, because they often do not ripen till late in autumn, so often require the glasses to be continued over them occasionally all summer, especially in wet and cold weather; and sometimes, if the autumn proves wet and cold, they require aid again of gentle fires made them on nights, to promote their ripening perfectly; in which cases, were other trees, whose fruit are ripe and gone in summer, planted in the same department, it would force them at an untimely season, and greatly weaken them.

The season for beginning to make the fires for forcing the trees, in either of the above described fire-heat frames, is any time in January, though about the middle, or towards the latter end of that month is, for the general part, rather the most successful time to begin the general forcing, to have a good crop; for if the trees are forced very early, there will be some danger of their miscarrying, as if they should come into blossom, when severe weather prevails, that air cannot be freely admitted, they seldom set any tolerable crop of fruit; therefore, by beginning to make the fires about the time above directed, the trees will be in blossom about the middle of February, when we may expect some fine sunny days for the admission of a moderate portion of fresh air, which is essentially necessary to promote the natural impregnation of the fruit, and improve its free growth,

growth, for if kept too close, they are apt to drop off in their infant state.

The fires are to be lighted in the furnace every evening about four or five o'clock, and if kept burning till twelve, it will sufficiently heat the flues to warm the internal air of the house till next day in the evening, unless very cold, frosty, or cloudy damp weather set in, then a moderate fire may be made occasionally also in a morning, but by no means force the trees too much, for a moderate warmth will prove the most successful; and thus continue the fires occasionally till April or May, but less in proportion as the weather grows warmer.

Fresh air must be occasionally admitted in fine days, by sliding some of the glasses a little open, and, as the trees advance to blossom and fruit, the days grow longer, and the power of the sun greater, allow a greater proportion of air accordingly.

Thus your trees will be in full blossom in February, and some sorts will ripen fruit in April, particularly cherries and strawberries in plenty; you may also expect early apricots, peaches, and nectarines in May and June, plums and grapes in June and July, but the curious large late sorts of grapes, which do not ripen here without shelter and artificial heat, will not be ripe till September; but these should always have a separate department.

After the fruit of the different sorts are all gathered, the glasses should be taken entirely away, that the trees may have the full air during summer, and in December they should be placed upon the Frame again, ready for forcing in January.

With respect to pruning, the trained trees, i.e. such that are trained as wall-trees against the trellis, &c. they are to be pruned and trained, every summer and autumn, each sort according to its kind, as other wall-trees, and as directed under all their respective articles; and as to the standards, their requisite pruning is principally in autumn, to cut out any irregular growth, and thinning out any crowding shoots, for the branches must be kept thin and regular, clear of each other, six or eight inches distance; and any stragglers which extend in length considerably more than its neighbour of the same tree, should be reduced to order; and as the branches in general become so long, as to press against the glasses, or spread too much, they should also be reduced a little, to preserve them within

due compass, observing always when shortening the standards, it is necessary to cut to a bud, situated on the outside of the shoot or branch, making the cut on the inside; but for particulars in pruning, both the trained trees and standards, see their respective genera.

Every autumn, after pruning the trees, the borders must be digged carefully one spade deep.

It must be remarked, that the trees in these Frames, if annually forced, are not so durable, nor plentiful bearers as those in the full air; therefore, when you shall see any become weak, sickly, or bad bearers, others should be ready in training, or procured from the nurseries, to plant in their stead, and in this no time should be lost.

But to continue the same trees more effectually in health, and in a bearing state, some have a double portion of walling and framing planted, but more particularly that of the first described fire-heat Frame, which is sometimes contrived to move or slide along from one place to another, for one Frame-work and glasses to serve two portions of walling, so that being alternately worked, one part one year, the other the year after, each portion of trees will have a year of rest in their natural growth, and will succeed each other in due order for forcing, whereby the health and vigour of the trees will be better supported, and each year a greater crop of fruit may be expected, than if the same trees were successively forced every year.

FOREST TREES, such large trees both deciduous and ever-greens, that grow in woods and forests, either naturally or cultivated, and arrive to timber, and whose wood is proper for any economical purposes.

Of the Forest Tree kind there are twenty or thirty different sorts of deciduous and ever-greens, which may be employed as such, some to grow to large timber for building, others to compose coppices of underwood, to sell every ten, fifteen, or twenty years for various smaller purposes, in husbandry, building, and many other trades, as exhibited in the culture of the respective sorts, each under its proper genus; but we have collected under this head a list of all the sorts that may be employed in forming woods and other profitable plantations as timber trees, by which any one may see at once the sorts proper for such purposes; and all of which here exhibited are very hardy, and easily raised in the open ground, mostly by seeds, and some by layers and

and cuttings; and all of them succeed in any open exposure; and as in the compass of an estate, the situations and soils may be very variable, some parts may be mountainous, others low, some boggy, some light and sandy, and others loamy, or of a stiff clayey nature, it will be easy to suit any sort according to the soil in which they succeed best, which is always mentioned in their culture; and as such plantations are in general great ornaments as well as improvements to estates, no ground, however barren or unfavourably situated, need lie waste, since there are trees will suit all sorts, and of easy culture; observing however, we only give the lists here, of the proper sorts, and as to their general culture, see each respective genera.

We shall exhibit them under two heads, viz. deciduous and ever-green kinds.

Deciduous kinds.

ACER, the *Maple-tree*—common-maple, greater-maple, or sycamore-tree—Norway-maple—ash-leaved-maple.

ÆSCULUS, *Horse-chestnut*—common horse-chestnut.

BETULA, the *Birch-tree*—common birch-tree—*betula alnus*, or alder-tree.

CARPINUS, *Horn-beam*—common horn-beam—flowering horn-beam.

CELTIS, *Nettle-tree*—common black-fruited nettle-tree—purple-fruited nettle-tree.

CORYLUS, *Hazle-nut-tree*—common hazle-tree.

CRATÆGUS, *Wild Service-tree*—maple-leaved service-tree.

FAGUS, *Beech tree*—common beech-tree—*fagus castanea*, or Spanish chestnut-tree.

FRAXINUS, *Ash-tree*—common ash-tree.

JUGLANS, *Walnut tree*—common walnut-tree—black Virginia walnut-tree.

PINUS, *Pine-tree*—*pinus larix*, or larch-tree.

PLATANUS, *Plane-tree*—oriental plane-tree—occidental plane-tree—black Spanish plane tree.

POPULUS, *Poplar-tree*—white poplar, or abele-tree—black poplar—trembling poplar, or aspen-tree.

PRUNUS, *Plum-tree*, including the *prunus cerasus*, or cherry-tree—wild black-cherry-tree—wild red-cherry-tree—*prunus padus*, or bird cherry tree.

QUERCUS, *Oak-tree*—common English oak—willow-leaved oak—chestnut-leaved oak.

SALIX, *Willow-tree*—common white willow—red willow—broad-leaved sweet-scented

willow—yellow cultivated willow—pendulous, or weeping-willow—fallow, or oval rough-leaved willow—osier, or long-shooting willow, and several others. See SALIX.

SORBUS, *Service-tree*, *Mountain-ash*—common mountain-ash, or wild *forbus*—sweet or eatable service-tree.

TILIA, *Lime or Linden-tree*—common green-twigged lime-tree—red-twigged lime-tree.

ULMUS, *Elm-tree*—common upright English elm—broad-leaved wych-elm—narrow-leaved wych-elm—Cornish small-leaved elm. See ULMUS.

Ever-green kinds.

BUXUS, *Box-tree*—common broad-leaved tree box—narrow-leaved tree box.

CUPRESSUS, *Cypress-tree*—spreading-cypress.

ILEX *Holly-tree*—common green holly.

JUNIPERUS, *Juniper-tree*—red Virginia cedar.

LAURUS, *Bay-tree*—common bay-tree, and varieties.

PRUNUS, *Plum-tree*—*prunus lauro-cerasus*, cherry-bay or laurel-tree.

PINUS, *Pine and Fir-tree*—wild pine, commonly called Scotch fir—pineaster, or great wild pine—stone-pine—swamp-pine—Weymouth-pine—spruce fir tree—silver fir-tree, and cedar of Lebanon.

QUERCUS, *Oak-tree*—ever-green oak—cork-tree.

TAXUS, *Yew-tree*.

THUYA, the tree of life, or *arbor vitæ*—common *arbor vitæ*.

Of the above list of forest trees, the principal and most valuable sorts here as timber, are, the oak, elm, beech and chestnut, ash, maples, birch and alder, poplar, plane-tree, larch, and the pine and fir-trees; but, as most of the other sorts will grow in any exposure, they might be introduced among the others here and there. In composing woods and other plantations for profit, they will assist both in beautifying the estate, and encrease the value, as they become fit for the several uses for which they are calculated; some to stand for timber, others for underwood, among the rest the willow and hazel should not be omitted, they will grow any where, and will yield no inconsiderable profit; but the oak, elm, ash, and beech are the most valuable of all timber-trees in this country.

Most

Most of the above sorts are easily raised from seed in any common ground in the nursery, some also by layers, others principally by cuttings, as alder, poplar, willow, and laurel.

The seed may be sown in autumn, in October, or November, and some in spring, as mentioned under their respective articles; though all the sorts, if the seeds are properly secured till February, may then be sowed with good success; when the plants are two years old, plant them either where they are to remain, or in nursery rows, to stand until they are three or four feet high or more, and may then be transplanted for good in autumn or winter into the places where they are to remain to form a wood, &c. observing, it is advisable to have the deciduous and ever-green kinds principally in separate plantations; and that if designed to have under-wood, for falling occasionally between the trees allotted to stand for timber, the deciduous kinds are chiefly to be used for this purpose; because the stools of each falling in most sorts, shoot forth again much freer than ever-greens; they may therefore be planted at four or five feet distance, and after eight or ten years growth, they will be ready to thin for the first falling: ever-green kinds in different plantations may also be planted at the same distance, and as they advance in growth, as above, may be thinned out also as under-wood, being careful in the thinning of both kinds, deciduous and ever-greens, to leave enough of the most promising plants to grow up to timber.

But where, in a large extent of ground intended for plantations, to save expence in planting, the seeds are sometimes sowed at once, where the trees are to remain, to compose the woods, having the ground prepared by proper ploughing; drills are drawn two, three, or four inches deep, and three or four feet asunder, the seeds are scattered in the drills, and immediately covered over; then in spring and autumn following, great care must be exerted to hoe down weeds between the rows as the plants come up.

Another method of expeditious planting is, to raise the young plants in the nursery, and after two or three years growth in the seed-bed, plant them out in rows, a yard or four feet asunder, and two feet distance in the rows.

In all large plantations there should be left spacious opens for ridings, to different parts

of the wood, as well as to admit a larger circulation of air to the trees.

In these plantations, by either method, great attention is requisite to keep up good fences, and destroy large weeds, by hoeing, &c. till the trees are advanced in growth, and almost ready for the first fall or thinning.

The first fall or thinning for underwood, must be determined by the size, intended uses, and demand for the materials; as for example, if for poles or such like purposes, or for faggot wood, &c. they will probably be ready in seven, eight, or ten years, when part may be then cut down; another part the following year, so go on annually, till the whole plantation is cut, by which time the first fall will be grown up and ready to cut again, especially of the deciduous kinds; observing at each fall, to leave the most vigorous and thriving trees for timber, which may be left pretty close at first, and thinned as they encrease in bulk, leaving at least a full crop to grow to large timber trees, still preserving the stools between them to cut occasionally for underwood, every seven, ten, fifteen, or twenty years, according to the demand or purposes for which they are intended.

It should be remarked, if intended to plant any boggy or marshy grounds, that alder, poplar, and willow, are the proper sorts which will grow very fast either by small cuttings, or by large truncheons; elder will also grow freely this way.

FOSSE, a sort of ha ha, or sunk fence, ditch-like, five or six feet deep, and ten, twenty, or more wide, formed at the termination of particular parts of pleasure-grounds, parks, &c. to extend the prospect.

These kind of fences are often formed at the termination of spacious lawns, grand walks, avenues, and other principal parts of pleasure gardens and parks, both to extend the prospect into the adjacent fields and country, and give the particular parts of a garden an air of larger extent than it really has, as at a distance nothing of the fence is seen, so that the adjacent park, fields, &c. appear to be connected with the garden.

When a pleasure-ground is situated in a park, or paddock, or adjoins to one, or any spacious field, open to any agreeable prospects, the Fosse is often continued quite round, as far as the prospect is agreeable, either to the adjacent fields, plantation, water, or any other object appearing to view from the walks of the garden.

These Fosses are formed upon two different plans, both however serving the purpose of a fence, and to render the prospect open and airy.

One sort is formed with an upright side next the garden, five, six, or seven feet deep, faced with a wall of brick, stone, or strong post and planking; the other side is made sloping outward from the bottom of the upright wall, &c. gradually with an easy slope to fifteen or twenty feet distance, or if more the better, so as to render the declivity as easy and imperceptible as possible, to take off all stiff and ditch-like appearance; and that if in a field or park, no ground will be lost, as it may be converted into grass, observing, that the top of the upright side should be nearly upon a level with the adjacent ground of the garden, and always a little higher than the top of the slope on the opposite side, and which should be laid with grass corresponding to the adjoining garden-ground, unless it is thought convenient to continue a gravel walk that way; in which case, always preserve a proper verge of grass between the walk and the edge of the Fosse; the sloped side should also have its top always on a level with the adjacent ground of the field, park, or part where it is formed; and that the side being finished with a regular slope from top to bottom, it should also be sowed or laid down in grass, which will preserve the slope always in due form, and at all times appear decent and agreeable to the sight.

In forming this kind of Fosse, if, by reason of wet you cannot go deep enough to form the upright sufficiently fencible against men and beasts, a *cheveaux de frize* of wood-work may be erected along the top, projecting outward in a nearly horizontal position, or as much so as to rise but very little above the level of the top of the perpendicular side on which it is fixed, that it may not obstruct the view, or be very perceptible from the garden.

The next sort of Fosse is formed with both sides sloping, and in perpendicular depth from four to six or seven feet, having a fence near that height arranged along the bottom; the sides may be sloped gradually from the bottom, to twenty, or thirty feet width, or more at top, for the more easy and imperceptible the slope the better, but more particularly on the field side, for the reasons before given, and the sides to be also sowed or layed with grass. In this kind of Fosse, as both sides being

sloped, consequently a fence along the bottom is necessary as a defence against cattle, &c. which may be either strong paling, or any kind of pallisado-work, the height in proportion to the perpendicular depth of the Fosse, for the top should not be higher than that of slopes.

The method of forming both these kinds of fences is as follow:

If it be designed to have the first described Fosse, i. e. one side perpendicular, the other sloping, proceed thus: set out the intended width by two ranges of short stakes, then level in the stakes by notching, according to the intended height of the top on each side, corresponding with the adjacent ground as aforesaid; and then make up both the top lines with earth firmly, according to the line of level marked on the stakes; this done, then close along the side of the line of the intended upright side, proceed to dig a trench three feet wide, perpendicularly to the intended depth of the Fosse; as you go on, work also the sloping side gradually down, still continue digging the trench perpendicularly next the garden, &c. till arrived at the proper depth; then level the bottom equally along according to the lines of level at top, and having proceeded so far, then, according to the line of level at top and bottom, trim and finish off the sloping side regularly, so as to form an even slope from the outside line at top, to that at bottom: as to the upright side, a wall must be erected to the height of the line of level at top; making good the ground behind the wall, firmly, as the building advances, and finish the top with a coat of turf level with the adjoining ground; at the same time finish also the slope, either by sowing it with grass-seed, or laying it with turf as shall be most convenient.

To form the other sort of Fosse, with both sides sloping: set out the width by two lines of stakes, level them in, and make up the ground of each line according to the mark of level, as directed before in the former; then exactly along the middle, between the two lines of stakes, dig a trench two or three feet wide, to the intended depth of the fence, sloping each side a little as you go on, still continuing the trench perpendicularly, till arrived at the due depth; then, as in the former, level the bottom an equal depth, by stakes agreeable to the lines of level at top: when this is effected, finish off both slopes evenly from each line of level at top, to that at bottom, and sow each slope with grass or turf

turf as you shall think proper; and with respect to the fence along the bottom, it may be either close paling, rails, or palisadoes, as is most convenient, the height proportionable to the depth of the Fosse, but not to be higher, or at least but very little above the line of level at top of the Fosse.

FRAGARIA, the strawberry plant.

The plants are low, herbaceous, hardy perennials, growing in large leafy tufts, close to the ground, producing slender annual stalks a few inches high, crowned by many beautiful fruit of admirable fragrance; hence it derives the general title *Fragaria*.

Class and order, *Icosandria Polygynia*.

Characters.] CALIX is monophyllous, plane, and ten-parted at top. COROLLA, five roundish spreading petals, attached to the calix. STAMINA, twenty short awl-shaped filaments, and moon-shaped antheræ. PISTILLUM, numerous germina, collected into a head, and many styles, having simple stigmas. PERICARPIUM, none, but a roundish large soft receptacle, or fruit, having numerous small sharp-pointed seeds scattered over its superficies.

There is but one real species of the common strawberry, which is comprehensive in many varieties of its fruit.

The species are;

FRAGARIA Vesca.

The cultivated Strawberry.] *Fragaria*, with a thick fibrey root, crowned by a large cluster of oval-lobed leaves, many trailing strings or runners rooting and forming plants at every joint; and amidst the leaves several slender flower-stalks, six or eight inches high, crowned by a cluster of small white flowers, succeeded by large roundish berries of different sizes and colours in the varieties.

The principal *Varieties* are:

Wood Strawberry (Sylvestris.) Having oval sawed-leaves and small round fruit, and of which there are—red-fruited wood-strawberry—white wood-strawberry—greenish pineapple tasted wood-strawberry—double-blossomed wood-strawberry—and with gold striped-leaves—silver-striped leaves.

Scarlet, or Virginia Strawberry (Virginiana.) Having oblong, oval, sawed-leaves, hoaryish underneath, and a roundish scarlet fruit; and of which there are—common scarlet strawberry—roundish-leaved large scarlet-strawberry—striped-leaved scarlet-strawberry.

Hautboy, or Musky Strawberry (Moschata.) Having oval-lanceolate, rough leaves, and

large, pale, red fruit; of which there are—oval fruited hautboy-strawberry—globular-fruited hautboy—pine-shaped hautboy—green-fruited hautboy—red-blossomed hautboy—white-striped-leaved hautboy—yellow-striped-leaved hautboy.

Chili Strawberry (Chiloensis.) Having large oval, thick, hairy leaves, large flowers, and very large firm fruit; of which there are—round, pale-red Chili strawberry—oblong, pale-red Chili strawberry—round, scarlet Carolina strawberry—white Chili strawberry. These Chili strawberries were first introduced into Europe from Chili, in America; they are considerably the largest fruit of all the strawberry kind, though not always good bearers, but I have sometimes had them bear wonderful great crops, even superior to the scarlet kind; and for the singularity of their large beautiful fruit, should never be omitted in the strawberry collection.

Alpine, or Monthly Strawberry (Alpina.) Having small oval leaves, small flowers, and moderate-sized, oblong, pointed fruit, of which there are—scarlet Alpine strawberry—red Alpine strawberry—white Alpine strawberry. These varieties grow naturally on the Alps; they possess this singular property more than the other sorts, that all the young plants, formed every summer, upon their runners, shoot up into flower and fruit the same year, whereby a fresh crop of fruit is continued monthly in the old and new plants, from June until November or December; the plants are always great bearers, and prosper any where, and the fruit is of a fine poignant agreeable flavour.

All the above varieties of *Fragaria* are hardy low perennials, durable in root, but the leaves and fruit-stalks are renewed annually in spring; shooting up to flower in May and June, and their fruit arrive to perfection in June, July, and August, and which in the Alpine kind as aforesaid, continue till the beginning of winter. They all prosper in any common garden soil, producing abundant crops annually, without much trouble, and encrease exceedingly every summer, both by off-sets or suckers from the sides of the plants, and by the runners or strings, all of which rooting and forming plants at every joint, each of which, of either sort, separately planted, becomes a good plant the same year, and produces a few fruit the year following, but bear in great perfection the second summer; tho' young plants of the Alpine strawberry, planted

out soon after they are formed, bear fruit the same season, as will also the runners of them; for this sort is the most prolific of all the varieties of *Fragaria* yet known, as not only its runners form plants at all the joints as they go on like the other sorts, but the same young plants, as before observed, shoot up into flower and fruit, and the fruit also attains good perfection the same season; which in all the other sorts, the young plants rarely produce fruit until they are one year old, and sometimes not till they have two years growth.

All the sorts are commonly cultivated in kitchen-gardens, in beds or borders of common earth, in rows length ways, fifteen or eighteen inches distance; the plants the same distance from one another in each row.

Patches of the different sorts disposed here and there in the fronts of the different compartments of the pleasure-ground, will appear ornamental both in their flowers and fruit, and effect an agreeable variety.

A plantation of strawberries will endure several years, observing however, that the plants are always in the greatest perfection of bearing in the second, third, or fourth years; therefore, to have plentiful crops of large handsome fruit, a fresh plantation should be made every third or fourth year, for altho' the plants may continue healthful and strong much longer, and flower abundantly, yet most of them are apt to become sterile, i. e. produce flowers deficient in some of their generative parts, particularly the *pistillum*, or female organs either in whole or part, in which case they produce none, or at best, but very small irregular fruit; and young plants taken from such for propagation, retain the same degree of sterility of the parent.

The flowers of all the varieties of strawberries have each five small roundish petals, and are hermaphrodite, and not male and female in different plants, as advanced by the author of the Universal Botanist; for as both the male and female organs are contained in the same flower upon the same plant, they must consequently be hermaphrodite, and the class and order determine it: *Icosandria Polygynia*, twenty stamens and many styles.

The earliest sorts are the scarlet Alpine, and the white and red wood varieties; the hautboys next, and the Chili last of all, but they all attain perfection in June and July.

But they may also be obtained at a much earlier season by aid of artificial heat, even in

winter and spring: see their culture in Hot HOUSE, &c.

Propagation.

The propagation of strawberries may be effected by seed, particularly to obtain new varieties; but the common method of propagation is by young plants which all the sorts furnish abundantly, both by off-sets from their sides, and runners or strings, which, rooting as they go on, form plants at each joint, and those, both of the off-sets and runners, become proper plants the same year, fit for forming a new plantation the following autumn, always making choice of those young plants near the old root.

The season for this work is any time in autumn, August, September, or October, but the sooner the better, or if omitted in autumn, it may be done in spring, but I greatly prefer an early autumn planting, for the plants will be much stronger and better prepared to produce a few fruit the following year, which is rarely the case with the spring-made plantation; but to have a supply of as good plants as possible, it is proper in June, July, or beginning of August, to take off a quantity of the first formed young plants, particularly those formed nearest the parent, raising them up carefully with fibres, and trim off all the strings or running part, then plant them in a shady border by way of nursery, six inches apart, give a good watering and repeat it often in dry weather, and by September or October they will be strong and in much finer order for planting out for good, then those that remain till that time in the beds. If you however should omit the above method, I would advise, if possible, in August or September to take opportunity of showery weather, and make a plantation at once in the places where they are to remain; but by no means be later than October, otherwise the plants will not take root sufficiently before winter, and will be liable some to be thrown out, others forced into the ground during that season, by the weather and vermin; and at any rate will be so weakly in spring, as not to produce any fruit the ensuing summer. As to a spring plantation, it may be performed, if thought convenient, when omitted in autumn, but the plants will scarce produce fruit that year; they however will have the summer before them to acquire strength before winter, so as to be able to produce some fruit the next season.

In the choice of the plants for making your plantation, by no means take them from very old beds, but such that are in the second or third year of their bearing, and that are remarkable for bearing plentifully, because, as before noticed, some plants may appear very healthful, and flower strong, yet produce but very little fruit, occasioned by most of the flowers being deprived of the female organs, for they frequently have numerous stamina and no style; observe likewise, in taking off the young plants, that of such off-sets or suckers you may take immediately from the sides of old plants, to chuse those situated quite on the outside; and that are only of one summer's growth, rejecting such that have knobby hard roots; and of plants produced from the runners, chuse principally those robust ones, which grow next the parent plant, those at a distance toward the extreme part of the runner are not near so proper; being careful to raise them up with as much root as possible, trim off all stringy parts, broken leaves, and straggling fibres, and they are ready for planting.

A free situation open to the full sun is rather necessary for these plants, principally to give the fruit flavour; though, for the sake of continuing a longer succession, some of the wood, scarlet, and Alpine kinds may be planted in different exposure to have more or less sun.

With respect to soil and its preparation, all the sorts will succeed in any common garden earth, as before observed; but if it is inclinable to a loamy nature, it will be a particular advantage; however, be in no great anxiety about soil, take what your garden affords, and if very poor, add some rotten dung, and dig the whole one spade deep; then form the ground into beds four feet wide with two feet wide alleys between bed and bed, for the convenience of having always sufficient room to go in to hoe, dig, weed, water, and gather the fruit; but do not form the alleys deep, only just tread them out by line, then rake the beds over, and line the edges straight; or you may prepare borders by the sides of walks for the reception of some of each sort, where they will be both profitable and ornamental.

Having the ground and plants ready, then proceed to plant them by line and dibble, in rows lengthways, the bed or border fifteen inches distance for the wood, eighteen for the scarlet hautboys and Chili kinds; I would also advise the rows of Alpine strawberries to

be a foot and a half distance, for although the plants are of more humble growth than the three last mentioned, yet, as they send forth many runners, and as these are prolific the same season, let them have room, that their runners may have full scope to root and fruit as they advance; and thus by allowing all the sorts room, you will find your account in the size, quantity, and quality of the fruit; and to give them still greater scope, let each sort be planted in the quincunx order.

As soon as planted, let them all have a plentiful watering, to settle the earth close about the roots, which repeat occasionally in dry weather for a week or two, till they have taken good root.

General Culture.

Having thus formed your strawberry plantation, we proceed to give direction for their future culture.

The first season of planting requires nothing material to be done till spring, more than lightly hoeing between the plants to destroy any autumnal weeds, they requiring no covering in winter; and in spring, in February, or March, when weeds arise, go over all the ground with a hoe, both to cut up all weeds, and to loosen the surface about the plants; and as in April, May, and June, and during the summer, all the sorts encrease considerably by off-sets, as also by their numerous strings or runners, advancing a considerable distance, rooting and forming plants at every joint, so as to overspread the ground, and greatly crowd the principal plants if not displaced; therefore, according as these runners are produced, it would be of particular advantage to divest the plants of the grossest of them, which will greatly strengthen the crop, and promote fruitfulness both in quantity and size; let them however, at any rate be cleared from all runners in autumn, cutting them away close to the plants; clear-off also all weeds, and then they will remain clean and decent until the return of spring again, when the work of hoeing the beds and stringing the plants must be occasionally repeated during summer and autumn; which operation should be performed every year, and if in every autumn after the first, the alleys are dug, and some earth spread between the plants, it will prove very beneficial, as directed below.

The second year of their growth you may expect a general blossom and full crop of fruit.

Every

Every summer, when the plants are in blossom, if the weather should then prove dry, good watering is absolutely necessary, which should be continued plentifully every day or two, from the first appearance of the blossom till the fruit is set and advanced considerably in growth; otherwise the blossom, though abundant, will drop without setting half a crop of fruit, and that which stands will not attain its due size; but if a moist season happen at the above period, watering is unnecessary, and a plentiful crop always succeeds.

The ripening of the fruit advances gradually in June, July, and August, continuing in succession in different sorts, six weeks or two months, though in the Alpine kinds, is often continued from June till the beginning of winter.

In gathering the fruit, let it always be taken with about an inch of its stalk, pinching it off, and put it in small baskets, not in too great quantities, lest they bruise one another.

When they are to be sent to market, they should be packed in pottles, i. e. long, upright, narrow chip baskets, holding about a quart or three pints, having a bow-handle at top, and each when filled, should be papered over, and tied down with bafs; then many of these pottles should be packed upright in a large flat boat-basket, and sent to market on men's head, that they may go safe without bruising, as is the practice of the London gardeners, some of whom have several acres of ground entirely strawberries, particularly those in the neighbourhood of Hammer Smith and Brentford.

As the plants being now arrived at a full bearing state, here follows some general hints concerning their annual culture. Every spring, in February, or March, provided the plants have been stringed the preceding summer and autumn, to preserve them in distinct bunches, it will prove very beneficial to loosen the earth, by fork-digging lightly, between the rows, being careful to break the lumps, and preserve an even surface; as the summer advances, hoe down weeds according as they appear; and as many runners will always rise from the plants, it will still be of advantage, when opportunity suits, to clear them constantly off all the fore-part of summer, until the fruit has obtained its growth, except the Alpine kinds, which, as formerly observed, produce fruit the same year, as well as the old plants, so that a due quantity of run-

ners should be retained to each plant to furnish a greater succession of fruit during the season; likewise of the other sorts, when intended to have a supply of young plants for a future plantation in autumn, some of the best runners should be reserved to form plants for that purpose. In autumn, after the fruit is gone, give the beds a general dressing, that is, mow or cut down the old leaves, and rake them off, then with a knife or sharp hoe trim off all the remaining runners from each plant, cutting up also all those between them, and all weeds, and draw the rubbish into the alleys, and thus you will form all the plants into distinct bunches; then line out and dig the alleys, burying the rubbish in the bottom, and spread a little of the earth between the bunches of plants, which will exhibit an air of neatness, as well as prove a very beneficial dressing, and no farther care is necessary till spring; when the work before directed in spring and summer may be again repeated, the same also again in autumn, and so proceed annually.

Observe however, that if the work of stringing the strawberry-beds as above in summer and autumn, should be omitted at these seasons, do not fail to do it effectually in spring, in February or March, as above directed in the autumn dressing, digging the alleys and earthing between the plants in the same manner.

Many persons however never bestow much culture on their strawberries, but suffer their runners to spread about, and remain from year to year, covering the whole ground, and form apparently a perfect sward; but the fruit of such plants will be very inconsiderable, both in respect to size and quality, in comparison to those regularly dressed annually.

Some persons again direct the beds to be covered every winter with coal-ashes, cast-off bark of the stoves, leaves of trees, or such like materials, to protect the plants from frost; but this is intirely unnecessary, for the plants are generally hardy enough to resist the severest winter's cold.

Forcing them in Hot-houses, &c. for early crops.

Strawberries may be brought to early perfection by aid of a hot-house, forcing-frame, glass-cases against hot walls, or in common dung hot-beds under frame and glasses, by which ripe fruit may be obtained in January, February, March, or April; the scarlet and Alpine,

Alpine, and wood kinds are the most eligible for this purpose.

For this purpose of forcing, you should be furnished with one or two-year old plants, that is, young plants of off-sets or runners before described, planted into pots or nursery-beds towards autumn, and suffered to take their growth in the open air till the following winter twelve-month: they will then be of proper size for forcing; therefore, in autumn, at the times directed for the natural crops, plant out a quantity of stout young plants either into nursery-beds a foot asunder, or into pots, thirty-twos, and place them in the shade till well rooted, which in November plunge to their rims in a warm border under a wall or hedge, to remain until April, then replunge them in a shady border for the summer, supplying them plentifully with water; do not omit this, and pull off all runners and flowers. In September transplant them with the balls of earth into larger pots, twenty-fours, to remain to fruit; and those in nursery-beds, in the open ground may also be now be transplanted with balls into the same sized pots to remain for fruiting, giving still plenty of water during the dry warm weather; and towards the latter end of October remove them to a warm situation, or into a common frame, where they may be occasionally sheltered from the inclemency of hard weather till December, January, or February, to prepare them the better for forcing at these times.

Having the plants ready as above, then, towards the end of December, or in January, or February, according to the time the fruit is required, place some pots of plants into the stove or forcing-frame, and either plunge them in the bark-bed, if you would have them as forward as possible, otherwise place them upon the shelves, &c. observing always to place them as near the front glasses as possible, for they rarely succeed in the back parts, unless placed upon high shelves near the top lights.

Their culture here is only regular watering twice or thrice a week, just to preserve the earth moderately moist; and you may expect fruit in February and March, or indeed earlier, by beginning to force sooner accordingly.

If you have the convenience of hot-walls covered with glass frames, for forcing fruit-trees, &c. the strawberry plants may in October be turned entirely out of the pots into the border between the trees, a foot asunder, where

they will be firmly rooted by the time for beginning to force the trees, and the same fires will do for the whole.

But where there are not the convenience of hot-houses, &c. the plants may be forced upon dung or tan hot-beds under common hot-bed frames, or in bark-pits, &c.

The hot-beds may be made in January or February, the width and length of the intended frames, and about three feet perpendicular in thickness, placing the frames, &c. on, and when the first flash of great heat is over, put in the plants, previously, if dung hot-beds, laying in some earth or old tan, in which to plunge the pots, placing them as close together as they can stand, filling up closely between all the pots, and as soon as done put on the lights; every day admit fresh air by tilting the upper ends of the glasses an inch or two, being careful to examine the heat; if too powerful, draw up the pots proportionably, to prevent scorching their roots; and when the heat is much decreased, line the bed, if of dung, as directed for cucumbers, &c. when the plants come into blossom they may be moved in their pots to fresh hot-beds, to bring them forwarder, or where this is not convenient, they may be retained in the same bed, by supporting a proper heat, by lining both sides occasionally with substantial linings of hot dung, covering the glasses on nights with mats, still admitting fresh air daily at all opportunities, and give due supplies of water; and thus you may have plenty of strawberries towards the end of March and in April.

FRAMES, hot-bed Frames, and other moveable Frames furnished with glass covers or lights at top, used in gardens for protecting and forwarding tender and early plants.

These Frames are formed of inch or inch and quarter deal-board, made about three yards and half long, and one and a half wide, as high again in the back as in front, to give the top a due slope to the sun, and proper declivity to carry off the wet, which must be covered with glass lights to move on and off occasionally.

But with respect to particular dimensions, they are different according to the sorts of plants they are intended to protect; but generally from ten to twelve feet long, four and half wide, and from eighteen inches to three feet six high in the back, and from nine to eighteen inches in front, the ends made sloping answerably from the back to the forepart; each Frame is furnished with three glass
sashes,

frames, commonly called lights, for the top to move on and off, and slide up and down occasionally; but besides these three-light Frames, one or more two-light, and a one-light Frame of proportionable size may also be necessary for smaller purposes, such as for seed and young seedling plants to nurse them till large enough for the larger Frames; but as the most common Frames for general use are those used in kitchen gardens, in the culture of cucumbers and melons, which also serve occasionally for various other plants, both esculent and flowers, we shall first exhibit the particular dimensions of such kind of Frames, then describe the others for particular uses.

The common kitchen-garden Frames may be of three different sizes, i. e. for one light, two lights, and three lights; the latter of which however are the most material, and which are employed for general use, but it is necessary also to have one or more one-light and two-light Frames, especially in private gardens, the former as a seed Frame, for a small hot-bed, particularly for the seeds of cucumbers and melons for the early crops; and the two-light one as a nursery Frame to the young plants of the same kinds, &c. to forward them to a due size for the three-light Frame.

The one light Frame therefore may be about four feet and a half width from back to front, and three feet six the other way, fifteen or eighteen inches high in the back, and nine in front, with a glass sash or light, made to fit the top completely, to slide up and down, and move away occasionally.

The two-light Frame may be seven feet long, four and half wide, and fifteen or eighteen inches high in the back, and nine in front, having one cross bar, three inches width, ranging from the middle of the back at top, to that of the front, serving both to strengthen the Frame, and help to support the lights; the two lights to be each three feet six wide, made to fit the top of the Frame exactly.

The three-light Frames should be ten feet six inches long, four and a half wide, and from eighteen inches to two feet high in the back, and from nine to twelve or fifteen inches in front; observing that those designed principally for the culture of melons, may be rather deeper than for cucumbers, because they generally require a greater depth of mold or earth on the beds, though Frames eighteen or twenty inches in the back, and from nine to twelve in front, are often made to serve oc-

asionally, both for cucumbers and melons; each Frame to have two cross bars ranging from the top of the back to that of the front, at three feet six inches distance, to strengthen the Frame, and support the lights, and the three lights to be each three feet six inches wide; the whole together being made to fit the top of the Frame exactly every way in length and width.

Sometimes the above sort of Frames are made of larger dimensions than before specified, but in respect to this, it should be observed, that if larger they are very inconvenient to move to different parts where they may be occasionally wanted, and require more heat to warm the internal air, and in respect to depth particularly, that if they are but just deep enough to contain a due depth of mold, and for the plants to have moderate room to grow, they will be better than if deeper, as the plants will be then always near the glasses, which is an essential consideration in early work, and the internal air will be more effectually supported in a due temperature of warmth, for the deeper the Frame, the heat of the internal air will be less in proportion, and the plants being far from the glasses will be some disadvantage in their early growth; besides, a too deep Frame, both in early and late work, is apt to draw the plants up weak, for they always naturally aspire towards the glasses, and the more space there is, the more they will run up, for which reason the London kitchen gardeners have many of their Frames not more than fourteen or fifteen inches high behind, and seven in front, especially those which are intended to winter the more tender young plants, such as cauliflower, lettuce, and for raising early small salad-herbs, radishes, &c.

But Frames designed for the protection of taller plants, should be deeper in proportion, as for example, if designed as a nursery Frame for young pine-apple plants, three feet six by fifteen, or eighteen, will be the proper depth; arranging the largest plants behind, the young yearling ones more forward, and the crowns and suckers of the year in the front of all; a Frame of this dimension may serve also for any of the hardier kinds of low green-house plants, as myrtles, &c. either in default of a proper green-house, or as an easement to one when too much crowded.

A drawing Frame for annuals, i. e. for drawing the larger sorts to a tall stature, such as the *Celosia cristata*, or cock's-comb, and the *Amaranthus*

Amaranthus tricolor, &c. the Frame for this purpose is sometimes made as deep as it is intended to draw the plants in height, and is sometimes composed of three, four, or more different Frames of equal width and length, to place upon one another occasionally, as the plants advance in stature; the former is sometimes made four, five, or six feet high in the back, and three, four, or five, in front, but the front should be glazed to admit the light and heat of the sun, otherwise the Frame would form a kind of deep pit, which would draw the plants up too fast into small weak stems, and they would also be apt to lose all their lower leaves: that part should also be made to open occasionally, for giving water, or a larger portion of air in hot weather; the mode of using this Frame is, that after the plants are drawn about a foot and a half high in any common hot-bed Frame, another hot-bed is made for the deep Frame, in which the plants are placed to remain to grow to their full stature. The other sort of drawing Frame is frequently called a multiplying drawing-Frame, as being composed of different parts, one of the parts may be of the dimensions of a common hot-bed Frame, eighteen inches by nine or ten deep, and on this the glasses are to be placed; the other parts for multiplying the depth occasionally, must be each exactly the same width and length of the first, and a foot deep on every side: and as to the mode of using them, the first or principal Frame having the glasses, is placed first on the bed, and when the plants have reached the glasses, remove this Frame off the bed, and place on one of the others, then place the first Frame and glasses upon that, and as the plants again advance in height, another multiplier must be added, and after that another, always still having the principal Frame with its glasses uppermost, observing, that if the front of each of these Frames, both the principal one and multipliers were glazed, to admit the light and heat of the sun, it would greatly improve the growth of the plants. Another sort of drawing Frame may be formed thus: having one of the common hot-bed Frames with its lights, place it upon the bed, and having four stout posts, one fixed at each corner close to the Frame, four or five feet high, in which are bored holes six inches distance, and four iron or wooden pins are provided, one for each post, and when the plants arrive at the glasses, the Frame is drawn up a little, and the pins fixed in the holes, then rest the bottom

of the Frame upon the pins; and continue raising it from time to time as the plants advance higher. The vacancy at bottom may be easily closed up with boards or garden-mats, and if the front was closed with oiled paper to admit the light, it would be an advantage; it is also proper to have the front to open occasionally for giving air and water.

In all the sorts of Frames of every dimension here specified, the wood-work of the back, ends, and front, should be of inch or inch and quarter deal, as before observed, which should be all neatly planed even and smooth on both sides; and the joints, in framing them together, should be so close that no wet nor air can enter; the cross-bars or bearers at top, for the support of the glasses should be about three inches broad and one thick, and neatly dove-tailed in at back and front even with both edges, that the lights may shut down close, each having a groove or channel along the middle, to conduct off all wet falling between the lights: at the end of each Frame at top, should be a thin slip of board four inches broad, arranged from back to front, joining close up to the outside of the lights, which being necessary to guard against cutting winds, rushing in at that part immediately upon the plants, when the lights are occasionally tilted behind for the necessary admission of fresh air, &c.

With respect to the lights, the wood-work of the Frame should be inch and half thick, and two and half broad; and the bars for the immediate support of the glass-work, should be about an inch broad, and not more than inch and half thick, for if too broad and thick, they would intercept the rays of the sun, so should be only just sufficient to support the glass-work without bending, and should be ranged from the back part to the front, eight or nine inches asunder.

All the wood-work, both of the Frames and lights, should be painted in oil, to preserve them from decay; a lead colour will be the most eligible, and if done three times over, outside and in, will preserve the wood exceedingly from the injuries of weather, and from the moisture of the earth and dung.

The glass-work of the lights may either be laid in lead and well trimmed with cement, air and water tight; or may be laid in the bars of wood in putty, *imbricatum*, i. e. overlaid, or lapping at the ends; the latter method is by some preferred, as being more effectual for the discharge of wet, and the

imbricatures or lapping of the panes being by some left open or unputtyed at bottom, that the rancid vapour naturally arising in hot-beds, and all condensed drops against the glasses, may be discharged at these places, as well as admit a perpetual moderate current of fresh air, proves very beneficial to all plants: this mode however of leaving the lappings open, is by some objected against, especially for very early work, on account of the too free admission of air in cold weather; I however have used them with great success at all seasons, though in the kitchen-gardens about London, where there are vast quantities of framing always at work, their lights are, for the general part, laid in lead, in panes about six or eight inches square: in either method of glazing the best sort of white glass should be used, and the greatest care exerted to make the whole perfectly water-tight.

FRAXINUS, the Ash-tree.

There are three species, all hardy deciduous trees, one of them a lofty forest tree, the others of lower growth, used principally in ornamental plantations, all of them adorned with compound leaves of several pair of lobes terminated by an odd one.

Class and order, *Polygamia Dioecia*.

Characters.] CALIX, hermaphrodite and female flowers on the same and on different trees, having sometimes small monophyllous cups, and sometimes none. COROLLA, either none, as in the common ash; or, as in some species, four narrow petals. STAMINA, two short filaments, and oblong antheræ. PISTILLUM, an oval germen, erect style, and bifid stigma. PERICARPIUM, a compressed fruit, having a single, spear-shaped compressed seed.

The fruit of the ash are commonly called ash-keys.

The species are;

¹FRAXINUS *excelsior*.

Most lofty or common ash-tree.] Fraxinus, with a large upright grey stem, rising sixty or seventy feet high, branching upward into a full regular head, garnished with large compound leaves of five pair of sawed lobes, terminated by an odd one, and small greenish flowers without petals.

Varieties.] With silver-striped leaves—gold-striped leaves.

²FRAXINUS *Americana*.

American Ash. Varieties of this are;

Black American Ash,—having an erect stem, branching twenty or thirty feet high, large very dark leaves, composed of three or four

pair of lobes, and an odd one; small greenish flowers, and broad blackish fruit.

White American Ash—having an upright whitish stem and branches, growing twenty or thirty feet high, light green leaves, composed of about three pair of obtusely sawed lobes, placed far asunder, terminated by an odd one, ending in a very long point, decaying to a whitish colour in autumn.

Red American Ash—grows twenty or thirty feet high, having reddish shoots, large light green leaves, of about three pair of distinctly sawed lobes, terminated by an odd one, five or six inches long, and three broad, decaying to a reddish hue in autumn.

Calabrian Manna Ash—grows twenty feet high, leaves composed of four or five pair of lobes and an odd one; and small greenish flowers: from the exudation of the leaves is collected the manna of the shops.

³FRAXINUS *Ornus*.

Flowering Ash.—Varieties of this are;

Virginia flowering Ash—grows twenty or thirty feet high, leaves composed of three or four pair of sawed lobes far asunder, terminated by an odd one; and large loose bunches of white flowers, at the end of all the branches, furnished with petals.

Dwarf flowering Ash—grows twelve or fifteen feet high, smallish dark green leaves of three or four pair of sawed lobes and an odd one, and small bunches of flowers furnished with petals.

All these three species and varieties are very hardy deciduous trees, the first sort grows common in hedges and woods all over England, but all the others are principally of American growth; all the sorts flower in April and May, of which none but the *Fraxinus ornus* make any appearance, the others being small, apetalous, and greenish; the flowering ash however, is very ornamental in blossom, the bunches being large, and terminate almost every branch, appearing extremely conspicuous; none however but the common ash produce seed in this country, which ripen in great abundance in autumn; but those of all the others are often procured from America by the seedsmen, which, as well as the common sort, grow freely here in any common earth.

The common sort is generally considered as a forest or timber-tree, and as such is very valuable, the timber being excellent for many useful purposes; particularly for almost all sorts of husbandry implements, ploughs, har-

rows,

rows, waggons, carts, axle-trees, wheel-fellies, &c. and the poles of the underwood are proper for hoops, hop-poles, and many other uses; and as the trees grow freely upon almost any soil, and of quick growth, they may be cultivated to great advantage, some to cut every seven, ten, or fifteen years for poles, others left to grow for timber; the loppings are excellent fuel, and burn well, green or dry, so that old pollards, for the purpose of lopping at proper intervals of time, will be very profitable.

But the other two species and varieties are esteemed principally to assist in forming variety in ornamental plantations, but the flowering kinds having the greatest merit for ornament, should be introduced in the most conspicuous parts of view.

Propagation of all the Sorts.

All the sorts may be raised plentifully from seed, which the common sort furnish in abundance; but the other sorts rarely furnishing any here, are procured from abroad, or when their seeds cannot be obtained, they are propagated by budding upon stocks of the common ash.

By seed.—The common sort should be sown in autumn, soon after they are ripe, and those of the others as soon as they can be obtained, which commonly arrive early in spring, and the sooner the better; prepare for all the sorts beds of common earth four feet wide, sow the seeds evenly on the surface, and cover them an inch deep, some of the plants will come up the spring following, and many not till the second spring: when they are a year or two old, prick them out into nursery rows, two feet asunder, and one foot in the lines, and here to remain till they are four, five, or six feet high or more, then transplant them where they are to remain.

By Budding and Grafting.—This is often practised in default of seeds, to propagate the second and third species and varieties, as also to continue the variegated kinds, working all of them upon stocks of the common ash, at the usual season of budding and grafting.

FRITILLARIA, Fritillary, including also the *Corona Imperialis* and Persian Lily.

This genus furnishes a great variety of bulbous-rooted flowery perennials, proper to adorn the compartments of the pleasure-garden, producing annual stalks from about one foot to a yard or more high, terminated by large, bell-shaped, liliaceous flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, is composed of six oblong petals, forming a bell-shape, spreading broad at the base. STAMINA, six filaments, and erect four cornered antheræ. PISTILLUM, an oblong three cornered, germen, simple style, and triple stigma. PERICARPIUM, an oblong, trilobate, trilocular capsule, and numerous flat seeds.

The species are;

¹FRITILLARIA *Meleagris*.

(*Meleagris*) or *alternate-leaved Fritillary*.]

Fritillary, with a depressed, fleshy, bulbous root, an erect flower-stalk a foot or fifteen inches high, garnished with long narrow leaves placed alternate, and the top terminated by one or more large bell-shaped flowers hanging downwards, of different properties in the varieties.—Some finely chequered in regular squares, others of plain colours, as described below.

²FRITILLARIA *Pyrenaica*.

Pyrenean, opposite-leaved Fritillary.] Fritillary with a double, fleshy, bulbous root, an upright flower-stalk twelve or fifteen inches high; garnished with long narrow leaves by pairs opposite, and the top terminated by two or more large bell-shaped flowers hanging downward, of different colours and properties in the varieties.

Varieties of the above two species are—common chequered Fritillary, of which there are several varieties curiously chequered with purple, white, and other colours—dark purple, yellow spotted Fritillary—yellow flowering—great yellow flowering—variegated yellow flowered—white flowered—black flowered—with red flowers—red spotted flowers—large double-flowering—spotted flowered, different varieties—umbelliferous flowering—spiked-flowering—with narrow leaves—broad leaves. All these varieties have great merit in the diversity of their large bell-shaped pendulous flowers, and those of the chequered kinds have particular singularity, being finely chequered in regular squares in a very curious manner, flowering principally in the latter end of March, in April, and some part of May, some late sorts also in June; all of them are succeeded by plenty of seed in autumn.

³FRITILLARIA *Persica*.

Persian Fritillary, commonly called *Persian Lily*.]—Varieties of this are.

Tall Persian Lily.—Hath a round, whitish, bulbous root, an upright firm stalk a yard high,

high, closely garnished with long, narrow, obliquely-waved leaves, and the top terminated by a large pyramidal spike of deep purple flowers spreading wide at their brims.

Dwarf Persian Lily.—Produces an erect stalk a foot and half high, small leaves, and somewhat branching spike of deep purple flowers.

**Fritillaria Imperialis.*

Imperial Fritillary, commonly called Crown-Imperial (Corona Imperialis) Fritillary with a very large, round, scaly, bulbous, yellow root, an upright, thick, succulent stalk, three or four feet high, garnished with long narrow leaves; and crowned by a vast surrounding cluster of large, bell-shaped, pendulous flowers, these surmounted by a large crown of leaves; flowering in different colours and properties in the varieties.

The root of this species and varieties is composed of numerous, thick, succulent scales, and is remarkable for imparting a very disagreeable rank odour.

Varieties of this are; crown imperial with dusky red flowers—with bright red flowers—late red-flowering—double red flowers—golden yellow flowers—pale yellow flowers—yellow striped flowers—double yellow flowers—doubly-crowned, or crown upon crown, having two tier of flowers one above another—triply-crowned, having three tier of flowers—with gold-striped leaves—and with silver-striped leaves. All these varieties are fine majestic plants, of three or four feet stature, making a singularly grand appearance with their large noble crown of flowers, &c and greatly ornament our gardens so early as April and May; all of them so hardy, of easy culture, and encrease so plentifully by off-sets from the roots, that they might be obtained in abundance in every garden.

The flowers of all the four species of *Fritillaria*, and their varieties, have universally a campanulate, hexapetalous corolla, of the liliaceous kind, all remarkable for their pendulous or hanging position; those of the crown imperial considerably the largest, but all of them form a fine variety in the flower-garden.

All the species and respective varieties are very hardy, bulbous-rooted perennials, the roots of great duration, but the flower-stalks are renewed annually in spring; which in the different sorts flower in March, April, May, and June, when, and in July, they ripen seeds, and the stalks then assume a state of

decay, the bulbs become inactive for that season, and ripe for removal, if necessary, either for the purpose of encrease by off-sets, or for transplantation into fresh digged earth, both of which operations may be proper every second or third year, for in that time they will have encreased exceedingly by off-sets into large bunches, and should be divided, and that being planted again in fresh-dug soil, will greatly improve their future bloom.

They all form a fine variety in the principal borders, the two common Fritillary kinds and their varieties shew to best advantage when disposed in three or four roots together, in small patches towards the front of the borders, that is, if they are placed in assemblage with other flowers. The Persian Fritillary or Lily should be stationed rather more backward in the border, and the crown imperials should occupy the middle range behind both these, as being of larger growth, and should always be placed singly, and two or three yards distance in the line; or if you plant the bulbs in beds by themselves, set the Fritillary and Persian-lily kinds in rows a foot asunder, and the same distance in each row, and three or four inches deep; and the crown imperials a foot and half distance each way, and four or five inches in depth.

The season for planting or transplanting all these bulbs is, when their flower-stalks are decayed in July or beginning of August, tho' the bulbs taken up at that time, may be kept out of the ground two or three months, if necessary, by being laid in dry sand; but the Fritillary and Persian-lily are rather more impatient out of the earth than the crown imperial, and therefore should always be put in again as soon as possible.

Observe, it is always proper to remove all these bulbs every second or third year, to separate the off-sets, and replant the whole in fresh-dug ground. See their *Propagation*.

Propagation of all the Sorts.

The more general mode of propagation of all these plants is by off-sets, which they all furnish abundantly from the sides of their roots, and which may be separated every second or third year; the proper time is, when their flower-stalks decay as aforesaid, taking the whole cluster of roots out of the earth, and separate them into distinct roots, planting the smaller off-sets by themselves in nursery beds, to remain a year or two, to acquire a flowering state; and the larger roots, plant where

where they are designed to remain for flowering.

They are also propagated by seed; but this is principally practised to gain new varieties, and the process is tedious; the Fritillary and Persian-lily will be three years, and the crown imperial sometimes six or seven before they flower in perfection.

The seed are to be sown in boxes of light earth in August or September, covering them with earth a quarter of an inch deep, managing them nearly as directed for *colchicums*, tulips, &c. which see.

FRUIT-TREES, comprehending such as produce eatable fruit, either for the desert or culinary uses.

There are about twelve genera of Fruit-trees and fruit-bearing shrubs and shrubby plants that ripen their fruit perfectly in this country, each genus comprising several species, and each species numerous varieties, all of which are exhibited in their respective genera; so in this place we shall only give a list of each genus and its principal species, to shew at one view the genus in which each species is placed according to botanic arrangement.

AMYGDALUS, *Almond-tree*—three species, the almond, peach, and nectarine; of each of which are many varieties, especially of the peach and nectarine. See AMYGDALUS.

CORYLUS, *the Hazel, or Hazel-nut tree*—one species comprising the common hazel-nut of the woods—filbert-tree—Barcelona or Spanish nut—cob-nut, &c. See CORYLUS.

FAGUS, *Beech-tree*—comprising the *Fagus Castanea* or chestnut-tree.

FICUS, *the Fig-tree*—one species comprehending numerous varieties. See FICUS.

JUGLANS, *Walnut-tree*—one species of the common walnut, comprising several varieties. See JUGLANS.

MESPILUS, *Medlar*—comprising three principal sorts. See MESPILUS.

MORUS, *Mulberry tree*—includes three principal sorts. See MORUS.

PRUNUS, *Plum-tree*—includes three principal species—the plum-tree—apricot—and cherry-tree, each comprising many varieties; comprehends also, the bullace-tree, and the sloe. See PRUNUS.

PYRUS, *Pear-tree*—comprises three species—the pear—apple—and quince, each having many varieties; particularly the pear and apple, whose varieties are without end. See PYRUS.

RIBES, *Current tree*; and *Ribes Grossularia*, the gooseberry-bush; each of which comprehensive in many eminent varieties. See RIBES.

RUBUS IDÆUS, *Raspberry*—one species comprising three or four principal varieties. See RUBUS.

VITIS, *the Vine*—one species comprehensive in numerous elegant varieties. See VITIS.

Each of the above genera of fruit-trees, &c. are exhibited in their proper place, and under each are arranged its principal species, with that of the varieties of each respective species, with their proper names, description, propagation, and general culture.

FUMARIA, *Fumatory*.

It furnishes some low, tuberous, and bulbous-rooted, flowery perennials, for the flower-garden; producing annual stalks six or eight inches high, terminated by short spikes of ringent flowers.

Class and order, *Diadelphia Hexandria*.

Characters.] CALIX, two small deciduous leaves. COROLLA, is tubular and ringent, having the lips plane, obtuse, emarginated and reflexed, having a nectarium at their base, and the chops of the corolla four-cornered. STAMINA, six equal, broad filaments, each having three antheræ. PISTILLUM, an oblong germen short style, and an orbicular compressed stigma. PERICARPIUM, a short unilocular pod and roundish seeds.

The principal species are;

¹FUMARIA BULBOSA.

Bulbous-rooted Fumatory.—Varieties of this are.

Hollow bulbous Fumatory (Cava).—Having a large fleshy root, hollow in the middle, crowned by branching leaves, dividing into many small parts, and upright stalks six inches high, adorned with leaves, and terminated by spikes of reddish-purple flowers, in April.

Solid bulbous Fumatory (Solida).—Having a large, round, solid, yellow root; leaves like the former, and stalks four or five inches high, adorned with leaves, and terminated by spikes of purple flowers, in April.

²FUMARIA Cucullaris.

Tuberous-rooted, forked-flowered Fumatory.] Fumaria, with a small, round, scaly root, crowned by leaves divided into three principal parts, each dividing into many smaller; upright leafless stalks, eight or nine inches high, terminated by a loose spike of dull white flowers forked at their base; flowering in May.

FUMARIA

G A L

³*FUMARIA Capnoides.*

Capnoides, or branching ever-green Fumatory.] Fumaria with a fibrous root, sending out many slender tufty stalks, branching eight or nine inches high; finely divided ever-green leaves, and all the branches terminated by loose panicles of bright yellow flowers most part of summer.

Variety.] With a whitish flower.

⁴*FUMARIA Sempervirens.*

Ever green podded annual Fumatory, or Capnoides.] Fumaria, with an upright stalk branching a foot and half high, garnished with branchy finely-divided leaves, and all the branches terminated by loose spikes of pale-purple flowers most part of summer, succeeded by narrow paniculated pods.

The flowers of all these plants are of the ringent or gaping kind, are small, but form a pretty variety.

G A L

All these plants may be employed to adorn the borders of the pleasure-gardens, placing them in small patches towards the fronts of the borders, where they will appear very ornamental.

The third and fourth species are also proper to dispose on the sides of rock-work, grottos, artificial ruins, &c.

Their Propagation.

The two first species and varieties are propagated by off-sets from their roots, in the manner as other bulbous plants, when their leaves decay any time from May till August, which may be performed every two or three years, or according as they multiply.

The third and fourth species are easily raised in abundance from seed, sown soon after they ripen, or in spring, sowing them where they are to remain, or for transplanting.

G.

GALANTHUS, Snow-drop.

It consists of one low bulbous-rooted flowery perennial for the flower-borders, rising but a few inches high, adorned at top with small tripetalous flowers.

Class and order, *Hexandria Monogynia.*

Characters.] CALIX, an oblong spatha opening side-ways. COROLLA, three oblong concave spreading petals, and in the bottom, a three-leaved nectarium. STAMINA, six short filaments, and oblong pointed connivent antheræ. PISTILLUM, an oval germen under the corolla, slender style, and simple stigma. PERICARPIUM, a three-cornered trilocular capsule, and numerous roundish seeds.

There is but one species, viz.

GALANTHUS Nivalis.

Snow drop.] Galanthus with a small, tunicated bulbous root, crowned with several long, narrow, blueish green leaves, and amidst them small angular-naked flower-stalks, four or five inches high, terminated by a spatha, each protruding one small snow-white flower drooping downward.

Varieties.—Common single-flowered snow-drop—femi-double snow-drop—double snow-drop.

These are delightful little plants, considering the early appearance of their snow-white flowers, adorning our gardens often in January and February, when scarce any other flower is to be seen, and frequently bursting forth when the ground is covered with snow, continuing very often till the beginning of March, and make a very ornamental appearance, especially when disposed in clusters towards the fronts of borders, &c.

The single sort comes first into bloom, then the femi-double, and after that the double.

They should be employed to adorn the fronts of flower-borders, the edges of wilderness plantations, the borders of wood-walks, and the fronts of shrubbery-clumps, &c. for they will succeed any where, and multiply exceedingly by off-sets from the roots.

They effect considerably the best appearance when disposed in bunches of several roots together, placing some near the edge of the borders, other bunches a foot or more back, in which order they will form variety more eligibly than in straight rows; or when disposed singly, or by way of edgings to borders, as sometimes practised, in which they cut a straggling appearance at first.

The

G A R

The roots should therefore be planted five or six together at least in a cluster, placing them two or three inches deep, and permit them to remain undisturbed four or five years to encrease into large bunches, they will then form the best appearance.

Their propagation is by off-sets of the roots, the best season for which is June or July, though, they being so hardy, it may be done at almost any time after the bloom; but I would prefer summer for that work, when their leaves decay, and may either be planted directly, or kept out of the ground till October or November; but do not however retain them longer out of the ground than December, otherwise they will flower weak the first year. See BULBUS.

GARDENS. Gardens and plantations are grand, ornamental, and oeconomical improvements to a country seat and estates in general, and may be divided into the following principal districts: The pleasure-garden—kitchen-garden—orchard—nursery—and plantations. For a proper description of each, see PLEASURE-GARDEN, KITCHEN GARDEN, &c.

GARDENIA, Cape Jasmine.

There is but one species, a shrubby, very floriferous ever-green, for the green-house, and hot-house.

Class and order, *Pentandria Monogynia*

Characters.] CALIX, is monophyllous, quinquangular, five-parted and permanent.—COROLLA, a salver-shaped petal, with a cylindric tube, a plane limb deeply divided into five oval segments. STAMINA, no filaments, but five narrow antheræ. PISTILLUM, a germen under the corolla, slender style, and bilobed oval stigma. PERICARPIUM, a bilobed berry, and many seeds.

The species is;

GARDENIA florida.

Gardenia, or flowery Cape Jasmine.] *Gardenia* with a woody stem, branching in pairs several feet high, spear-shaped, entire, shining green leaves, four or five inches long, and half as broad, growing by pairs opposite; and at the sides and ends of the branches large close-fitting flowers, of great fragrance.

The flowers of this shrub, although in their characteristic state reckoned monopetalous, yet they are often semi-double, having two or three series of petals, and often as large as a middling rose.

This plant is a native of the Cape of Good Hope, but will live here in the full air in

G E N

summer, and in a green-house in winter, but flowers best in the hot-house.

It must always be kept in pots of light rich earth.

It is easily propagated by layers and cuttings. Lay down some young shoots in spring, in the earth of the pots, they will readily strike root: and cuttings of the shoots planted in pots in spring or summer, and plunged in a bark-bed, or any hot-bed under glasses, they will be well rooted in two or three months, when they should be planted in separate pots.

GENISTA, Broom.

This genus retains low, shrubby, deciduous, and ever-green plants for the pleasure-ground and green-house, growing from two to six or seven feet high, adorned with small simple leaves, and papilionaceous yellow flowers.

Class and order, *Diadelphia Decandria.*

Characters.] CALIX, is monophyllous, tubulous, and bilabiate. COROLLA, is papilionaceous; the vexillum, oval, acute, and wholly reflexed; the wings oblong, short, and loose; and the keel long and erect. STAMINA, ten diadelphous filaments, and simple antheræ. PISTILLUM, an oblong germen, an ascending style, and acute involute stigma. PERICARPIUM, a roundish, bivalvate, unilocular pod, and kidney-shaped seed.

Hardy Kinds.

¹*GENISTA Sagittalis.*

Sagittated or Arrow-shaped, Jointed-Broom.] *Genista*, with trailing, two-edged, green, shrubby stalks, dividing into many trailing, flat-jointed branches, garnished with small oval-lanceolate leaves, singly at each joint, and close spikes of yellow flowers at the ends of the branches.

²*GENISTA Tinctoria.*

Dyer's Broom.] *Genista*, with upright, shrubby stalks, branching erectly two or three feet high, having taper-striated branches, garnished with spear-shaped, alternate leaves, and from the sides and ends of the branches numerous small yellow flowers.

Variety.—*Dyer's-broom* with spreading branches.

The name *Tinctoria*, or dyer's-broom, to this species is derived from its use in dying; it grows naturally in several parts of Britain, &c.

³*GENISTA,*

³GENISTA, *Anglica*.

English Genista, or Dwarf English Broom, or Petty Whin.] Genista, with shrubby stalks branching two or three feet high, armed with long single spines below, and garnished with small spear-shaped alternate leaves, and clusters of yellow flowers at the ends of the branches.

This species grows wild on heaths and other barren places in many parts of England, but is often admitted into gardens for variety.

⁴GENISTA, *Tridentata*.

Tridented-leaved Portugal Broom.] Genista with upright shrubby stalks, dividing into many three-cornered branches, rising three or four feet high, garnished with three-pointed leaves, and large yellow flowers, singly from the sides and ends of the branches.

Variety. — Low narrow-leaved Portugal Broom.

⁵GENISTA, *Candicans*.

Upright Montpellier Genista, or Cytisus of Montpellier.] Genista, with an upright shrubby striated stem, branching four or five feet high; garnished with trifoliate-leaves, hairy underneath, and bright yellow flowers from the sides of the branches.

Green-house Kinds.

⁶GENISTA *Canariensis*.

Canary Broom, or Ever-green Cytisus, from the Canary Islands.] Genista with upright woody flexible stalks, branching six or eight feet high, into many angular branches, garnished with trifoliate, hairy, ever-green leaves, and spikes of bright yellow flowers from the ends of the branches.

Variety. — With white flowers.

The flowers of all these species of *Genista*, are of the papilionaceous or butterfly kind, having each four petals; the standard, two wings, and the keel. See the *Characters*.

They flower principally in May and June, and furnish plenty of seeds in autumn.

Of the above species, the first five are hardy deciduous shrubby plants for the shrubbery; and the sixth, a tender ever-green for the green-house; they all possess merit as flowery plants, being very floriferous in May and June, and as to the hardy sorts, they are choice furniture for the fronts of the shrubbery-clumps, contiguous to the principal lawns and walks; and the sixth is a beautiful plant for the green house collection, which must always be retained in pots for moving to the green house in winter.

Propagation, &c.

All the hardy sorts are easily raised from seed in a bed of common earth in autumn, i.e. September, October, or November, covering them with earth near an inch deep; they will rise in spring, and in spring following: when the plants are a year old, transplant them in nursery-rows, or if some are planted at once where they to remain, they will succeed better, because, having long tough roots, they do not thrive well by removal when old; the green-house sort may also be raised abundantly by seed in spring, by aid of a moderate hot-bed, sowing the seed in pots, and plunge them in the hot-bed: when the plants are three or four inches high, prick them into separate small pots, and manage them as other green-house kinds.

GENTIANA, Gentian, and *Gentianella*.

The plants are principally hardy, herbaceous perennials, of the flowery and medical kind, of different growths, from three or four inches to three or four feet stature, ornamented with oblong, simple leaves, and largish monopetalous, tubular, four or five-parted flowers.

Class and order, *Pentandria Digynia*.

Characters.] CALIX, is oblong, quinquefid and permanent. COROLLA, is monopetalous, tubular at the base, and four or five-parted at the top. STAMINA, five short filaments, and simple antheræ. PISTILLUM, a cylindric germen, no style, the germen crowned by two oval stigmas. PERICARPium, an oblong bivalvate, unilocular capsule, and numerous seeds.

The principal species are;

¹GENTIANA, *Acaulis*.

Short-stalked blue Gentian, commonly called Gentianella.] Gentian, with thick fibrey roots, crowned by oblong leaves, many flower-stalks but two or three inches high, exceeded by the corolla, garnished with spear-shaped, close-fitting, opposite leaves; and at top, large, bell-shaped, five-parted, erect, azure-blue flowers, of great beauty, appearing in May.

²GENTIANA, *Asclepiadea*.

Asclepias-leaved Gentian.] Gentiana, with thick fibrey roots, crowned by oval-lanceolate leaves, flower-stalks a foot high, garnished with oval, spear-shaped amplexicaule, opposite leaves, and from each side largish, bell-shaped, blue flowers by pairs, appearing in June and July.

³GENTIANA,

GENTIANA, Crucata.

Cross-wort Gentian.] *Gentiana*, with creeping fibrey roots, weak flower-stalks six inches long, garnished with spear-shaped, opposite leaves by pairs, each pair crossing the other, and four-parted, light blue flowers, in whorls below, and in clusters at top, appearing in May.

GENTIANA Lutea.

Great Yellow Gentian.] *Gentiana*, with thick, carrot-y yellow, roots, crowned by large, oval, oblong-pointed, veined, stiff leaves; strong flower-stalks three or four feet high, garnished with smaller, opposite, amplexicaule leaves; and wheel-shaped, deeply, five-parted, yellow flowers, in whorls at the upper parts, appearing very ornamental in July and August: it is also a valuable medical plant, and the root is the useful part.

The flowers or corolla of all these plants is of one tubular petal, more or less divided into four or five parts. See the *Characters*.

The plants are all perennial in root, but annual in stalk, which rise in spring, flower in summer, produce abundance of seed in autumn, and soon after die to the ground.

All the species, considered as flowery plants are very ornamental, the low sorts are elegant furniture for the fronts of borders and other flower compartments, and the large yellow kind should be stationed more backward, among the taller class of plants, where it will exhibit a noble appearance; and as all the sorts prosper in any common soil, affording plenty of seed for propagation, several of them also encrease by off-sets, they may be obtained plentifully in every garden.

All the sorts are easily raised from seed in the full ground, the first three sorts also by off-sets from the roots.

By seed.—Sow the seed in autumn, soon after they are ripe, or early in spring, in a bed or border of light rich ground, either by broad-cast on the surface, and rake it in lightly, or in shallow flat drills six inches asunder, covering it near half an inch deep; the plants will rise in April or May, give moderate watering in dry weather, and clear out weeds; and in summer, and towards autumn, prick out a quantity of the best into beds, in rows six inches asunder, where let them remain a year to gather strength, then in autumn or spring transplant them into the places where they are to remain to flower.

By roots.—The first three species encrease by off-sets of the roots in tolerable plenty, and

autumn, winter, or spring is the time to separate or divide them, and the slips or off-sets, if small, may either be planted in nursery-beds for a year, or, if not divided too small, may place them at once in the flower compartments.

GENUS, a fraternity, race, or kind; being an assemblage of different species of plants, resembling each other in the flower and fruit, or parts of fructification.

The characteristical mark of every Genus is the whole of the flower or fructification, and all plants agreeing exactly therein, are species of the same family or Genus; a Genus therefore, may in some measure be compared to a family, all the relations of which bear the same surname, although every individual is distinguished by a particular specific name; and that by arranging under one generic name, a collection of different species of plants, which although often ultimately different in their general growth, external port or habit, yet are all found invariably to possess certain relations in the generical characters of their essential parts, the fructification or flower and fruit, that declare them all plants of the same family or Genus.

A Genus of plants therefore, however numerous the species, and different in their general growth, external habit, and duration, are such as agree in all the parts of the flower, which being the only generical characters, a principle now universally established by the Linnæan botany, in no case to be departed from. See CHARACTERS. For the *characters* of every Genera or Genus contains a description of each particular part of the flower, as the *Calix*, *Corolla*, *Stamina*, *Pistillum*, *Pericarpium*, *Semen*, and *Receptaculum*; which being the seven parts of fructification, and the most essential and invariable parts of plants, and consequently the only parts that can determine the generical characters; and the striking singular mark of each of the above parts of the flower, must run through all the species of each respective Genus, according to the descriptive *characters* in the beginning of every Genus throughout this work; whereby, as afore-mentioned, every such assemblage of plants, however few or numerous, so agreeing in their fructification, form a Genus.

By arranging every assemblage of plants agreeing in their fructification, under one denomination or generical name, renders botany more simple and easy, which by the ancients was but little understood; as with them, al-

most every species was a Genus, and they had no conception of giving one common or general name to a number of plants, which although agreeing in their flower, they could, not discover possessed any thing in common; for the minute parts of the fructification which lay the foundation of our present systems, were then but little known, and as little attended to, as in fact the root: port or external habit of plants, their duration, mode, and times of flowering, and their uses, both medicinal and oeconomical, formerly furnished the sole characteristical distinction, all of which however, are vague and indeterminate; but as the fructification is constantly the same in every respective Genera, nothing but these parts can with certainty be employed in determining each separate Genus.

Plants and trees of the same Genus generally possess like medicinal powers. As for example, garlick, onion, and leek, belong to the Genus *allium*; cinnamon, camphire, and saffras belong to the Genus *laurus*; southernwood, wormwood, mugwort, &c. belong to the Genus *artemisia*.

Trees which belong to the same Genus, will also all take by grafting or budding upon each other: as for instance; pear, apple, and quince, being all of the Genus *pyrus*, take freely upon one another; plum, apricot, cherry, and bird-cherry, &c. being all of the Genus *prunus* also, grow upon stocks of each other; almond, peach, and nectarine belong to the Genus *amygdalus*, and grow upon one another; currant and gooseberry belong to the Genus *ribes*, and all the varieties will grow upon each other; as will also most other trees of the same Genus.

The number of known Genera is upwards of twelve hundred, and above twenty-thousand different species, besides varieties; all of which are found growing in their natural state of wildness in some part of the globe or other, and most of them may be naturalized in our gardens, some in the open ground, others in the green-house and stove; but the gardener is not to be intimidated at the sight of that great number, as if the care of so great a family was to fall to his lot; since our real valuable cultivated species fall vastly short of that number, yet sufficient to furnish our gardens most amply, both for oeconomical and ornamental purposes.

GERANIUM, Crane's-bill, but commonly called *Geranium*.

It comprizes herbaceous and shrubby plants

for the pleasure-ground and green-house, obtaining different statures from one or two, to six or eight feet high, adorned with broad simple leaves, in some roundish, others heart-shaped and oval, some intire, and some divided, and clusters of small pentapetalous flowers.

Class and order, *Monadelphia Decandria*.

Characters.] CALIX, five oval permanent leaves. COROLLA, five oval, or else heart-shaped, spreading petals. STAMINA, ten monadelphous filaments alternately longer, and oblong versatile antheræ. PISTILLUM, a five-cornered germen, long permanent style, and five-reflexed stigmas. PERICARPIUM, a long fruit, shaped like a crane's beak or bill, is quinquelocular, and contains five seeds.

There are upwards of fifty species, and of which the following are the sorts principally cultivated in the British gardens.

Hardy herbaceous kinds.

¹GERANIUM, *Pratense*.

Meadow Crow-foot Geranium.] Geranium with many branchy stalks, two or three feet high, garnished with divided, target-shaped leaves of six or seven lobes, cut into many wing-like acute parts; and at the top of the stalks large blue flowers, two upon each foot-stalk.

Varieties.]—With white flowers—variegated flowers.

²GERANIUM *Sanguineum*.

Bloody Geranium.] Geranium with thick, fleshy, fibrey roots; weak, branchy stalks, a foot or more high, garnished with divided leaves of five-trifid lobes; and deep red or purple flowers from the side of the branches, one upon each foot-stalk.

Varieties.]—With erect stalks—with deeply jagged leaves—and with variegated flowers.

³GERANIUM *Phæum*.

Black flowered Geranium.] Geranium, with upright, branchy stalks, ten or twelve inches high, divided leaves, of five or six lacinated lobes, and the branches terminated by blackish purple flowers, two upon each foot-stalk.

⁴GERANIUM *Nodosum*.

Knotty Geranium.] Geranium, with jointed, branchy stalks, six or eight inches high, garnished with divided leaves of three serrated lobes, those below having foot-stalks, the upper ones sit close, and at the ends of the branches, pale purple flowers by twos upon each foot-stalk.

⁵GERANIUM *Macrorrhizum*.

Long-rooted, Sweet-smelling Geranium.] Geranium, with a long thick fleshy root; branchy stalks

stalks a foot high, garnished with five-lobed, smooth leaves, the lobes divided into many short crenated segments, and the branches terminated by bunches of purple flowers, two upon each foot-stalk, and with inflated or bladder-like cups, and very long style.

⁶*GERANIUM Striatum.*

Striated Geranium.] Geranium with many branchy stalks near two feet high, garnished with five-lobed leaves below, and three-lobed ones above, and white flowers beautifully striated with purple, two upon each foot-stalk.

The above six species are very hardy fibrous perennials, durable in root, but annual in stalks, &c. which rise from the root in spring; flower in May, June, and July, producing a great profusion of flowers, each composed of five smallish spreading petals. See the *Characters*: and their numbers renders them very conspicuous, and are succeeded by plenty of seed in August and September, which if permitted to scatter on the ground, a crop of young plants will naturally rise in abundance.

Several of them grow naturally in many parts of England, particularly the first, second, third, and fourth sorts; the others are chiefly of foreign growth.

All the sorts prosper in any common soil of a garden.

They may all be employed as ornamental plants for the embellishment of the different compartments of the pleasure-ground, and to encrease the variety of the herbaceous collection; and as to their culture, they require only the common care of keeping clean from weeds, cutting down their decayed stalks, and digging between them annually in autumn, or any time in winter or spring.

They may all be propagated plentifully by seed, and by parting their roots.

By Seed.—Sow it in autumn soon after it is ripe, or in spring in a shady border, and rake it in lightly; when the young plants are about three inches high, prick them out in beds five or six inches asunder, giving occasional waterings, and in autumn or spring after, transplant them where they are to remain.

By Parting the Roots.—This may be performed any time from October till March, in open weather; do not divide them into too small slips; and may plant them at once where they are to remain.

Green-house Shrubby kinds.

⁷*GERANIUM Zonale.*

Zone-marked, or Horse-shoe Geranium.] Ge-

ranium with a shrubby stem, branching six or eight feet high, garnished with roundish heart-shaped, indented leaves, marked with a purple zonal circle, going quite round, in form of a horse-shoe; and from the upper parts of the branches, close bunches of reddish-purple flowers on very long foot-stalks.

Variety.]—Zone-marked Geranium, with elegantly variegated leaves, of singular beauty.

Both these varieties of this species are the sorts of *Geranium* the most commonly cultivated in our gardens, and are both very floriferous most part of summer; but the variegated sort is singularly ornamental at all seasons with its variegated white and green leaves.

⁸*GERANIUM Capitatum.*

Capitated Rose-scented Geranium.] Geranium, with a shrubby stalk branching irregularly four or five feet high; roundish, unequally trilobated, waved, hairy leaves, smelling like dried roses; and purplish-blue flowers in a capitated corymbus at the ends of the branches.

⁹*GERANIUM Fulgidum.*

Fulgid or flaming red Geranium.] Geranium with a shrubby, fleshy stalk, branching a foot or two high, garnished with divided, three-lobed, smooth, light-green leaves cut on the edges, having the middle lobe largest; and flame-scarlet flowers in umbellate clusters from the sides of the branches.

¹⁰*GERANIUM Inquinans.*

Large Mallow-leaved Scarlet Geranium.] Geranium with a shrubby stem, branching erectly six or eight feet high, garnished with roundish kidney-shaped, thick, bright green leaves, hoary underneath; and bright scarlet flowers on long foot-stalks from the sides of the branches.

¹¹*GERANIUM Papilionaceum.*

Papilionaceous flowered Geranium.] Geranium with a shrubby stalk, branching six or seven feet high; large angular, sharp-pointed, rough leaves, upon long foot-stalks; and papilionaceous-shaped, finely variegated flowers, in loose bunches at the ends of the branches.

¹²*GERANIUM Cucullatum.*

Cucullated or hood-leaved Geranium.] Geranium with a shrubby stalk branching six or seven feet high; roundish, indented nervous leaves, hollow in the middle like a hood; and purplish blue flowers, in large loose bunches at the top of the branches.

Variety.]—With angular, hooded leaves.

¹³GERANIUM *Vitifolium*.

Vine-leaved, Balm-scented Geranium.] Geranium with a shrubby stalk, branching five or six feet high, ascending, lobated, downy leaves, and pale blue flowers in close bunches, on long foot-stalks from the axillas of the branches.

¹⁴GERANIUM *Gibbosum*.

Gibbous, or gouty-stalked Geranium, with Columbine leaves.] Geranium with a shrubby, fleshy stalk, gibbous, or swollen at the joints, branching three or four feet high; doubly pinnatifid, fleshy, smooth, opposite leaves; and dark purple flowers at the upper parts of the branches.

¹⁵GERANIUM *Carnosum*.

Carnose, or fleshy-stalked Geranium.] Geranium with a shrubby, very thick, fleshy-jointed stalk, branching two or three feet high; pinnatifid, lacinated, thinly-placed leaves; and whitish flowers at the top of the branches.

¹⁶GERANIUM *Betulinum*.

Birch-leaved Geranium.] Geranium with a shrubby stalk branching four or five feet high, oblong, oval, plane, unequally-sawed leaves, and large reddish flowers from the sides of the branches.

¹⁷GERANIUM *Peltatum*.

Peltated, or Shield-leaved Geranium.] Geranium with slender, weak, shrubby stalks, branching two or three feet long; peltated, divided, fleshy, smooth leaves, of five entire lobes; and purple flowers by fours or fives, from the sides of the branches.

¹⁸GERANIUM *Acetosum*.

Sorrel-tasted Geranium.] Geranium with a shrubby stalk, branching five or six feet high; oval, fleshy, smooth leaves, tasting like sorrel; and bluish-coloured red-striped flowers, by threes or fours, from the sides of the branches.

Variety.]—With scarlet flowers.

All these shrubby *Geraniums* are beautiful ever-greens, being furnished with leaves all the year, and most of them very floriferous in summer, flowering principally in May, June, and July, though several of the sorts continue a succession of flowers during most of the summer months, even often until winter. They are mostly free shooters, and some of them shoot luxuriantly, especially when potted in rich, loamy earth; and the shoots of most of them are rather somewhat succulent, and of an herbaceous nature the first season of their growth, but become more woody as they advance in age: their leaves are mostly of an

orbicularly roundish figure, notwithstanding those of some sorts are divided into lobes, and are from about two to four inches broad, and mostly foot-stalked: the flowers are quinquepetalous, and separately are rather small, but being generally produced in clusters, are very conspicuous and ornamental; and in several of the sorts are succeeded by seeds, which falling in the pots, sometimes many young plants rise naturally.

They being all natives originally of Africa, are of tender quality; and in their culture here, must always be retained in pots, for moving to the shelter of a green-house, &c. in winter, for they will not live here in the open air during that season: they however only require protection from frost, and being free-shooters, should have as much free air as possible in open weather, therefore in winter, when placed in the green-house, should always be stationed towards the front next the windows.

All the sorts are beautiful furniture for the green-house collection, and those with variegated leaves exhibit a delightful contrast with all the others; and as all of them may be raised abundantly by seed and cuttings, in the common ground, they may be obtained plentifully in every garden.

The propagation of all these shrubby sorts, may be effected abundantly by seed, and by cuttings of their branches, though, as they all grow very freely by cuttings, they are most commonly propagated by that method; and both methods of propagation may be effected either in the natural ground, or by aid of hot-beds, to bring them more forward.

By Seed.—In April the seed may be sowed either in a bed of light rich earth a quarter of an inch deep, or in pots or boxes of the same soil, and the plants will come up in six weeks; but to forward their growth as much as possible, to be strong before winter, it is more adviseable to sow in a hot-bed, that is, in March or April sow it in pots, and plunge them in any hot-bed under glasses, and when the plants are two inches high, prick them into separate pots, which if plunged also in a hot-bed, will greatly forward the seedlings, giving occasional waterings, and shade till rooted, and in June harden them by degrees to the full air.

By Cuttings.—These may be planted in the full ground any time in May, June, and July; or to have them more forward, may plant some in pots in March or April, and plunge in a hot-bed; in either case take off the

the cuttings with a knife, from about four or five to eight or ten inches long, trimming off the leaves from the body of each cutting; observing, if the top is very soft and herbaceous, it may be shortened down to the firm wood, but when robust and firm, leave it intire; they may be planted either in the full ground in a shady border if in summer, or in pots placed in the shade, or as above observed, may plant them in pots in March, April, or May, and plunged in a hot-bed; or for want of this, may plant them in pots at the time just mentioned, and retain them in the green-house till May or June: in either mode of planting, put the cuttings two parts out of three into the ground, give a little water directly, and repeat it occasionally, and the cuttings will soon emit roots at bottom, and shoots at top, and be fit to transplant into separate pots in two or three months.

But the most expeditious way of raising them by cuttings, to have strong plants by winter, is to forward them in a hot-bed; planting the cuttings in pots, several in each; in March, April, or May, as above hinted, plunge them either in a dung hot-bed, or in a bark-bed in the hot-house, &c. they will quickly take root, and shoot at top, when they should be planted out into separate pots, and in June inure them gradually to the full air, and they will branch out at top and make fine plants by October.

With respect to their general culture, observe as follows:

They prosper in any light rich earth, but grow the most luxuriant in a moderate loamy soil; though in a light mold, as they shoot moderately, are more profuse in flowers.

They, as before noticed, must always be retained in pots for moving to shelter in winter, and into the full air in summer; in summer therefore, about the middle or latter end of May place them in the open air till October, observing to give frequent waterings in dry weather, which, in a very hot dry time, will be requisite almost every day. Towards the latter end of October remove them into the green-house to remain until May, placing them rather towards the front next the windows, in order to have as much free air as possible, otherwise they will be apt to draw up weak, and sometimes the young shoots will mould and root off, especially if they are much crowded. During their residence here give moderate watering once a week, or ten,

or twelve days, as you shall see necessary, and as the spring and warm weather advances, give more in proportion; giving it always in moderation whilst they remain in the green-house, especially the fleshy or more succulent kinds, which are apt to take a mouldiness, and rot with redundant moisture, or very damp air at this season; and with respect to fresh air, they of course will have it in common with the other exotics of the same department. See GREEN-HOUSE PLANTS. Keep all decayed leaves constantly picked off, being necessary to the health and beauty of the plants; they being very fast growers, should be shifted every year at least, into larger pots; the proper season, April and May, being careful to remove them with the balls of earth about their roots, paring off the outside matted fibres, and clear off also some of the old earth all around; and so pot them again directly in some fresh mould, filling up around the ball, and about an inch in depth over its top, with the same new soil.

Green-house herbaceous kinds.

¹⁹GERANIUM *Alchimilloides*.

Ladies Mantle-leaved Geranium.] Geranium with herbaceous trailing stalks a foot and half long; roundish, palmated, hairy leaves, the edges cut into many parts; and whitish flowers in clusters most part of summer.

Varieties.]—With a dark circle in the middle of the leaves—and with blueish flowers.

²⁰GERANIUM *Odoratissimum*.

Odoriferous, or Sweet-scented Geranium.] Geranium with an herbaceous, short, fleshy stalk, dividing into several short branchy-heads, garnished with heart-shaped, soft, downy leaves strongly scented, and many small white flowers by fours or fives, appearing most part of summer.

²¹GERANIUM *Grossularoides*.

Gooseberry-leaved Geranium.] Geranium, with herbaceous, prostrate stalks, branching a foot and half long; small, roundish, heart-shaped, crenated leaves; and reddish flowers on short foot-stalks from the sides of the branches.

²²GERANIUM *Triste*.

Dark-spotted night-smelling Geranium.] Geranium with a thick tuberous root, crowned by pinnatifid, finely divided, prostrate leaves; and among them arise bifid, naked, flower-stalks, terminated by bunches of yellowish dark-spotted flowers, smelling sweet in the evening.

²³GERANIUM

¹³GERANIUM *Prolificum*.

Prolific or Variable Geranium.] Of which there are several varieties.—With thick tuberous roots, of different shapes, crowned with leaves; also of various forms in the varieties, and among them, the flower-stalks directly from the root, terminated by compound umbels of flowers, which in the different sorts, are red, crimson, purple, white, &c.

Varieties of this are:

Pinnated Prolific Geranium.—Having leaves divided in the pinnated manner, in some into oval lobes, others into long narrow parts.

Auriculated Prolific Geranium.—Having oblong, and sometimes three-parted leaves, auriculated or eared at each side of the base.

Long-leaved Prolific Geranium.—Having very long spear-shaped leaves.

Fleshy-leaved Prolific Geranium.—Having oval hastated fleshy leaves.

²⁴GERANIUM *Lobatum*.

Lobated Geranium.] Geranium with a roundish, large, fleshy root, crowned with lobated, hairy crenated leaves, shaped like those of vines; and between them naked, truncated flower-stalks a foot high, terminated by umbellate clusters of red, and in some sorts white flowers.

Varieties.]—With pinnatifid leaves—with lacinated leaves.

All these tender herbaceous *Geraniums*, being natives of Africa, as observed of the shrubby kinds, must always be kept in pots, to move to shelter in winter. They grow freely in any light rich garden earth, and may be preserved through the winter either in a greenhouse or garden-frame, under occasional shelter of the glass lights.

All the tuberous-rooted kinds are remarkably fine scented in the night, hence are denominated *Geranium Noctuo-olens*, or night-smelling Geranium.

They may be propagated by seed sowed in spring, in pots of light earth, and placed in a hot bed, as directed for the shrubby sorts; they may also be propagated by slipping their roots in August or September, or early in spring, which, of the tuberous kind, every slip of the tubers having an eye or bud, will readily grow.

GERMEN, the seed-bud, i. e. the base of the pistillum, is situated in the bottom of the flower, and contains the rudiments of the seed, and in progress of vegetation swells, and becomes the seed-vessel.

The Germen in all plants is situated in the

bottom of the flower; in some however, within the corolla, and in others, under its base, and which always supports the style and stigma, the female organs of generation, whereby modern botanists denominate the seed-bud or Germen, the *Ovarium* or *Uterus* of plants, which, after its impregnation by the male dust of the antheræ or male organ falling upon the stigma, it becomes a seed-vessel, gradually ripening to maturity, together with the seeds contained therein.

GERMINATIO, the Germination or sprouting of seeds, after being committed to the earth.

Different sorts of seeds are longer or shorter in germinating, and rising according to their nature and heat requisite for each; several of the grasses often rise in one day; cresses, mustard, radish, rape, and turnip, in from three to six or eight days; cucumber, melon, gourd, cabbage, favoy, cauliflower, broccoli, beet, spinach, lettuce, purslane, dill, orach, bean, kidney-bean, pea, &c. in from about three or four, to ten or fifteen days; onion, leek, carrot, parsnip, celery, in from about ten or twelve, to eighteen or twenty days; parsley, from about fifteen or twenty, to forty or fifty days; hawthorn, medlar, and several other hard, bony seed, and nuts, are often two years before they germinate; and some of the liliaceous plants never rise at all; observing, that in respect to the above observations of the germination of seed, it is principally to be understood of seeds sown in spring and summer, and the more advanced and warm the season, the sooner may the seed be expected to rise.

Seeds also preserve their germinating property shorter or longer according to their kinds; some do not retain it scarcely a year, others for a series of years; particularly many of the papilionaceous tribe: and it is asserted, that the sensitive plant retains its germinating faculty for thirty or forty years.

Most seeds germinate the most freely when sowed in spring and summer; some however require to be sown in autumn, soon after they are ripe, otherwise they will not sprout in less than a year or two, which sorts are always hinted in the course of the work, under their respective articles.

As air and moisture are the agents of vegetation, it is for want of air that seeds which are buried at a very great depth in the earth, either rise but indifferently or not at all; they frequently however preserve their germinating

nating property for many years within the bowels of the earth, and it is not unusual upon a piece of ground being dug up to a considerable depth, to see it covered with several plants, which probably have not been seen there in the memory of man. Seeds will also retain their vegetative virtue for years in the bottom of wells, ditches, ponds, &c. which when cleaned out, and the mud exposed to the air, various sorts of plants have risen therein, that had not appeared thereabouts for a great number of years, by which circumstances certain species of plants regarded as lost, have been accidentally recovered.

GEUM, Avens, or Herb-bennet.

The plants are hardy, herbaceous perennials for the pleasure-ground, rising with annual stalks about a foot high, terminated by pentapetalous flowers.

Class and Order, *Icosandria Polygynia*.

Characters] CALIX, is monophyllous, cut into ten segments alternately smaller. COROLLA, five roundish petals, long and narrow toward the base. STAMINA, numerous filaments, and broad obtuse antheræ. PISTILLUM, numerous germina collected into a head, and many long, hairy styles, and simple stigmas—PERICARPIUM, none, numerous seeds sitting on the oblong receptacle placed on the calix.

The principal species are ;

¹GEUM Urbanum.

Common Avens or Herb-bennet.] Geum with thick, fibrey, aromatic roots, crowned by large, lyre shaped, rough, serrated leaves, and upright, round, hairy stalks, a foot high, terminated by largish yellow flowers, succeeded by globular fruit.

This grows wild in woods and by hedges in England, &c. the root is used in medicine, and the young leaves often as a pot-herb.

²GEUM Rivale.

Water-nodding-flowered Avens.] Geum, with a thick, fleshy, very fibrey root, crowned with large lyrated, hairy leaves, and upright stalks ten or twelve inches high, terminated by purple flowers nodding on one side.

Varieties.]—With red flowers—large yellow flowers.

³GEUM Virginianum.

Virginian Avens.] Geum with upright stalks a foot and half high, ternate leaves below, those above simple, and the stalks terminated by small white flowers.

⁴GEUM Montanum.

Mountain Avens of the Alps.] Geum with a thick, fleshy, fibrated, creeping root, crowned with leaves composed of several small irregular lobes, terminated by a broad roundish one, and slender stalks near a foot high, garnished with narrow sharp-pointed leaves, and terminated by erect yellow flowers.

Variety.]—Dwarf Alpine Avens, with a large golden flower.

All these plants have perennial roots and annual stalks, which rise in spring, flower in May and June, and ripen seeds in July and August. The plants are hardy, and succeed almost any where.

They may be introduced in the pleasure-ground here and there towards the fronts of the flower and shrubbery compartments, to encrease the variety.

Their propagation is both by seed, and by parting the roots. Sow the seed in September in a bed or border, and the plants will rise in spring. By parting the roots, it may be done any time, in open weather, from September till March.

GLADIOLUS, Gladiole, Sword-lily, or Corn-flag.

The plants are tuberous-rooted, herbaceous, flowery perennials, of the liliaceous tribe, for the pleasure-garden, having sword-shaped leaves, and erect annual stalks two feet high, adorned with hexapetalous, lily-like flowers.

Class and order, *Triandria Monogynia*.

Characters.] CALIX, a spatha to each flower. COROLLA, six oblong petals united at their base, the three upper ones incline to each other, and the under ones spread open. STAMINA, three filaments, inserted into every other petal, and oblong antheræ. PISTILLUM, a germen under the corolla, single style, and trifid concave stigma. PERICARPIUM, an oblong, ventricose, trigonal, trilocular capsule, and roundish seeds.

There is but one hardy species common to the English gardens, out of which are many eminent varieties.

GLADIOLUS Communis.

Common Gladiole.] Gladiolus with a round, compressed, tuberous, bulb-like root, sending up long sword shaped leaves, embracing each other at the base, between them an erect flower-stalk two or three feet high, the top garnished with several largish flowers at a distance, of different colours in the varieties, and in some ranged all on one side of the stalk, and in others in two ranges, &c.

Varieties.]

Varieties.]—Common red Gladiolus, with flowers ranged on one side of the stalk—purple flowers on one side of the stalk—white flowers on one side of the stalk—crimson flowers on one side of the stalk—red flowers ranged in a double series—white flowers in a double series—broad-leaved, tall Gladiolus, with large purple flowers—broad leaves, and large crimson flowers. All of which are varieties of one species, as the seed saved from one plant often produces them all. They all flower in the end of May, and in June are very conspicuous and ornamental, and are succeeded by plenty of seed in August, and their stalks and leaves decay soon after; the flowers are moderately large, each of six petals. See the *Characters*.

The plants are very hardy, and will flourish almost any where, and encrease greatly by their roots, especially the common red sort, so as often to become troublesome.

They are proper furniture for the common flower borders, &c. intermixed with other perennials of similar growth, where they will exhibit a very fine appearance when in flower.

The roots are sold at the nurseries and seed-shop, and the time to plant them is September, October, and November. They should be taken up every two or three years at the decay of the leaves, to separate the off-sets, &c.

All the varieties are propagated plentifully by off-sets from the roots, which they emit in abundance every year like tulips and other bulbs. July and the beginning of August, when the stalks and leaves decay, is the time to take up the roots to separate the off-sets, or transplant the roots from one place to another; though if taken up at the proper time, they may be kept out of the ground till October or November, or longer if necessary.

They may also be propagated by seed. Sow it in autumn in a bed or border of light earth, the plants will come up in the spring, and when their leaves decay in summer, transplant them into nursery-beds to remain a year or two, till of due size to flower; then transplant them where they are to remain.

GLEDITSIA, Triple-thorned Acacia.

There is but one species, a large deciduous tree for ornamental plantations, adorned with beautiful pinnated foliage, and amentaceous male and hermaphrodite flowers on the same plant, and females on separate trees.

Class and order, *Polygamia Dioecia*.

Characters.] **CALIX**, male flowers col-

lected in a long compact cylindric katkin, terminated by the hermaphrodites, each having a three-leaved cup, and female flowers on separate plants, having a five-parted calix. **COROLLA**, three roundish petals in the males and hermaphrodites, and five long acute ones to the females. **STAMINA**, six filaments and oblong antheræ. **PISTILLUM**, a broad germen longer than the corolla, short reflexed style, and thick stigma. **PERICARPIUM**, a large flat pod, having transverse partitions, each division replete with pulp, and one hard round seed.

The species is;

GLEDITSIA *Triacanthos*.

Triple-thorned Acacia.] **Gleditsia**, with an upright trunk, rising thirty or forty feet high, branching out regularly, and having the stem and branches armed with many long triple thorns, and closely garnished with doubly pinnated leaves, each leaf consisting often of near two hundred smaller leaves or foliola; and amentaceous greenish flowers from the sides of the branches, succeeded by broad seed-pods near a foot and half long.

Variety. With fewer thorns, smaller leaves, and oval pods.

These trees have singular beauty in summer, when clothed with their large, long, pinnated foliage, which spread open delightfully in fine weather, but rather droop and contract at the approach of bad. They flower in July, but being of an herbaceous colour, make but little appearance; but their large seed-pods have a fine effect, though these do not often attain perfection in England.

They are natives originally of America, but grow freely here in any situation.

Both the varieties are fine furniture for all ornamental plantations and shrubbery-work, &c. and have an admirable effect placed singly in large opens of grass ground.

Propagation.

Their propagation is by seeds, which are annually procured from America by the seedsmen: sow them in spring in a warm border of light earth half an inch deep, giving occasional waterings in dry weather, and the plants will rise the same season, and by spring following, the largest will be fit to transplant, and in spring after all the rest, planting them in nursery-rows, one foot by two asunder, to remain till a yard or two high.

GLOBULARIA, Globular blue Daisy.

The plants are herbaceous, flowery perennials,

G L O

nials, producing annual stalks from about six, to ten, or twelve inches high, surmounted by globular heads of blue flowers.

Class and order, *Tetrandria Monogynia*.

Characters.] CALIX, a general cup, containing many florets, each having a monophyllous cup, five-parted at top. COROLLA, the general flower consists of many florets collected into a globular head, each floret is monopetalous, tubular, and five-parted at the brim. STAMINA, four filaments, and incumbent antheræ. PISTILLUM, an oval germen, single style, and obtuse stigma. PERICARPIUM, none, one seed to each floret, lodged in its calix.

There is but one species common to our gardens, viz.

GLOBULARIA Vulgaris.

Common Globularia.] Globularia, with broad, thick, radical leaves, three-parted at the ends; upright stalks from about six, to ten, or twelve inches high, garnished with spear-shaped leaves; and the top crowned by a globular head of fine blue flowers, composed of many florets in one general cup. See the *Characters*.

It flowers in June, and makes a good appearance towards the fronts of the flower-borders, but flowers best in a shady moist situation.

The propagation is effected by parting the roots in September.

GLORIOSA, Superb Lily.

It is a tender, herbaceous, flowering perennial for the stove, producing trailing, annual stalks several feet long and hexapetalous liliaceous flowers.

Class and order, *Hexandria Monogynia*.

Characters.] CALIX, none. COROLLA, six oblong, spear-shaped, waved, extremely long petals, wholly reflexed back. STAMINA, six spreading filaments, and incumbent antheræ. PISTILLUM, a globular germen, slender inclined style, and triple stigma. PERICARPIUM, an oval, trilocular capsule, and many globular seeds.

There is but one species, viz.

GLORIOSA Superba.

Superb Lily.] Gloriosa, with a thick, fleshy, tuberous root; sending forth from its centre declinated round stalks, growing eight or ten feet long, garnished with very long, narrow leaves, running out to a point, terminated by a long tendril; and from the upper part of the stalks, large flame-coloured drooping flowers of six widely spreading reflexed petals.

G L Y

It flowers in June and July, and is of admirable beauty, hence it derives the name *Gloriosa*, or Superb Lily.

This plant being a native of Ceylon and Malabar, very warm countries, requires the protection of the hot-house here, so must be kept in pots of light earth, and placed constantly in that department. The flower-stalks shoot forth in March or April, which being long, and of trailing growth, must have tall sticks placed for their support: water them frequently in summer during their growth, but give very little after their flowers and stalks decay.

The time for removing the roots either for encrease, or to transplant into fresh earth, &c. is, in autumn, when their stalks decay, or early in spring before they begin to shoot.

It is propagated by off-sets of the roots, which they yield in tolerable plenty, and may be separated any time after the stalks decay, or in spring before new ones arise.

GLYCINE, knobbed rooted Liquorice Vetch.

Of this Genus, is one shrubby climber, usually cultivated for the shrubbery, adorned with noble pinnated foliage, and fine papilionaceous blue flowers.

Class and order, *Diadelphia Decandria*.

Characters.] CALIX, is monophyllous and bilabiated. COROLLA, is papilionaceous, having a heart-shaped vexillum, small, oblong, oval wings; and narrow sickle-shaped keel. STAMINA, ten diadelphous filaments, and single antheræ. PISTILLUM, an oblong, germen, spiral style, and obtuse stigma. PERICARPIUM, an oblong pod, and kidney-shaped seed.

The species commonly cultivated in our gardens is;

GLYCINE Fruticens.

Shrubby Glycine, commonly called Carolina Kidney-bean-tree.] Glycine, with shrubby climbing stalks twining round any support, fifteen or twenty feet high, adorned with pinnated leaves of three pair of folioles, terminated by an odd one, and from the axillas, clusters of large blueish-purple flowers, succeeded by long pods, like those of the climbing kidney-beans.

It flowers in July and August, but the seeds do not ripen here.

This is an elegant shrubby climber, ornamental both in foliage and flowers, and merit a place in the best shrubberies.

It is easily propagated by seed, and by layers.

H h h

By

By Seed. This is imported annually from America. Sow it in spring in a bed of light earth, half an inch deep; give the young plants occasional protection of mats from frost the following winter; in spring plant out some of the largest in nursery rows, and in spring after put out the remainder.

By Layers. In autumn lay down the young shoots in the earth, and by that time twelve-month they will be rooted and fit to transplant.

GLYCYRRHIZA, Liquorice.

This genus furnishes one valuable herbaceous perennial for medical use, producing annual stalks a yard or more high, pinnated leaves, and papilionaceous flowers.

Class and order, *Diadelphia Decandria*.

Characters.] **CALIX**, is monophylous, tubular, and bilabiated. **COROLLA**, is papilionaceous, having a long, erect vexillum, oblong wings, and dipetalous carina. **STAMINA**, ten diadelphous filaments, and roundish antheræ. **PISTILLUM**, a short germen, slender style, and rising obtuse stigma. **PERICARPIUM**, an oval or oblong pod, and kidney-shaped seed.

¹**GLYCYRRHIZA, Glabra.**

Smooth-podded Glycyrrhiza, or Common Liquorice.] Glycyrrhiza, with a long, thick, creeping root, striking several feet deep into the ground; upright, firm, herbaceous stalks annually, three or four feet high, garnished with winged leaves of four or five pair of oval lobes, terminated by an odd one; and from the axillas erect spikes of pale blue flowers in July, succeeded by short smooth pods.

The root of this is the useful part, which is replete with a sweet, balsamic, pectoral juice, much used in all compositions for coughs and disorders of the stomach.

²**GLYCYRRHIZA, Echinata.**

Echinated or Prickly-podded Liquorice.] It is nearly like the common sort, only the seed-pods are prickly.

Both these species are very hardy perennials, but the first species is the sort commonly cultivated for use, its roots being fuller of juice and sweeter than the other.

The roots are perennial, but the stalks rise in spring, and decay in autumn.

They delight in a deep light soil, in which the roots will run down three or four feet deep, and attain a large size if permitted to stand three or four years; and from the main root smaller ones run off horizontally, and from these horizontal roots, that run near the

surface, cuttings for sets or young plants are taken for propagation, which are generally procured at the time when the Liquorice is taken up for use, being fit in three years after planting.

Where large quantities are required for sale, they may be cultivated in fields, as practised in many parts of England; vast quantities are also raised in the kitchen-gardens about London, where, by the richness and depth of the ground, the roots attain their utmost perfection in length and bulk.

The length and thickness of the roots is a principal consideration to the planter, as they are always sold by weight.

Propagation and Culture.

Their propagation is, as above observed, effected by cuttings of the small roots issuing from the sides of the main ones, near the surface of the earth, dividing them into lengths of six or eight inches, each having one or more good buds or eyes; and the proper season for procuring the sets for planting is, any time, in open weather, from October till March, though from the middle of February, till the middle of March, is rather the most successful season for planting.

An open situation is the most suitable for a plantation of these plants.

Particular regard should also be had to the soil; it ought to be of a light, loose temperature, and three or four feet deep if possible, for the roots of the Liquorice will arrive at that depth and more, and the longer the roots the more valuable they are for sale by weight.

Having fixed on the ground, let it be trenched three spades deep, if the depth of proper soil will admit, then having your sets ready, proceed to plant them by line and dibble, planting the sets a foot distance in each row; putting them perpendicular into the ground, with the tops about an inch under the surface, and let the rows be a foot and half asunder; though the London gardeners seldom allow more than twelve inches between row and row; these gardeners also sow a crop of onions on the same ground the first year, which, as the onions root but slender, and spread but little at top, may be done without any detriment to the Liquorice, nor that to the onions, as it does not rise above ten or twelve inches high the first summer; observing to keep the ground clean from weeds during that season by hoeing; and if there is a crop of onions, use the small hoe, cutting

cutting out the onions to four or five inches distance, clearing away such as grow immediately close to the Liquorice plants; and when the onions are gathered, give the ground a thorough hoeing with a large hoe, to loosen the surface and destroy all weeds effectually; and in autumn cut down the decayed stalks of the Liquorice, and nothing more is necessary to be done till spring; when, in February or March give a slight digging between the rows, and during spring and summer, keep down all weeds by broad-hoeing; and in autumn when the stalks are in a decaying state, cut them down to the surface of the earth as before observed. The same work is to be repeated every succeeding year: that is, slightly stir the ground in spring, keeping down all weeds in summer in hoeing, but after the first or second year, the stalks of the Liquorice will shoot strongly, and soon cover the ground, so as greatly to retard the growth of weeds.

Likewise, every autumn, about October, when the stalks begin to decay cut them down to the ground and clear them off.

In three years after planting, the roots of the Liquorice will be fit to take up, and the proper season for this is, any time from the beginning of November till February, for it should neither be taken up before the stalks are fully decayed, nor deferred till late in spring, otherwise the roots will be apt to shrivel and diminish in weight.

The method of taking it up is by trenching the ground, beginning at one end, and open a trench close to the first row three or four spades deep, or to the depth of the roots, at which work three or four spademen are generally employed at each trench; one goes on with the top spit, a second with the next spit, another with a third spit, and the fourth spademan commonly gets to the bottom of the roots, having a mattock to assist him occasionally to clear them, so as he takes them up, throws them on the top of the undug ground; and in this manner proceed row and row, till the whole plantation is taken up.

The small side-roots are trimmed off, and the best divided into lengths for fresh sets, and the main roots are tied in bundles ready for sale.

It is of advantage to sell them as soon as possible after they are taken up, before they lose much of their weight.

They are sold to the druggists, from about twenty to thirty or forty shillings per hundred weight, and an acre of ground has produced three thousand and upwards, which has been

sold for more than sixty pounds, but the price is commonly in proportion to the goodness of the roots.

GNAPHALIUM, Cudweed, Goldylocks
Eternal-flower, Everlasting, &c.

This genus consists of herbaceous and small under-shrubby flowering perennials for the open ground and green-house, of different statures, from six or eight inches, to four or five feet, adorned mostly with white hoary leaves, and terminated by compound flowers in corymbose clusters, remarkable for retaining their beauty for years after being gathered.

Class and order, *Syngenesia Polygamia Superflua*.

Characters.] **CALIX**, compound flowers, having a roundish, imbricated, permanent, general cup. **COROLLA**, many hermaphrodite and female florets in one general cup, the females have no petals. **STAMINA**, five filaments, and cylindric antheræ. **PISTILLUM**, an oval germen, filiform style, and bifid stigma. **PERICARPIUM**, none: the calix is permanent and glossy; and the seeds are single under each floret, and crowned with down.

The most material species in the English gardens, are the following three hardy, and three tender kinds.

Hardy Kinds.

¹**GNAPHALIUM**, *Margaritaceum*.

Pearly-white Eternal-flower.] **Gnaphalium** with creeping, very spreading roots, crowned with broad, spear-shaped, white, hoary leaves; herbaceous, thick, woolly stalks, a foot and half high, branching out upward, garnished with long, acute-pointed, white, woolly leaves placed alternate, and each branch terminated by a corymbose cluster of yellowish flowers, in large, prickly, white permanent cups appearing in June and July, are very ornamental; and which if gathered in a dry day soon after they appear, they will retain their beauty some years, hence it is often called everlasting, or eternal flower.

This spreads and multiplies exceedingly by its creeping roots.

²**GNAPHALIUM**, *Plantaginifolium*.

Plantain-leaved Cudweed.] **Gnaphalium**, with large oval, woolly, radical leaves; decumbent, running shoots rooting in the ground, and herbaceous, simple stalks six or eight inches high, terminated by a corymbus of white flowers in June, July, &c.

This also multiplies greatly by its off-set-runners rooting in the earth.

³GNAPHALIUM, *Stæchas*.

Narrow-leaved Stæchas.] Gnaphalium, with a shrubby stalk, branching into long, slender stalks three feet high, covered with a white bark, narrow leaves, hoary underneath, and all the branches terminated by compound corymbose clusters of yellow flowers appearing from May or June, to the end of summer, and which, if gathered dry, will continue some years.

*Tender Kinds.*⁴GNAPHALIUM, *Orientele*.

Oriental Goldy-locks, or Immortal Flower.] Of which there are the following *Varieties*.

Dwarf Oriental Goldy-locks.—Hath a short, shrubby stalk, a few inches high, branching out into many heads, garnished with narrow, woolly leaves, and from the heads, flower-stalks six or eight inches long, terminated by a compound corymbus of golden yellow flowers.

Narrow-leaved, Oriental, Immortal Flower.—Hath shrubby stalks, branching two or three feet high, long, spear-shaped woolly leaves, and the branches terminated by a compound corymbus of golden yellow flowers—likewise a variety with silvery white flowers.

Broad-leaved Oriental Immortal Flower.—Hath broad, spear-shaped, white, woolly, radical leaves; woolly stalks branching a foot and half high, adorned with spear-shaped, woolly leaves; and the branches terminated by compound clusters of golden yellow flowers.

These three varieties of *Gnaphalium Orientele*, flower in May and June, and often continue in succession great part of summer; and if those of all the sorts are gathered before they are too ripe, in a dry day, they remain beautiful for many years; hence the name Immortal flower, &c.

⁵GNAPHALIUM, *Orodatisimum*.

Sweet-scented Eternal Flower.] Gnaphalium with shrubby-winged stalks, branching irregularly a yard high, oblong, blunt leaves hoary underneath, and decurrent, having a wing or border running along the stalk or branch, and the branches terminated by compound, close, corymbose clusters of bright gold-coloured flowers, changing to a dark yellow.

⁶GNAPHALIUM, *Arboreum*.

Tree Gnaphalium.] Gnaphalium, with a woody stem, branching four or five feet high, narrow sessile leaves, with revolute borders, smooth on their upper side, and roundish bunches of pale yellow flowers.

The flowers of all these species of *Gnapha-*

lium are compound, having many small florets, common to one general cup or calix, which is persistent, dry, and shining, (see the *Characters*) and generally all terminate the branches in a compound, compact corymbus, and all of which possess the singular property of retaining their beauty in their proper colours for several years, if kept dry and clean.

Most of the sorts come into flower about June, and continue great part of summer.

The first three sorts are hardy, and may be employed as plants of ornament, in any compartment of the pleasure ground, for they will thrive in any soil and situation; the two first of which encrease exceedingly by their roots, and rooting shoots, which may be taken off in autumn or spring, and planted where they are to remain; and the third sort being shrubby, is propagated by planting slips or cuttings of its shoots any time in spring or summer, in a shady border.

But the fourth, fifth, and sixth species are somewhat tender, and some should be kept in pots, to be sheltered in a green-house or garden-frame, in winter; others may be planted in the full ground in a warm, dry situation, especially the oriental kind, and varieties; also, the sweet-scented sort, for these two species will struggle tolerably through an ordinary winter, and make a pretty appearance during the summer months. All these being shrubby, are propagated by slips or cuttings of their shoots, any time in spring or summer; planted either in borders of natural earth, and covered with hand-glasses till rooted, or by planting them in pots, and place them in a hot-bed, which will bring them forwarder.

GOMPHRENA, *Globe Amaranthus*.

Of this genus there is one tender, very ornamental, annual, and varieties, of two or three feet stature, adorned with simple entire foliage, and globular heads of aggregate florets.

Class and order, Pentandria Digynia.

Characters.] CALIX, many florets, collected into a capitulum or head, each having a diphyllous, coloured, permanent cup. COROLLA, numerous, small, erect florets, collected into a close head; each floret five-parted at the brim, and has a five-parted nectarium. STAMINA, five scarce discernible filaments. PISTILLUM, in each floret an oval germen, two small styles, and simple stigmas. PERICARPIUM, a small roundish capsule, succeeding each floret, and one roundish seed.

The

G O M

The species is;

GOMPHRENA, *Globosa*.

Globosa Gomphrena, commonly called Globe Amaranthus.] Gomphrena, with an upright stalk, branching erectly all around, two or three feet high; the branches by pairs opposite, each pair crossing the other; garnished with oval-lanceolate, opposite leaves, and every branch and side-shoot, terminated by a close globular head of flowers, composed of numerous very small starry florets, closely covered with dry scaly calices, placed imbricatum, persistent, and beautifully coloured, and in which consists the beauty of the flowers, which are of different colours in the varieties.

Varieties are.] Globe amaranthus, with purple heads—with white or silvery heads—with red heads—with striped or variegated heads—with spiked heads.

All these varieties are very floriferous and ornamental, they divide into many branches, each of these sending forth many axillary foot-stalks, each supporting a round head of flowers, accompanied by two leaves, appearing from June till November, succeeded by plenty of ripe seeds.

They are tender plants of the annual tribe, rising from seed in spring, and totally perish at the approach of winter.

The flowers themselves are separately so small, and closely covered with the scaly calices, that they scarcely appear; so that the numerous, closely placed, scaly coverings, being of a dry, firm consistence, coloured and glittering, collected into a compact, round head, the size of an ordinary cherry, are very conspicuous, and make a very ornamental appearance.

These flowers, if gathered when at full growth, and placed out of the sun, will retain their beauty several months.

The plants being natives of India, are of tender quality here, requiring aid of artificial warmth to raise and forward them to a proper state of growth, so as to flower in perfection and produce ripe seed; therefore, they are raised in hot-beds under glasses in spring, and retained there till June, for they will not bear the open air here till the middle, or latter end of that month.

They are commonly cultivated in pots, and placed to adorn fore-courts, and other conspicuous compartments, in assemblage with other curious annuals, though they may also be planted out into the open borders, &c.

G O S

Propagation and Culture.

All the varieties are propagated only by seed sowed annually in March, or beginning of April, in hot-beds under glasses; as for *amaranthus*, and the *celosia cristata*, or *cocks-comb*.

The seeds being closely enveloped in their scaly, chaffy covering, it should be pulled to pieces and separated as well as possible, and having the hot-bed ready as directed for the *amaranthus* and other tender annuals, sow the seed either in the earth of the bed, covering it a quarter of an inch deep with fine mold, or may be sowed in pots, and plunge them in the hot-bed, as shall be convenient: the plants will come up in a week or ten days, and when they are an inch high, they should be pricked down either in the same bed, if of good heat, or in a fresh one, three or four inches distance, giving water, occasional shade, and fresh air. Here let them grow three weeks or a month, when they will be considerably increased in growth, and should be transplanted into another hot-bed, at six or eight inches distance, or may now plant them in pots, (thirty-twos) and plunge them in the hot-bed, under a deep frame, to draw them up tall, where they may grow till June, then shifted into larger pots, observing at each removal, to give water and shade occasionally till rooted, and give fresh air daily at the upper end of the lights; and frequent waterings, managing them in every respect as directed for the *amaranthus* and *cocks-comb*, and other tender annuals. See **ANNUAL PLANTS**. And in June innure them gradually to the full air, and if any are not potted, transplant them therein with balls about their roots; and towards the latter end of that month may remove them into the full air entirely, at which time also, if you intend to plant any in the borders, should then transplant them from the hot-bed with balls about their roots.

During summer, those in the pots should be watered three or four times a week in dry weather; towards August a pot or two of each variety for seed, should be placed in a frame or glass-case, to be occasionally sheltered from excessive wet and cold nights, whereby they will ripen the seeds more effectually.

GOSSYPIMUM, Cotton Plant.

This genus consists of some herbaceous annuals, and shrubby perennials of the stove, rising from two to five or six feet high, having divided leaves, and pentapetalous flowers, succeeded

succeeded by capsules filled with seeds, wrapped up in that fine downy matter called cotton.

Class and Order, *Monadelphia Polyandria*.

Characters.] CALIX, is double, the outer one large and half-trifid, the inner one cup-shaped, and indented at the brim. COROLLA, five heart-shaped, plane petals. STAMINA, numerous united filaments, and kidney-shaped antheræ. PISTILLUM, a roundish germen, a columnous style, and four thick stigmas. PERICARPIUM, a roundish, acuminate capsule, of three or four cells, filled with oval seeds, and fine down, called cotton.

The plants are cultivated in some of our hot-houses for curiosity, and for which a plant or two of a sort is sufficient.

The chief species are;

¹Gossypium, *Herbaceæ*.

Common herbaceous Cotton.] Gossypium, with an herbaceous, smooth stalk, two feet high, branching upwards; five-lobed smooth leaves, and yellow flowers from the ends of the branches, succeeded by roundish capsules full of seed and cotton.

²Gossypium, *Hirsutum*.

Hairy American Cotton.] Gossypium with hairy stalks branching laterally two or three feet high; palmated, three and five-lobed, hairy leaves, and yellow flowers, succeeded by large oval pods, furnished with seeds and cotton.

³Gossypium, *Barbadosense*.

Barbadoes Shrubby Cotton.] Gossypium, with a shrubby stalk, branching four or five feet high, three-lobed smooth leaves, glandulous underneath; and yellow flowers, succeeded by oval pods, containing seeds and cotton.

⁴Gossypium, *Arboreum*.

Tree Cotton.] Gossypium, with an upright woody perennial stalk, branching six or eight feet high; palmated, four or five-lobed, smooth leaves, and yellow flowers, succeeded by large pods filled with seeds and cotton.

The first three species are principally annual, rise from seed in spring, and perish root and stalk in autumn, more especially the first and second sorts.

But the fourth sort is perennial in root and stalk.

It is these plants which produce the cotton for use, and in warm countries they are cultivated in great quantities in fields, as we do corn, particularly the annual sorts; but the first species is the most commonly cultivated.

The pods are sometimes as large as middling

apples, closely filled with the cotton, surrounding the seed.

They are natives of the warm parts of America, so that if a plant or two of each is required here for variety, they must be raised and continued in the stove, where they will flower, and produce pods furnished with seeds and cotton.

Their propagation is by seed sown in pots of light earth in spring, plunging them in the bark-bed, and when the plants are an inch or two high, prick them in separate pots, which plunge also in the bark-bed, and retain them always in the stove.

GRAFTING, a mode of propagation, particularly used for most sorts of fruit-trees, being the only certain method to continue the approved varieties in their kind, and is also used for propagating many sorts of flowering-shrubs and timber-trees.

This mode of propagation is, the taking a graft or shoot of one tree, and inserting or ingrafting it into the stem or branch of another, and they both uniting as one, the graft shoots forth into branches and becomes the tree, producing flowers and fruit exactly the same as that of the tree from whence it was taken; and the grafting for all sorts being always performed in spring, from about the end of January, until that of March, the grafts unite firmly the same season, shoot forth in summer, so as by autumn, of the same year, they will often form shoots or young branches, from about a foot, to two or three long, and in some sorts will bear fruit the second or third year.

Hence the great utility of Grafting is to propagate any approved variety of choice fruit-trees, &c. whereby they are with certainty preserved perfect in their kinds; and trees of all sorts may also be continued and multiplied by the same method of propagation: for as just hinted, the grafts or cions, i. e. cuttings of young shoots, being taken from any particular tree or shrub, and grafted upon others of the same genus; as, for instance, a golden-rennet apple upon a crab or any other kind of apple-stock, raised from seed or otherwise, the graft shoots up and becomes the tree, and bears golden-rennets the same in every respect as that of the tree from whence the cions were taken; so that Grafting is the principal certain method to continue any approved varieties: for although the different varieties of fruit have been accidentally obtained from seeds, yet sow the seeds of the finest sorts, they will degenerate

degenerate so greatly by seeds, that out of hundreds so raised, there probably may not be one tree which produces fruit like the original, or perhaps that possesses any good quality for eating; and the same is observable of all other fruits, so variable is seedling fruit-trees; and hence it was, that the ancients, finding there was no certainty in continuing and multiplying the approved varieties of fruit from seed, they invented the art of Grafting, and inoculation, both of which proving effectual and invariable, is still continued in the propagation of almost all the varieties of every genus of fruit-trees; for whatever be the stock or tree, on which you perform the Grafting, if of the same genus, the graft will grow freely, and always remain unalterably the same; that is, always producing the same sort of fruit as its parent tree, which renders grafting of general utility in gardening, but more particularly for fruit trees; though some sorts, as vines, figs, quinces, mulberries, currants, gooseberries, &c. are most commonly propagated by layers and cuttings of their branches, which striking root freely in the ground, shoot up into stem and branches, and, like the grafts, produce fruit also exactly the same as the tree from whence they were taken. But as most other sorts of fruit-trees succeed much better by Grafting and budding, that method is commonly practised in their propagation; many curious varieties of ornamental trees and shrubs may also be propagated with certainty by Grafting and budding, particularly all the striped and variegated-leaved varieties, as also all other varieties of any particular species.

By Grafting also, different sorts of fruit and flowers of the same genus, may be made to grow upon one tree; as for instance, grafts of several sorts of apples may be ingrafted into the same tree, each graft branching out, produces fruit in every respect like that of the tree from whence they were cut; by the same rule you may also, for curiosity, have several sorts of pears on one tree, also apples and pears on the same tree or branch, as being all of the same fraternity or genus, the same is also observable of all other trees of the same genus or family; for it is in but very few instances that trees of a different genus will grow upon each other, by Grafting or budding, though the almond, peach, and nectarine, being all of the genus *Amygdalus* will grow upon the *Prunus* or plum-tree, and which is the common stock on which these

kinds are usually worked, but these kinds excepted, all other kind of fruits succeed best upon stocks or trees of their own family.

Of the proper Stocks, &c. to graft upon.

With respect to the stocks, or trees, on which to perform the operation of Grafting, it is most commonly performed upon the stems of young trees, raised from the seed, layers or cuttings for that purpose; though they are the most commonly raised from seed, except in particular cases; and when designed for the purpose of Grafting upon, are always denominated stocks, which, when from about the size of a goose quill, to an inch or more in diameter, are of due size for receiving the grafts; observing, that previous to the insertion of the grafts, the head of each stock must be cut off, from within about six inches to as many feet of the ground, according whether the tree is designed for a dwarf, or a half, or full standard; and one graft is commonly inserted into each stock, though in large stocks sometimes two or more grafts are inserted: remarking, that if intended to raise dwarf-trees, the stock, at the time of grafting, must always be headed down within a few inches of the ground, for the insertion of the graft; and for standards, the heading of the stock for the insertion of the graft may either be near the ground, and train up one of the first shoots from the graft to form a stem; or if you design the stock to form the stem, as is common for standard cherries, &c. it must be suffered to grow six or seven feet high, so head it at four, five, or six feet height for the reception of the grafts.

But Grafting is also performed upon old trees, or such as already bear fruit, particularly when it is designed to change the sorts, or have more than one sort on the same tree; or to renew the whole, or any particular branch of a tree: in either case, inserting the graft into the upright branches; sometimes heading the branches down for its reception, and sometimes inserting it into their sides without heading them down. But as there are five or six different methods of Grafting, each is exhibited below.

The particular sorts of stocks proper for Grafting each sort upon, is fully exhibited under each respective article as they occur in the course of this work.

Let it however be remarked, both in Grafting and inoculation, that, as above noticed, the different varieties of each genus, whether

whether fruit-trees, forest-trees, shrubs, &c. must always be grafted upon stocks or trees of the same family, or such that are very near kindred by the *characters* of their flower, otherwise they will not succeed; as for example, apples should be grafted only upon apple-stocks, i. e. young trees raised from the kernels of any kind of apple whatsoever: they will however also grow upon pear and quince stocks, as being all of the same genus; but they always succeed best upon any kind of apple-stocks, raised either from the kernels of the wild crab, or those of any of the cultivated apples. Pears likewise succeed best upon pear-stocks, or to have them dwarfs, are grafted upon quince-stocks. Plums should be grafted principally upon plum-stocks, though they will grow upon those of cherries, and cherries upon these, they being all of the same genera; but each succeed considerably best upon their own stocks. Cherries should therefore likewise be grafted upon cherry-stocks: but for particulars of each kind, see the several articles under their respective genera.

As to the method of raising the different sorts of stocks for Grafting, it is most commonly by seed, kernels, or stones of the respective fruits, sowed in autumn or spring, in beds of good earth, covering them with mold about an inch or two deep, according to their sorts or sizes; they will come up early in summer, and be fit to plant in nursery rows, two feet asunder, in winter and spring following; and in the spring after, many of them will be fit to whip-graft; but when they are from two to five or six years old, they will be suitable for one or other of the several methods of Grafting.

Stocks are also sometimes raised by layers and cuttings of the young shoots of particular trees of each respective genus, when designed to have stocks for Grafting particular varieties of fruit upon, as exhibited under their proper articles.

Stocks are likewise raised from suckers arising from the roots of the trees of the respective sorts, transplanting them into the nursery in autumn; to remain a year or two, and then may be grafted.

But the particular stocks and method of raising them is fully exhibited under the respective articles, which see; also the articles NURSERY and STOCKS.

Of the proper Grafts.

The grafts or cions, with which the Grafting is effected, are young shoots of the

last summer's growth, for they must not be more than one year, and such that grow on the outside branches, and robust but moderate shooters, such also that are firm and well ripened, should always be chosen from healthful trees, observing, that the middle-part of each shoot is always the best grafts: cut at the time of Grafting, to five or six inches in length, or so as to have four or five good eyes or buds, but should preserve them at full length till Grafting time, then prepared as hereafter directed.

They should be collected or cut from the trees in February, in mild weather, before their buds begin to swell, or advance much for shooting: in collecting them, chuse such as have not made any lateral or side shoots; cut them off at full length, and if they are not to be used as soon as they are collected, lay their lower ends in some dry earth in a warm border till Grafting time, and if severe weather should happen, cover them with dry litter.

Necessary Materials used in Grafting.

The proper tools and other materials used in Grafting, are

A strong knife for cutting off the heads of the stocks, previous to the insertion of the graft, also a small hand-saw for occasional use in cutting off the heads of large stocks.

A common Grafting-knife, or strong, sharp pen-knife, for cutting and shaping the grafts ready for insertion; also to slope and form the stocks for the reception of the grafts.

A flat Grafting-chissel and small mallet for clefting large stocks, in cleft-grafting, for the reception of the graft.

A quantity of new bass-strings for bandages, for tying the grafted parts close, to secure the grafts, and promote their speedy union with the stock.

And, a quantity of Grafting-clay, for claying closely round the grafts after their insertion and binding, to defend the parts from being dried by the sun and winds, or too much liquified by wet, or pinched by cold; for these parts ought to be so closely surrounded with a coat of clay in such a manner as effectually to guard them from all weathers, which would prove injurious to young grafts, and destroy their cementing property, so as to prevent the junction; therefore, a kind of stiff loamy mortar must be prepared of strong fat loam, or in default thereof, any sort of tough binding clay, either of which should

should be laid in an heap, adding thereto about a fourth of fresh horse-dung free from litter, and a portion of cut hay, mixing the whole well together, and add a little water, then let the whole be well beaten with a stick upon a floor, or other hard substance; and as it becomes too dry, apply more water, at every beating turning it over, always continue beating it well at top till it becomes flat; which must be repeated more or less according to the nature of the clay, but should be several times beaten the first day; and next morning repeat the beating, still moistening it with water, and by thus repeating the beating six or eight times every day for two or three days, or every other day at least, for a week, it will be in proper order for use; observing it should be prepared a week at least before it is used, but if a month the better.

Time and Method of Performing the Work of Grafting.

The season for performing the operation of Grafting is February and March, though, when the work is performed in February, it for the general part proves the most successful; more especially for cherries, plums, and pears, and March Grafting is well adapted for apples.

There are different methods of Grafting in practice, termed, Whip-grafting—Cleft-grafting—Crown-grafting—Cheek grafting—Side-grafting—Root-grafting—and Grafting by approach or inarching; but Whip-grafting and Cleft-grafting is most commonly used, and Whip-grafting most of all, as being the most expeditious and successful of any.

Whip-grafting.—This being the most successful method of all Grafting is the most commonly practised in all the nurseries; it is always performed upon small stocks, from about the size of a goose-quill, to half an inch or a little more or less in diameter, but the nearer the stock and graft approach in size the better; and is called Whip-grafting, because the grafts and stocks being nearly of a size, are sloped on one side, so as to fit each other, and tyed together in the manner of whips, or joints of angling-rods, &c. and the method is as follow:

Having the cions or grafts, knife, bandages, and clay ready, then begin the work by cutting off the head of the stock at some clear smooth part thereof; this done, cut one

side sloping upward, about an inch and half, or near two inches in length, and make a notch or small slit near the upper part of the slope downward about half an inch long, to receive the tongue of the cion; then prepare the cion, cutting it to five or six inches in length, forming the lower end also in a sloping manner, so as exactly to fit the sloped part of the stock, as if cut from the same place, that the rinds of both may join evenly in every part; and make a slit so as to form a sort of tongue to fit the slit made in the slope of the stock; then place the graft, inserting the tongue of it into the slit of the stock, applying the parts as evenly and close as possible; and immediately tie the parts closely together with a string of bafs, bringing it in a neat manner several times round the stock and graft; then clay the whole over near an inch thick on every side, from about half an inch or more below the bottom of the graft, to an inch over the top of the stock, finishing the whole coat of clay in a kind of oval globular form, rather longways up and down, closing it effectually about the cion, and every part, so as no sun, wind, nor wet may penetrate, to prevent which, is the whole intention of claying; observing to examine it now and then, to see if it any where cracks or falls off, and if it does, it must be instantly repaired with fresh clay.

This sort of Grafting may also be performed, if necessary, upon the young shoots of any bearing tree, if intended to alter the sorts of fruits, or have more than one sort on the same tree.

By the middle or latter end of May, the grafts will be well united with the stock, as will be evident by the shooting of the graft; then the clay should be wholly taken away, but suffer the bafs bandage to remain some time longer, until the united parts seem to swell, and be too much confined by the ligatures, then take the tying wholly off.

Their farther culture is directed under the respective articles, whether designed for dwarfs or standards, &c.

Cleft-grafting.—This is called Cleft-grafting, because the stock being too large for Whip-grafting is cleft or slit down the middle for the reception of the graft; and is performed upon stocks from about one to two inches diameter.

First, with a strong knife cut off the head of the stock, or if the stock is very large, it may be headed with a saw; and cut one side

sloping upwards about an inch and half to the top; then proceed with a strong knife or chissel, to cleave the stock at top, cross-way the slope, fixing the knife or chissel towards the back of the slope, and with your mallet strike it, so as to cleave the stock about two inches, or long enough to admit the graft, keeping it open with the chissel; this done, prepare the cion, cutting it to such length as to leave four or five eyes, the lower part of which being sloped on each side, wedge-fashion, an inch and half, or two inches long, making one side to a thin edge, the other much thicker, leaving the rind thereon, which side must be placed outward in the stock; the cion being thus formed, and the cleft in the stock being made and kept open with the chissel, place the graft therein at the back of the stock the thickest side outward, placing the whole cut part down into the cleft of the stock, making the rind of the stock and graft join exactly; then removing the grafting chissel, each side of the cleft will closely squeeze the graft, so as to hold it fast; it is then to be bound with a ligature of bass, and clayed over, as observed in Whip-grafting, leaving three or four eyes of the cions uncovered.

If intended to graft any pretty large stocks or branches by this method, two or more grafts may be inserted in each; in this case the head must be cut off horizontally, making no slope on the side, but smooth the top, then cleave it quite a-cross, and place a graft on each side, as the stock may be cleft in two places, and insert two grafts in each cleft; they are thus to be tied and clayed as in the other methods.

This method of Grafting may be performed upon the branches of bearing trees, when intended either to renew the wood, or change the sort of fruit.

Towards the latter end of May, or the beginning of June, the junction of the graft and stock in either methods, will be effectually formed, and the graft begin to shoot, when the clay may be taken off, and in a fortnight or three weeks after, take off also the bandages.

Crown-grafting.—This kind of grafting is commonly practised upon such stocks as are too large to cleave, and is often performed upon the large branches of apples and pear-trees, &c. that already bear fruit, when it is intended to change the sorts, or renew the tree with fresh-bearing wood, and is termed

Crown-grafting, because the stock or branch being headed down, several grafts are inserted at top all around betwixt the wood and bark, so as to give it a crown-like appearance; observing that this kind of Grafting should not be performed until March, or early in April, for then the sap being in motion, renders the bark and wood of the stock much easier to be separated for the admission of the graft.

The manner of performing this sort of Grafting is as follows:

First cut off the head of the stock or branch with a saw horizontally, and pare the top smooth, then having the grafts, cut one side of each flat, and somewhat sloping, an inch and half long, forming a sort of shoulder at top of the slope to rest upon the crown of the stock; and then raising the rind of the stock with a wedge, so as to admit the cion between that and the wood two inches down, which done, place the grafts with the flat side next the wood, thrusting it down far enough for the shoulder to rest upon the top of the stock, and in this manner may be put three, four, five or more grafts in one large stock or branch.

When the grafts are all thus inserted, let the whole be tied tight and well clayed, observing to leave two or three eyes of each graft uncovered, but raising the clay an inch above the top of the stock, so as to throw the wet quickly off, without lodging about the grafted parts, which would ruin the whole work.

Crown-grafting may also be performed, by making several clefts in the crown of the stock, and inserting the grafts round the top into the clefts.

The grafts will be pretty well united with the stock, and exhibit a state of growth by the end of May, or beginning of June, and the clay may then be taken away.

The trees grafted by this method will succeed extremely well, but for the first two or three years, have this inconvenience attending them, of being liable to be blown out of the stock by violent winds, which must be remedied by tying long sticks to the body of the stock or branch, and each graft tied up to one of the sticks.

Cheek grafting.—Cut the head of the stock off horizontally, and pare the top smooth, then cut one side sloping an inch and half, or two inches deep, and cut the lower part of the graft sloping the same length, making a sort of shoulder at top of the sloped part;

it

it is then to be placed upon the sloped part of the stock, resting the shoulder upon the crown of it, bind it with bafs, and finish with a covering of clay as in the other methods.

Side-grafting.—This is done by inserting grafts into the fides of the branches without heading them down, and may be practised upon trees to fill up any vacancy, or may do it for variety, to have feveral forts of apples, pears, plums, &c. upon the fame tree.

It is performed thus: fix upon fuch parts of the branches where wood is wanting to furnifh the head, or any part of the tree, there flope off the bark and a little of the wood, and cut the lower end of the grafts to fit the part as near as poffible, then join them to the branch, and tye them with bafs, and clay them over.

Root-grafting.—This is done by Whip-grafting cions upon pieces of the root of any tree of the fame genus, and plant the root where it is to remain; it will take root, draw nourifhment, and feed the graft.

Grafting by Approach or Inarching.—This fort of grafting is, that when the ftocks defigned to be grafted, and the tree from which you intend to take the grafts, either grow fo near, or can be placed fo near together, that the branch or graft may be made to approach the ftock, without feparating it from the tree, till after its union or junction with the ftock; fo that the branch or graft being bent to the ftock, they together form a fort of arch; it is called Grafting by Approach, or Inarching, and as being a fure method, is commonly practifed upon fuch trees as are with difficulty made to fucceed by any of the former ways of Grafting, as hinted in their propagation.

When intended to propagate any kind of tree or fhrub by this method of Grafting, if the tree, &c. is of the hardy kind, and growing in the full ground, a proper quantity of young plants for ftocks muft be fet round it; and when grown of a proper height, the work of inarching muft be performed, or, if the branches of the tree you defign to graft from is too high for the ftocks, in that cafe ftocks muft be planted in pots, and a flight ftage muft be erected around the tree, of due height to reach the branches, and the pots containing the ftocks muft be placed upon the ftage.

As to the method of performing the work; obferve, that in this method of Grafting, it is fometimes performed with the head of the ftock cut off, and fometimes with the head

left on till the graft is united with the ftock, though by previously heading the ftock, the work is much eafier performed; and having no top, its whole effort will be directed to the nourifhment of the graft; having however the ftocks properly placed, either planted in the ground, or in pots around the tree to be propagated; then make the moft convenient branches approach the ftock, and mark on the body of the branches the parts where they will moft eafily join to the ftock, and in thofe parts of each branch pare away the bark and part of the wood two or three inches in length, and in the fame manner pare the ftock in the proper place for the junction of the graft, then make a flit upward in the branch, fo as to form a fort of tongue, and make a flit downward in the ftock to admit it; let the parts be then joined, flipping the tongue of the graft into the flit of the ftock, making the whole join in an exact manner, and tye them clofely together with bafs, and afterwards cover the whole with a due quantity of clay, as before directed in the other methods.

After this, let a ftout ftake be fixed, if poffible, for the fupport of each graft, to which let that part of the ftock and graft be faftened, which is neceffary to prevent their being difjoined by the wind.

The operation being performed in fpring, let them remain in that pofition about four months, when they will be united, and the graft may then be feparated from the mother-tree; in doing this, be careful to perform it with a fteady hand, fo as not to loofen or break out the graft, flogging it off downwards clofe to the ftock; and if the head of the ftock was not cut down at the time of Grafting, it muft now be done clofe to the graft, and all the old clay and bandage muft alfo be cleared away, and replaced with new, to remain a few weeks longer.

Obferve however, that if you fhall think the grafts are not firmly united with the ftock, in the period of time above-mentioned, let them remain another year till autumn, before you feparate the grafts from the parent tree.

By this kind of Grafting, you may raife almoft any kind of tree or fhrub, which is often done by way of curiofity, to ingraft a fruit-bearing branch of a fruit-tree upon any common ftock of the fame fraternity or genus, whereby a new tree bearing fruit, is raifed in a few months; this is fometimes practifed upon orange and lemon-trees, &c. by Graft-

ing bearing-branches upon stocks raised from the kernels of any of the same kind of fruit, or into branches of each other, so as to have orange, lemons, and citrons all on the same tree.

GRASS, Grass Lawns, &c. for ornament to pleasure-gardens.

In modern gardening, a spacious Grass lawn extended in the front of the main habitation is the prevailing taste, where, by its constant verdure, summer and winter, and open rural extension, exhibits a fine imitation of nature at all seasons, especially when each side-boundary terminates in rural plantations in various irregular concave, and convex curves, to take off all appearance of formality. Rural Grass openings are also continued between the plantations throughout the different districts of the pleasure ground, separating and bounding the shrubbery clumps, &c. in some places widely spread, in others more contracted; in either case, extended to the boundaries of the several plantation compartments, in various irregular sweeps and curves, which renders the whole rurally ornamental; and is agreeable and more easy to walk on than gravel between the plantations in dry hot weather in summer.

Straight Grass walks prevailed greatly in the antient style of gardening, both for ornament and common walking; but in both these considerations, they are improper for general use, being attended with several inconveniences; those for ornament, unless they are elegantly wide and spacious, they have a littleness in their general appearance, as is observable in many places where long narrow slips of Grass are extended to a great length, by way of walks; and with regard to having Grass walks for common walking, they are very improper in winter, and all moist weather; also even in summer, in mornings and evenings, as being then always damp and dewy, which renders them very uncomfortable, as well as unsafe to some, with respect to health, to walk on them; and by constant walking and wheeling upon, they are often rendered bare, like a path, so as to appear very unsightly; Grass walks therefore, should be but sparingly introduced, and when intended to have any, either for variety, ornament, or summer's walking, let it be spacious, not less than fifteen or twenty feet wide, if extended to any considerable length.

The method of laying or making all Grass-work in gardens, is either by sowing it with

Grass-seed, or by laying it with turf, cut from a fine common or down, the latter of which, where it can be obtained at a moderate expence, is greatly preferable; it not only at once forms a complete sward, but is generally more close, even, and smooth, not apt to run up to benty Grass, or grow rank, nor rise in tufts.

In preparing the ground either for sowing or laying with turf, the whole ground must be broken up equally a moderate spade deep, clearing out all roots of perennial weeds; and then having stakes or wooden pegs, levelled in by notches, for your mark of level, agreeable to the laws of proportion, and the position of the ground, proceed with line and spade, to rough-level it, according to the said mark or level on the pegs, and then tread or ram the whole down equally, that it may not where sink in hollows hereafter; this done, work off your levels more accurately, and finish the whole with a neat raking, clearing off all large stones, making an even and smooth surface; and it is then ready, either for sowing with seed, or to be laid with turf.

As it may in some places be the most convenient to sow the ground with Grass seed, and in others, to lay it with turf, we will exhibit both methods separately.

By Seed.

By sowing with seed.—If intended to sow the ground with Grass-seed, as may be the case for large spaces of ground, or where turf cannot be conveniently obtained, the season for sowing it is February, March, and April, and will come up fine and green in a month or six weeks; and if sown in August or September, in moist weather, it will also rise very fast and thick before winter. The chief article is to procure good seed; those from under a common hay-stack, or out of a hay-loft, are often used, which may do very well, provided the hay was the growth of some fine pasture free from weeds, and affords naturally fine turf when grazed and mowed, but without attending to these particulars, there are often a mixture of various sorts, weeds and all, whereby the sward will be very irregular and foul, and never make handsome Grass. If you are not furnished with seeds of your own, they may be obtained cheap enough of the seeds-men; it must be sowed by broadcast, very thick and regular, and directly rake it in, and roll it when the surface is dry with a wooden roller, which will bury the feed

feed more effectually, and make a smooth surface; when the Grass comes up, pull up all weeds, and, the same season when the sward is become thick and green, and advanced some inches, it should be mowed, and after this roll it well, and so continue mowing it, &c. two or three times the first summer, especially if it was sowed in spring; and the oftener it is mowed and rolled, the thicker and finer it will grow, observing, if intended to keep the Grass tolerably fine, mowing will be requisite once a week or fortnight according to its growth, from April until October, and should be rolled once a week in all open weather the year round.

By Turf.

Laying the ground with turf, when turf can be easily procured, should always be greatly preferred to seed for Garden-grass, for the reasons before mentioned, and the best turf for that purpose is, that of a fine pastured common or down, where the sward is fine and the Grass short.

The season for laying turf is any time from September till April or May, though it will grow at almost any time of the year, even if there is occasion to lay it in summer, and dry weather succeed; for although it will divide or open wide at the joints, and turn brown as if dead, yet after the first rain it will close again, and resume its verdure.

The turf for this use, is cut or slead with an iron instrument called a turving-iron, which see, observing to cut them all an equal width, length, and thickness; the proper size is a foot wide, yard long, and about an inch thick; they should be first marked by line, the proper width, length, and depth, with a racer or rutter. See RACER. Racing them first long ways a foot wide, then across in yard lengths, then proceed to cut them up, having particular regard to cut them level, all an equal thickness, otherwise it will be impossible to lay them level; as you cut, a man or boy should roll each turf up close and tight, the Grass side inwards, and pile them up by tens, especially if they are cut by the hundred.

If they are cut by the hundred, the price is from six-pence to a shilling, according to the nature of the soil, whether soft and easy to cut, or hard or stoney; and a man will cut from three to five, six, or seven hundred in a day, or more, if very soft easy cutting turf, having a person to race them out and

roll them up, turf and turf as they are cut, out of the way of the cutter.

As to the method of laying them, it is very easy; they are to be laid regular, turf and turf, unrolling them as you lay them, joining them up quite close edge to edge, making good all deficiency of broken parts as you go on; and as soon as laid, it should be well beaten with broad heavy wooden beaters, being flat pieces of elm or oak plank, two inches thick, fifteen or eighteen inches long, and a foot broad, having a long handle fixed slanting in the middle of the upper side; and with these beat the grass regularly all over, and then roll it well with a heavy iron or stone roller, and the work is finished, observing, the beating and rolling should be repeated in moist weather.

If very dry hot weather succeeds, so as to occasion the turf to shrink and open at the joints, a good watering will be of much advantage; do not however, be under much anxiety about this, for, as before hinted, the first rain will join all close, and recover the verdure of the Grass effectually.

Its general management throughout the Year.

The culture necessary for garden Grass, is frequent mowing in summer, to keep it short and fine like a pastured down; poleing occasionally with a long pole, to scatter the worm-casts, which so greatly deface all grass; frequent rollings both to take up the scattered worm-casts to make the surface clean, and to render it smooth and firm.

As to mowing; to keep Grass in gardens very neat, mowing it once a week or ten days during the summer is necessary, especially for the principal home-lawns, and other Grass-ground in the most conspicuous parts of the garden, which parts should always be kept very close and fine, like the sward of a fine pastured down or common: the mowing of garden Grass is performed with a short-Grass scythe, see MOWING, and SCYTHE, &c. observing, that dewy mornings, or moist weather must always be chosen for that work, for it will be impossible to mow short Grass properly in dry weather. But previous to mowing, it is of great advantage to pole and roll the Grass the day before you intend to mow; in performing the mowing, great attention is necessary not to score, i. e. leave the mark of each stroke of the scythe, which has a very unsightly appearance; to prevent which, as much as possible, have your scythe laid out rather

rather wide, an inch or two beyond heel and toe, especially for very short Grass; and in mowing, keep the point rather out, and do not draw that part too fast toward, gathering your Grass neatly to the left in a range, and having mowed to the end of the swarth, mow it lightly back again, to trim off all scores, and other irregularities, unavoidably left the first time.

As soon as you have done mowing, proceed to sweep up the mowing, each swarth regularly by standing in the middle, sweeping it along alternately to the right and left to the end of the swarth, forming all the Grass thereof in a range on each side, then sweep up the ranges in large heaps, and carry the whole off directly in a wheel-barrow or large basket.

Poleing the Grass. This is performed with a long taper pliable ashen-pole, fifteen or eighteen feet long, to break and scatter the worm-casts about, i. e. those little lumps of earth cast up by the worms all over the surface of the Grass and greatly deface it; but by using the pole, when they are moderately dry, sweeping it backward and forward upon the Grass, breaks the earthy lumps into small particles, and scatters them about, and if the Grass is afterwards rolled with a wooden roller when the surface is a little moist, but not too wet, the earth will all adhere to the roller, and render the surface perfectly clean; observing this work should be repeated, as you shall see occasion the year round, and in mowing time, if the surface is foul, it is particularly necessary to pole and roll on the day previous to mowing, whereby, having a clean smooth surface, you will be able to mow close, even, and expeditiously.

Rolling garden Grass, is performed occasionally with a wooden roller, and a heavy iron or stone roller: a wooden roller is proper always after poleing as observed above, to clean up the worm-casts and smooth the surface, observing this work should never be performed when the surface is very wet, especially if full of worm-casts, as it would plaister and daub the grass very much, and render it unsightly; a heavy iron or stone roller should be used occasionally, to press down all inequalities close, so as to preserve a firm, even, smooth surface. Rolling is always of particular service, performed occasionally the day before mowing, as it greatly contributes to the easy and exact performance of that work; the work of rolling is in small, or but moderately large gardens, always perform-

ed by men, but in very extensive grounds, it is done by horse, having a large roller for that purpose, with shafts like a cart, &c. and the horse should at that time wear leather shoes, very broad at bottom, made to lace on occasionally like men's half-boots.

In some places the Grass is greatly defaced in May and June by the vast quantities of wild daisies daily arising, to remedy which, as much as possible, I have had the blade of an old broad-sword, fixed in the end of a long pliable pole, and as a sword cuts both ways, by sweeping it backwards and forwards, it will head down the daisies a great pace, which may be repeated two or three times a week, or as often as there may be occasion.

GRAVEL. Gravel-walks are 'great ornaments to gardens, as well as the most useful kinds of walks for common walking.

The best Gravel for walks is that which is composed naturally of irregular pebbles and flints, having a moderate proportion of a yellowish or brownish sandy loam, to make it bind and give colour; which kind of Gravel is the most common and valuable of all for walks, and is obtained in fields and commons in most parts of England, at about from one to three or four feet under the surface, though not equally good in all parts in respect to quality and colour; some may have a greater or lesser quantity of pebbles, a larger or smaller quantity of loam, the loam more or less sandy or clayey; and as to colour, it is the colour of the loam principally which constitutes the beauty of Gravel-walks, and that of a deepish yellow, or reddish colour is the most eligible, as when formed into walks well laid and rolled, is exceedingly beautiful and ornamental, and where such Gravel can be procured within a moderate distance, and easy expence is preferable to all other; but in some parts, the Gravel is of an iron-mould colour, or of a dusky brown hue, which may nevertheless be of a proper quality for walks, provided the colour can be dispensed with, and as the most esteemed high coloured Gravel is not to be met with every where, we must be content with such as nature affords.

It must however be remarked, that of whatever colour the Gravel, its proper quality for walks is, such as has a due proportion of moderate loam, to make it bind close and firm at all seasons, but not so redundant in loam, nor so clayey as to be clammy and stick to the feet in wet weather, nor too sharp and sandy,

sandy, to become open and loose in dry weather.

In some places, however, there is no other gravel but such as is very loose, sandy, or pebbly, having scarcely any binding materials amongst it, which kind of gravel will never of itself bind, but always remain open and loose, and be at all times disagreeable to walk on: this, therefore, should be mended with a mixture of loam, where practicable, adding about one load to every two or three of gravel, casting them together, and turning them over two or three times, that they may be well blended and incorporated; and this, when formed into a walk, will bind close, firm, and smooth at all seasons.

In preparing the gravel for your walks, it should by no means be screened, as is often the practice, only as it is dug out of the pit, cast it up in a heap, or long ridge, and all such large rough pebbles only as roll down, should be cleared away; for if screened from the stones, it will partake too much of the loam, as always to stick to the feet at every flash of rain, but by raking out just only the large rough stones, it will be sufficiently fine, and the walk formed of such will always be fit for use.

Gravel for walks, if it is to be purchased, is from about two to five or six shillings per cart-load for three horses; though the price is different in different parts, and according to the nature of the Gravel; but about London, if they cart it home from the pits, it is commonly five or six shillings per load, or more according to the distance, and sometimes they carry a load and a half at once, in the same cart, which is charged accordingly.

As to the distribution of Gravel walks in gardens, both for ornament and use, a magnificent walk of Gravel is necessary to proceed immediately parallel with the house, proportionable to its grandeur, extending each way in proportion to the width of the garden; and according to the former style of gardening, a large grand Gravel walk was usually extended in a straight line from the front of the habitation, along the middle of the pleasure ground, sometimes having grass plats continued on each side, and sometimes spacious borders furnished with curious shrubs and flowers. But in modern designs the above middle walk is rarely admitted, especially in spacious gardens, having nothing in front beyond the parallel walk, but an open rural grass lawn, free from all interfections of walks, &c. however, a grand walk closely

parallel to the house, as observed above, is indispensibly necessary, both for ornament and use; and from this, side walks should branch off, communicating with the other parts of the garden, one in particular to be laid in a serpentine turn quite round the ground, others leading in the same manner through the interior parts, so as to have dry firm walking at all times to every part of the garden without walking upon the grass, which sometimes may be wet and disagreeable.

As to the dimensions for Gravel walks, they are to be regulated according to the extent of the garden, so may be from five to twenty feet or more wide, the length indeterminate; but all principal walks should be at least ten or twelve feet wide; and in large gardens, that leading directly from the house should be fifteen or twenty feet wide at least; tho' where the house and gardens are magnificent, the main walks contiguous to the mansion are sometimes made thirty or forty feet wide; the boundaries on each side is sometimes of grass widely extended, and sometimes are bounded by borders for flowers and other curious plants, having either narrow verges of grass, or edgings of dwarf box, or thrift, &c. next the walk.

According, therefore, to the above rules, stake out the width of the walk, and proceed to form the boundary, each side of equal level, corresponding to the adjacent ground, and form the cavity of the walk for the reception of the gravel; observing that the whole space must be digged at least ten or twelve inches deep, to allow for a proper depth of gravel, both to prevent weeds rising from the ground below, and worms from casting up the earth therefrom; as also to allow for turning the gravel occasionally when the surface becomes foul: the earth digged out to form the cavity of the walk, may be used to raise and form the ground on each side, if necessary, which, and the edgings, should always be completed before you begin to lay the Gravel.

Every thing being ready for the reception of the Gravel, then you may in the first place lay any hard rubbishy materials in the bottom, several inches thick; such as any coarse gravel or ballast, or any rough stoney rubbish, which can be best procured, which will greatly prevent worm-casts, and help to drain the moisture from the top of the walk: the proper gravel is then to be laid six or eight inches thick at least; as you proceed in laying, observe to raise the middle higher than the sides,

in a gradually rounding form, which is not only necessary to throw off the wet, but also to give the walk a more ornamental appearance; the proportion to be observed in this is, that for a walk of five or six feet width, an inch and half rise in the middle may be sufficient; one of ten or twelve feet, two and a half; and one of twenty feet, four or five inches rise will be enough; observing nearly the same proportion in any width whatsoever, and by no means raise the middle much higher, which would render the walk both uneasy to walk upon, and of disagreeable appearance; being particularly attentive to form the rise all the way gradually rounding from both sides to the middle, laying every part very exact and even; and at every ten or fifteen feet as you advance in laying, it is proper to tread, rake, and roll it, for gravel always rolls more firm and smooth whilst it is fresh stirred; besides, it is necessary for fear of rain happening; for which reasons also, you should never lay more in one day than you can finish off, except to rough lay it; the treading should therefore be performed regularly with the feet pretty close, taking short steps; which work being necessary to render every part equally firm, and so as not to sink in holes when you rake and roll it. The raking should be performed lengthwise, and a rake without teeth is the most eligible, or, in default thereof, use the back of any common rake occasionally, whereby you will be able to smooth the surface very evenly without drawing off the larger pebbles, or raking them into holes or heaps, as is unavoidable in using the teeth of a rake; for the art of smooth-raking is to leave all the top stones equally dispersed over the surface. As soon as it is raked, let it be well rolled, both across and lengthways; and when the whole is laid, give a good rolling the whole length, repeating it till the surface is rendered perfectly compact, firm, and smooth; and if after the first shower of rain, you give it another good rolling, it will bind like a rock.

The management of Gravel walks, to keep them perfectly neat the year round, is occasional weeding, sweeping, and good rolling once or twice a week; and when the surface becomes very foul with weeds or moss, as is often the case, the walk must be broken up in spring, and turned, the surface to the bottom, and the bottom to the top, whereby the weeds and moss will not only be buried, but

by turning up the fresh gravel, the walk will appear as fresh as when new laid. But the custom of breaking up gravel walks in the beginning of winter, in rough ridges, to remain in that useless and unsightly manner till spring, to destroy weeds, &c. as is thought, is a very wrong practice, for the intention has rather the contrary effect; and the walks are thereby not only rendered useless for almost one half of the year, but at a time when there is hardly any dry or sound walking upon grass or other parts: besides these inconveniencies, the walks appear not only unsightly in themselves, but give also a very disagreeable look to the adjacent parts of the garden: let the walks therefore always remain undisturbed, at least till spring, when, if necessary, they may be turned.

Rolling should be performed once a week at least, but if two or three times the more beautiful the walks will appear, and tend greatly to destroy weeds and moss: it is, however, a general rule among gardeners, to sweep and roll every Saturday; and during summer it is of much advantage to give a good rolling after rain, which will preserve a compact smooth surface.

Turning gravel is a sort of slight digging, turning the foul surface down and the fresh up, which being necessary, as above observed, when the surface is full of small weeds, or very mossy, and which is the only effectual method of destroying them; besides, the work of turning is necessary once every year or two in spring, to turn up the fresh gravel to give the surface a lively appearance during summer; therefore some make it a rule to turn their principal Gravel walks every spring; and the proper time is April, when the weather is become settled and fine: in performing the work of turning, give every spit a clean turn, so as to turn the surface down, and the fresh gravel to the top; and as you go on, tread, rake, and roll, every ten or fifteen feet, as observed in new laying the walks.

GREEN-HOUSE, a garden-building fronted with glass, serving as a winter residence for tender plants from the warm parts of the world.

A very considerable share of the vegetable creation that grow naturally in distant warm climates in open fields, &c. at all seasons, which in their culture in this climate require protection in winter; observing, however, those of the Green-house department being only from the warmer parts of the world, require

quire protection only from frost, not needing aid of artificial heat, like stove-plants, from the hottest regions, except in very intense weather; when the aid of a moderate fire, burned either within the house, or in a furnace without, in the end or back wall, communicating the heat to flues or funnels ranging along the inside. Though there may not be occasion for any fire once in two or three years, yet it is advisable in constructing a Green-house to erect flues to use occasionally, which will prove serviceable, not only in severe frosts, but also in long moist foggy weather; a moderate fire now and then will dry up the damps, which would otherwise prove pernicious to several of the tender kinds of plants.

We will first exhibit a general sketch of the dimensions of a Green-house, then give a list of all the principal Green house plants usually cultivated in the English gardens, together with their general culture.

A Green-house should generally stand in the pleasure-ground, and, if possible, upon a somewhat elevated and dry spot, full to the south, and where the sun has full access from its rising to setting; the building is commonly of brick or stone, having the front almost wholly of glass-work; and must range lengthways east and west, with the front directly facing the south, and should generally be constructed upon an ornamental plan. As to its general dimensions, with respect to length, width, and height, it may be from ten to fifty feet or more long, according to the number of plants you design it shall contain; and its width may be from ten or fifteen to twenty-four feet; though for a middling house fifteen or eighteen feet is a sufficient width; and its height in the clear, should be nearly in proportion to the width: but as to the erecting rooms over it, as is commonly directed, I should advise to have none, as being not only an unnecessary expence, but gives the building a heavy look, for all garden-buildings should have a light airy appearance.

The walls in the back and ends should be carried up two bricks, or about eighteen inches thick; though if the building is to be more than fifteen feet high, the walls should be two bricks and a half thick; and at one end of the back wall, withoutside, it is eligible to erect a furnace for burning fires occasionally, as before observed, communicating with flues within, ranging in three or four returns along the back wall, also one flue running along

the front and end walls, close to or just under the floor; all of which will be extremely serviceable in time of intense frosts, and very damp foggy weather; and as to the front of the building, it should have as much glass as possible, and a wide glass door should be in the middle, both for ornament and entrance, and for moving in and out the plants; and it would be convenient to have also a smaller private door at one end: the width of the windows for the glass sashes, may be five or six feet, and the piers between the sashes may be either of timber, six, eight, or ten inches wide, according to their height, or if of brick or stone work, must be two feet wide at least, to be duly substantial, sloping both sides of each pier inward, that by taking off the angles, a freer admission may be given to the rays of the sun: for the same reason have the bottom of the sashes to reach within a foot of the floor of the house, and their top reach almost as high as the ceiling; and if brick or stone piers two feet wide, shutters may be hung within to fall back against each pier: the roof may either be half glass-work, next the front; the other half slated, especially if the upright or front piers are of timber; and shutters to cover the top glasses may be contrived to slide under the slated roof: but if the piers are of brick or stone, it is common to have the roof entirely either slated or tiled, but slating is the most ornamental, either for a half or whole roof; and the ceiling within should be lathed, and which, as well as the whole inside-wall, should be well plastered and white-washed.

But in the modern construction of Green-houses, in order to have as much glass as possible in front, the piers between the sashes are commonly of timber only, from six to eight or ten inches thick, according to the height, so as to admit as great a portion of light and heat of the sun as may be; and on the same consideration, continue glass-work sloping half way up the roof, the other half slated, as above observed; and sliding shutters also contrived to slide under the slated roof, to draw down occasionally in severe weather, or in time of hail storms, to defend the glasses; and for the front, may have either wooden or canvas shutters, or large canvas cloths upon rollers, to let down occasionally, or, in default thereof, nail up garden-mats in severe weather.

Sometimes Green-houses for large collections of plants, have two wings, of smaller dimensions, added to the main building, one

at each end, in a right line, separated sometimes from it by a glass partition, with sliding sashes for communication, and the front almost wholly glass-work, and half glass roofs as above hinted; thus by these additional wings, the Green-house consists of three divisions, whereby the different qualities and temperatures of the various plants can be more eligibly suited. The middle or main division may be for all the principal and more hardy, woody or shrubby kinds, which require protection only from frost; one of the wings may be appropriated for the succulent tribe, and the other wing for the more tender kinds that require occasional heat in winter, yet can live without the constant heat of a stove.

On whatever plan the Green house is constructed, let the whole inside, both cieling and walls, be neatly finished off with plaister and white-wash, and all the wood-work painted white; and the bottom paved with large square paving tiles.

The necessary utensils of the Green house are principally some treffels or stands for the support of boards, on which to arrange the pots of plants, so as to have their heads range in a gradual slope from the back part to the front; but as some of the plants may be tall and in large tubs, and either do not require stands, or cannot be easily placed thereon, such must be regulated as you shall see convenient.

From the above general sketch, any one may form an idea of the principal dimensions of a Green-house, which he may enlarge or diminish as it may suit his convenience.

Green-house Plants.

We will now proceed to exhibit, at one view, a list of the principal Green-house plants, having recourse for particulars to each respective genus.

AGAVE, *Agave* or *American Aloe*.—Common great American Agave, with entire green leaves, and a branching flower-stalk.—Common Agave, with striped leaves.—Virginia Agave, with narrower pale green leaves. (*All succulent plants.*)

ALOE, *African Aloes*.—Mitre shaped Aloe.—Tree, or Sword Aloe.—Aloe Ferox.—Fan Aloe.—Succotorine Aloe.—Soap Aloe.—Partridge-breast Aloe.—Tongue Aloe.—Warted-tongue Aloe.—Pearl-tongue Aloe.—Cob-web Aloe.—Hedge-hog Aloe.—Cushion Aloe.—Spiral Aloe.—Pentangular Spiral Aloe.—Triangular Spiral Aloe.—*Iris Uvaria* Aloe; this Aloe will also live in a warm border.—(*All succulent.*)

ANDROMEDA, Tree Andromeda, or Carolina Sorrel-tree.—(*Shrubby.*)

ANTHERICUM, *Spider-wort*.—Shrubby, stalked, onion-leaved Anthericum—Aloe-leaved Anthericum—Mock-asphodel Anthericum. (*Succulent.*)

ANTHOLYZA, *Æthiopian Corn-flag*.—Ringent Scarlet Antholyza—Æthiopian Crimson Antholyza—Cunonia, or large-spathæed scarlet-flowered.—(*Herbaceous.*)

ANTHOSPERMUM, *Amber-tree*.—Æthiopian Smooth Amber-tree—Ciliated Amber-tree.

ANTHYLLIS, Jupiter's Beard, or *Barba Jovis*.—Common *Barba Jovis*, or Silver Bush—Spanish ternate-leaved *Barba Jovis*—Dwarf Portugal *Barba Jovis*—Erinacea, or Prickly *Anthyllis*. (*All of shrubby growth.*)

ANTIRRHINUM, Snap-dragon. — Variegated Snap-dragon—Gibraltar spotted-flowered *Linaria*. (*Both of an herbaceous nature.*)

ARCTOTIS, *Arctotis*.—Rough-leaved Arctotis.—Narrow leaved Arctotis.—Sea Ragwort-leaved Arctotis.—Plantain-leaved Arctotis—Stalkless Arctotis; (are mostly of a shrubby nature, except the last sort.)

ARISTOLOCHIA, *Birth-wort*.—Evergreen Aristolochia—Pistolochia, or small Birthwort—Shrubby Birthwort. (The two first are herbaceous, the other shrubby.)

ARTEMISIA, *Mug-wort*.—Tree Wormwood.

ASCLEPIAS, *Swallow-wort*.—Shrub Asclepias.

ASPARAGUS. White Prickly Asparagus.—Declinated Bristly-leaved Asparagus—Acute-leaved Asparagus.—Retrofracted Great Prickly Asparagus: have all somewhat shrubby stalks.

ASTER, *Star-wort*.—Shrubby African Asters.

ASTRAGALUS, *Milk-vetch*, &c.—The *Tragacanth*, or Goats-thorn; several varieties. (*All shrubby.*)

ATROPA, *Deadly Night Shade*.—Shrubby Deadly Night Shade of Spain.

BACCHARIS, *Ploughman's Spikenard*.—Iva-leaved Baccharis—Oleander-leaved Baccharis—Halimus-leaved Baccharis. (*All shrubby.*)

BOSEA, *Yerva-mora*, or Shrubby Goldenrod Tree.

BRYONIA, *Briony*.—African Tuberous-rooted Briony. (*Herbaceous*)

BUBON, *Macedonian Parsley*.—Shrubby Galbaniferous Bubon—Shrubby Gummiferous Bubon.

EUPHTHALMUM, *Ox-eye*.—Shrubby Jamaica Ox-eye.—Maritime, or Sea Ox-eye.

BUPLEU-

BUPLEURUM, *Hare's-ear*.—Shrubby Æthiopian Hare's-ear—Shrubby Difforme-leaved Cape Hare's-ear.

CACALIA, *Foreign Colt's Foot*.—*Cacalia Fico-ides*—Kleinia, or Indian Cacalia—Anteuphorbium Cacalia—Papillary Cacalia. (Succulent.)

CACTUS, *Melon-thistle*.—Cactus Opuntia, or Common Indian Fig. (Succulent.)

CALENDULA, *Marigold*.—Shrubby Cape Marigold—Shrubby Grass-leaved Æthiopian Marigold.

CALLA, *Sweet Calla*, or Æthiopian Arum. (Herbaceous.)

CAMPANULA, *Bell-flower*—American Bell-flower—Canary Bell flower. (Herbaceous.)

CANNA, *Indian Flowering Reed*.—Common Indian Flowering Reed, and varieties—Glaucous Indian Reed. (Herbaceous.)

CAPPARIS, *Caper Bush*.—Spinous Capparis, or True Caper Shrub.

CASSINE, *Cape Phillyrea*.—*Maurocenia*, or Hottentot Cherry. (Shrubby.)

CEANOETHUS. — African Ceanothus. (Shrubby.)

CELASTRUS, *Staff tree*.—*Pyracantha*-leaved *Celastrus*—Box-leaved—Myrtle-leaved. (Shrubby.)

CERATONIA, *Carob-tree*.—Common Carob-tree, or St. John's Bread.

CHAMÆROPS, *Dwarf Palm*.

CHRYSANTHEMUM. — Shrubby Canary Chrysanthemum—Shrubby Floscular Chrysanthemum.

CHRYSOCOMA, *Goldy-locks*.—Shrubby *Coma Aurea*, or Greater African Goldy-locks—Shrubby Nodding Goldy-locks.
